consumer acculturation

Lisa Peñaloza

Consumer acculturation is defined as the general process of adaptation by consumers in the marketplace. While initially theorized for immigrants seeking economic opportunity and quality of life in another nation or fleeing situations of economic conflict or war at home (Peñaloza, 1994), distinct consumption patterns and market relations are forged by minority groups as well, as they adapt to mainstream and other groups in heterogeneous societies (Kjeldgaard and Askegaard, 2006). Such interaction and adaptation is increasingly widespread globally, as families and communities extend beyond national borders. The growing importance of the topic is evident from the 80 odd participants of over 20 nationalities at the May 2009 conference on Immigration, Consumption and Markets organized by Nil Toulouse and Soren Askegaard in Lille, France.

The scope of this body of work is broad, in examining social and market learning and interaction at individual, family, community, societal, and transnational levels (Lindridge, Hogg, and Shah, 2004; Askegaard, Arnould, and Kjeldgaard, 2005; Parreñas, 2005; Nolin, 2006; Peñaloza, 2007). Patterns of adaptation include a varied, dynamic mix of assimilating new consumption tastes and skills, maintaining old ones, resisting new and old forms, swapping or alternating between them (Oswald, 1999; Visconti, 2005), and forming distinctively hybrid consumption patterns based on localized interpretations of global media and market artifacts (Kjeldgaard and Askegaard, 2006) within global labor (Peñaloza, 1995) and financial imperatives (Üçok, 2007).

Consumer research challenges include distinguishing consumption practices across groups and calibrating changes in cultural skills, values, and knowledge, as inflected by social class, race, ethnicity, gender, religion, nationality, and geographic differences, and as played out in increasingly diverse intra- and transnational social and market formations. As cultural artifacts and behaviors are detached from the people creating them and appropriated by other consumers and corporations globally (Grier,

Brumbaugh, and Thornton, 2006), concerns of cultural hegemony and homogenization among minority groups coincide with concerns with loss of status and power by the mainstream group, as both seek to maintain cultural identity and integrity. These concerns gain currency with the decreasing size of mainstream cultural groups and as minority consumer subcultures are incorporated by marketers within nations and in market diaspora across the globe.

Work on marketer acculturation examines how marketers learn to serve consumers of various cultures and address them in ways sensitive to relations between groups (Peñaloza and Gilly, 1999). Carried further, acculturation research can provide insight into the identity and vitality of nations by examining the nature of group relations as diverse people coexist and adapt their respective ways of life in consumption, in markets, and in communities. The issue is the role of business in separating, uniting, legitimizing, and excluding groups of people, as tailoring products and services to the mainstream advances, its dominance, even as targeting groups outside a cultural mainstream enables their members to reproduce vital cultural patterns and meanings and thrive. Public policies restricting the language and other cultural expressions of those who are “different” or “other” and excluding them in markets and other social services are the means by which one group dominates the others (Üstüner and Holt, 2007). Such intolerance increases in adverse economic circumstances and may be accompanied by violence, and yet such intolerance can trigger politically oriented consumption and market incorporation that ultimately advances the identity and community of those otherwise excluded (Peñaloza, 2007).

Further research opportunities lie in documenting how market development relies on and fosters forms of difference. Ultimately, the market both integrates and separates (Keating and McLoughlin, 2005). In their integrative function, markets assemble various people under a particular rubric and provide them with the cultural legitimization of a market. Other promising areas of work are investigating the nature of market participation played out within cities and nations, and exploring how immigrants and other minorities attain forms of

consumer sovereignty that potentially inform by and impact political participation. It remains to be seen how capitalism and democracy will continue to cross-fertilize each other, with immigrants and minorities serving as test cases.

subcultures

Robert V. Kozinets

Contemporary consumer culture is filled with a rich gallery of subcultural archetypes, including rappers, gangstas, punks, surfers, jocks, fanboys, goth girls, metalheads, Trekkers, and hackers. These subcultures provide meanings and practices that significantly structure consumers' identities, relationships, and behaviors in many ways. They offer up rich, meaningful, group identities that differentiate from, oppose, or even seek to subvert normal mainstream ways of speaking, thinking, and behaving. With their resistant, activist, symbolic characteristics, subcultures are closely related to countercultures and often serve as the source of countercultural images and identities. These images and identities are often absorbed by the advertising, entertainment, and marketing industries, and eventually become popularized and commonplace mainstream activities. Subcultures thus fuel the never-ending engine of differentiation that underlies contemporary consumer culture (Heath and Potter, 2004).

In consumer research or consumer cultural studies, subcultures have been related to sports and avocations, fantasy and escape, mass media fans, brand consumption, as well as gender and class (Belk and Costa, 1998; Celsi, Rose, and Leigh, 1993; Kozinets, 2001; Schouten and McAlexander, 1995). Different aspects of consumption-related subcultures have been emphasized by consumer researchers, including their mode of acculturation (Celsi, Rose, and Leigh, 1993), their self-selection and hierarchical, ethos-driven structure (Schouten and McAlexander, 1995), as well as their relationship to mass-mediated meanings and images, resistance, and activism, and online communities (Kozinets, 2001, 2002; Kozinets and Handelman, 2004).

John Schouten and Jim McAlexander (1995, p. 43) coined the useful term *subculture of consumption* to refer to and underscore the importance of these consumption-oriented groupings, defining the term as "a distinctive subgroup of society that self-selects on the basis of a shared commitment to a particular

product class, brand, or consumption activity." They also summarized and suggested some key characteristics of these groups: their shared ethos, mythos, values, and beliefs; their social structure based on hierarchies of commitment and authenticity; their shared language and rituals; and the religious and transformational aspects of the subcultures. However, linking consumer culture to the subcultures literature (e.g., Hebdige, 1979) has drawn some criticism. Some argue that "the social groups investigated in the name of 'subcultures' are subordinate, subaltern or subterranean" or are "deviant," "debased," illegitimate or of lower socioeconomic status" (Thornton, 1997, p. 4) or that the term is ambiguous and negatively charged (Hannerz, 1992). A further critique holds that the term has been overextended to refer to a variety of different leisure activities and hobbies, rather than to actual ways of life or social forms. In response to these and related critiques in sociology and anthropology, a number of other conceptions, including "cultures of consumption" (Kozinets, 2001), "microcultures" (Hannerz, 1992), "brand communities" (Muniz and O'Guinn, 2001, *see* BRAND COMMUNITY), and "consumer tribes" (Cova, Kozinets, and Shankar, 2007) have been proposed and used.

Yet despite the ever-present ambiguities of the term, the concept of subcultures is still very useful to consumer researchers and others who are interested in understanding consumer behavior in its actual, lived sense. The term deals with an ambiguous, dynamic, and countercultural phenomenon with a long history, strong momentum, and deep ties to consumer culture. The underground connotations of the term *subculture*, its established links to foundational cultural studies literature, and its inherent flexibility will continue to inspire new generations of researchers for many years to come. As long as lifestyle, differentiation, self-transformation, and small group identities continue to play an important part of consumers' lives in contemporary consumer culture, the concept of subcultures will help us to better understand the complex social world around us.

social class

David K. Crockett

WHAT IS SOCIAL CLASS?

Although no single precise definition exists, most scholars acknowledge that social class is composed of a variety of factors such as wealth (especially inherited wealth), income, occupational status, educational attainment, and residence. Arnould, Price, and Zinkhan (2002, p. 181) provide a useful working definition: *social classes are groupings across society, broadly recognized by members of that society, involving inequalities, or certainly, differences in such areas as power, authority, wealth, income, prestige, working conditions, lifestyles, and culture*. Social class is by nature hierarchical, that is, groups and individuals receive unequal amounts of power, prestige, and esteem (i.e., status). Social class is pervasive, if often invisible. The mere mention of it may invite feelings of superiority among members of the elite, or feelings of uneasiness among those at the bottom of the status hierarchy.

One important component of social class is income. In fact many people think income is synonymous with class. However, even though income largely determines lifestyle at any given point in time it is a poor indicator of social class. In much of the developing world, accurate income data is difficult to obtain, and in developed nations income can fluctuate wildly over the life course (Leonhardt, 2005). Hence, instead of income many organizations and institutions use *purchasing power parities* to make cross-national comparisons where costs of living and currency values can be quite different.¹

HOW DOES SOCIAL CLASS IMPACT CONSUMER BEHAVIOR?

Scholars have historically sought one-to-one relationships between income (usually indexed with education and occupation) and consumption, where high status consumers purchase brand X while lower status consumers purchase comparably more brand Y. In contemporary consumer culture however, the lowest and highest status consumers often choose the same products (Schor, 1998). Consequently, the old

economic approaches are giving way to cultural approaches that generate insights about social class and consumption by focusing on *how* people consume rather than *what* they consume (Holt, 1998). People consume their way up the social class hierarchy by utilizing three types of status-generating resources: economic capital, social capital, and cultural capital (Bourdieu, 1984). Cultural approaches emphasize social and cultural capital (while economic approaches emphasize only economic capital). Social capital refers to membership in formal and informal reference groups. Cultural capital refers to skills, knowledge, tastes, and preferences derived indirectly from family background, class heritage, and common experience. Higher status comes from consuming in ways that signal a person's store of social and cultural capital relative to others.

WHAT ARE THE SOCIAL CLASS SEGMENTS?

The particular distribution of individuals into social class groupings varies widely from country to country. Most countries feature at least three segments (upper, middle, and working class), with the most fully formed class structures in the developed world. The upper class can include upper-upper and lower-upper subsegments. The former is usually characterized by inherited wealth, while the latter is often characterized by "nouveau riches" (or new money). Many, if not most consumption trends are indexed to the tastes of these two subsegments (Schor, 1998). The upper middle class, despite lower stores of economic capital than the upper class, is typically more similar to the upper classes than to other members of the middle class in aspirational lifestyles, culture, and values. The remainder of the middle class is the primary target of most marketing efforts aimed directly at consumers. The majority of the world's people, however, belong to the working class or the chronically poor. Working-class consumers are difficult to characterize globally, other than by their very limited economic resources. In developed nations, they are thought to basically enjoy the core features of their current lifestyles and have little incentive to fundamentally alter them (other than to have more resources). Finally, the chronically poor or underclass largely lack

access to most basic consumer choices. World Bank researchers estimate that one-quarter of the developing world fits in this group, living on less than \$1.25 per day in 2005 prices (Chen and Ravallion, 2008).

impulsive and compulsive buying

Ronald J. Faber

Impulsive and compulsive buying are terms that are frequently confused for each other, but represent behaviors that differ greatly in regard to their frequency, cause, outcome, and severity. Impulsive buying is a more common and ordinary behavior. Virtually everyone makes a purchase on impulse (without much deliberation) from time to time. Some do this more frequently than others. Nonetheless, almost everyone finds that sometimes they are able to resist the desire to buy on impulse and at other times they give in to this impulse. It has been suggested that impulse buying occurs when desire for a product or brand outweighs one's willpower to resist (Hoch and Loewenstein, 1991).

On the other hand, compulsive buying is a psychological disorder where one experiences an urge to buy that cannot be controlled. Failing to act on this urge creates increasing tension for the individual which only dissipates with buying. Frequently, this urge is triggered by negative events or feelings. Ultimately, this behavior leads to extreme negative consequences (financial and/or personal) for the individual (Faber and Christenson, 1996; O'Guinn and Faber, 1989). Many compulsive buyers never use the items they purchase.

IMPULSE BUYING

Historical development of impulse buying. Early research on impulse buying in the 1950s and 1960s viewed it as occurring anytime a consumer made any unplanned purchase. As a result, research sought to classify certain types of products as impulse items and looked at what store characteristics encouraged impulse buying. This approach changed in the 1970s as researchers began to realize that all products could be purchased impulsively. As a result, research on impulse buying began to focus on characteristic of individuals, rather than of products or stores, and to define the term as a sudden and powerful urge in the consumer to buy immediately (Rook and Hoch, 1985; Rook, 1987).

Correlates and causes of impulse buying. Factors that influence both the desire for a product and willpower to resist this desire are related to situations when impulse buying occurs (Hoch and Loewenstein, 1991). Proximity to a purchase can increase wanting for an item. Thus one technique to reduce impulse buying is to walk away from an item and only buy it if you still want it as much several minutes later. Another factor that correlates with impulse buying is mood state. People indicate they are much more likely to buy on impulse when in a positive mood (Rook and Gardner, 1993).

Willpower has also been shown to effect impulse buying. Vohs and Faber (2007) showed that people were more likely to buy on impulse when their self-regulatory resources (willpower) were diminished. Engaging in self-regulation in some other domain increases the likelihood people will buy on impulse. Thus, not shopping after a long, difficult day and keeping shopping trips short can help people to cut down on impulse buying.

COMPULSIVE BUYING

Historical development of compulsive buying.

Compulsive buying was initially discussed in the psychiatric literature under the term *onomania* almost 100 years ago (Kraepelin, 1915). However, there was little discussion of it from the mid-1920s until the late 1980s when researchers in the United States, Canada, and Germany all began to report on this problem (d'Astous, Maltais, and Roberge, 1990; O'Guinn and Faber, 1989; Scherhorn, Reisch, and Raab, 1990). The Compulsive Buying Scale (Faber and O'Guinn, 1992) was developed to distinguish compulsive buyers from other consumers. Using this measure with a national probability sample, Koran *et al.* (2006) estimated that 5.8% of the US population may be compulsive buyers.

Correlates and causes of compulsive buying. Many compulsive buyers have personal or family histories of other problem behaviors such as alcoholism and drug abuse, eating disorders, and impulse control disorders. The most commonly reported correlates of compulsive buying are psychological ones. Numerous studies have found that compulsive buyers

2 impulsive and compulsive buying

are perfectionists, and have low self-esteem and high levels of depression and anxiety. Compulsive buying seems to provide temporary relief from these negative feelings, but ultimately makes compulsive buyers feel even worse about themselves. Thus, compulsive buying appears to be more about obtaining short-term relief from negative feelings than about a desire for specific goods. Several studies have found that compulsive buying is unrelated to income.

customer satisfaction

Richard L. Oliver

INTRODUCTION

This article describes the general field of consumer (customer) satisfaction behavior as it is currently conceptualized. Though the field has been researched from many perspectives, the most common appearing in the areas of satisfaction attribute (feature) *surveys* and customer satisfaction *strategy* (see CUSTOMER SATISFACTION/DISSATISFACTION), more psychologically based approaches are now practiced.

Here, the underlying mechanisms of how consumers construct, consciously or subconsciously, their satisfaction conclusions are explored so that greater satisfaction fostering and dissatisfaction avoidance can be ensured. Readers interested in greater detail and elaboration, including discussion of topics not covered here, should consult the author's original work (Oliver, 2010) and an earlier short treatise on satisfaction research (Oliver, 2006).

CUSTOMER SATISFACTION DEFINED

Recent interpretations in the consumer domain now couch satisfaction as a fulfillment response. Fulfillment implies that a consumption goal is known, as in basic motives of hunger, thirst, and safety. However, observers of human behavior understand that these and other goals can be and frequently are modified and updated in various ways. Thus, consumer researchers have moved away from the traditional meaning of satisfaction and now pursue this concept as the consumer experiences and describes it.

In Oliver (2010, p. 8), the following definition has been proposed as being consistent with the conceptual and empirical evidence:

Satisfaction is the consumer's fulfillment response. It is a judgment that a product or service feature, or the product or service itself, provided (or is providing) a pleasurable level of consumption-related fulfillment, including levels of under- or over-fulfillment.

Here, pleasurable implies that fulfillment gives pleasure or reduces pain. Thus, individuals can be satisfied so as to return to normalcy, as in the removal of an aversive state. Moreover, fulfillment is not necessarily limited to the case of met needs. Overfulfillment can be satisfying if it provides additional unexpected pleasure; and underfulfillment can be satisfying if it gives greater pleasure than one anticipates in a given situation. Note that if the word "displeasure" is substituted for pleasure in the satisfaction definition, dissatisfaction results. Thus, the displeasure of underfulfillment typically is dissatisfying and overfulfillment may be dissatisfying if it is unpleasant – "too much of a good thing."

A SATISFACTION MODEL USEFUL FOR CURRENT THINKING

At this point, it would be helpful to envision the framework upon which this discussion is based. If one can construct the antecedents of the satisfaction response, that is, how a consumer mentally constructs satisfaction, many conceptual nuances will be revealed. Perhaps the most useful model of this process is the expectancy disconfirmation framework that proceeds as follows. The model assumes that consumers have prior expectations of the product or service performance.

Expectations, whether measured before or after consumption (predicted or recalled retrospective expectations), and performance are compared to form an "objective" (or gap) disconfirmation level; objective disconfirmation provides the basis for a subjective interpretation of this expectation–performance difference, and subjective disconfirmation is one direct cause of satisfaction. Additionally, there may exist a direct effect of performance on satisfaction not channeled through disconfirmation. This represents the "expectancy disconfirmation with performance model."

The performance of features (attributes). In a familiar research scenario, consumers are asked to retrospectively rate the product or service on the degree to which each feature was delivered. Concurrently, the consumer may be asked to rate the product on an overall basis or on satisfaction.

2 customer satisfaction

Despite the ubiquity of this method, problems are inherent in its implementation. One is that the list of features cannot be exhaustive for all consumers. A second problem arises from the disparate goals (needs) of consumers. Another problem is that of the relevance of features at different stages of decision-making.

Satisfaction drivers versus choice criteria. In pursuing the reasons behind the consumer's satisfaction response, it should be borne in mind that the researcher's goal is to determine the correct feature list of *satisfaction drivers*, as opposed to product or service *choice criteria*. A common mistake is that of assuming the features consumers use in selecting a product from a list of alternatives are identical to the set of features that play into satisfaction and dissatisfaction judgments.

Thus, for this reason, customer satisfaction researchers (see CUSTOMER-SATISFACTION RESEARCH) are advised to determine satisfiers and dissatisfiers independently of choice determinants. Additionally, this also illustrates why a satisfaction measure is preferred to one of, say, attitude (see ATTITUDES) or quality, if consumer satisfaction is the goal of the firm. Both attitude and quality judgments are used in choice and thus may give a distorted picture of the features most strongly related to satisfaction.

Expectations and their role in satisfaction. Generally, an expectation is an anticipation of future consequences based on prior experience and other many and varied sources of information. Expectations can also be described as a *comparative referent* for performance. The reason is that performance alone is an unreferenced concept. Meaning is attached only when performance can be compared to some standard. In fact, any number of referents can be used in later satisfaction assessments, but they become channeled into expectations when the product or service is purchased. The concept of needs, discussed previously, is one of the many referents available to consumers. These same consumers, however, will pursue only those products that they *expect* to fulfill their needs.

Frequently, consumers express different variations of what they would prefer a product to deliver. At one level, they may have an ideal

perception of a product offering, something they wish they could receive in a perfect world. Others, or the same consumers at a different time, expect only what they believe the firm's product can or will deliver. Researchers have referred to these two different perceptions as *ideal* and *predicted* expectations or, alternatively, as *should* and *will* or *desired* and *likely* outcomes.

A number of research investigations have established that consumers do indeed recognize and use multiple levels of expectations or standards. Among the most common of these are studies investigating the influence of normative (should) and predicted (will) expectations, or alternatively, ideal and expected referents. The results of all studies tend to be similar. When the ideal or should level of expectations was the referent, satisfaction was lower than when actual expected or predicted expectations were used. Moreover, these studies generally conclude that consumers do entertain multiple standards and that inclusion of more than just the predicted level may improve a model's ability to understand satisfaction.

Disconfirmation and its role in satisfaction. When consumers compare performance to their expectations, the response of *disconfirmation*, more specifically, disconfirmation of preperformance standards, results. Because the early work in consumer satisfaction was conducted with predictive expectations as a standard, the phrase "disconfirmation of expectations" or "expectancy disconfirmation" has come to apply to this concept. Many standards consumers bring to the consumption experience can be disconfirmed, so an alternative phrase to describe the discrepancy from a standard could be simply "disconfirmation."

However, because the phrase "disconfirmation" without a valence qualifier is ambiguous as to direction, the phrase "negative disconfirmation" is commonly used to refer to the negative discrepancy that occurs when performance is below standard, and "positive disconfirmation" is used to refer to the positive discrepancy that occurs when performance is above standard. When performance is equal to standards or expectations, a simple confirmation of expectation exists.

Disconfirmation is “generic” with numerous applications. For example, the entire consumption experience can be judged on the degree to which it was better or worse than was expected, as can individual attributes. Other possibilities include dimensions (attribute groups) of performance and the benefits (good aspects) reaped from consumption as separate from the problems (bad aspects) encountered.

Objective (calculated) versus subjective disconfirmation. Early attempts to measure disconfirmation used a discrepancy or “gap” approach. That is, separate survey sections were used to capture, first attribute expectations and, later attribute performance perceptions. Then the performance scores were subtracted from their respective expectation scores and these “gaps” were added. The logic is direct. When attribute performance was higher than its respective expectation, the gap is positive and is considered favorable. Similarly, when expectations were higher, the gap was negative and unfavorable. Satisfaction should increase as the positivity of the gap score increased and it should decrease (contributing to dissatisfaction) with the negativity of the gap score.

Is there evidence for the superiority of subjective disconfirmation (better/worse than) over calculated disconfirmation in the prediction of satisfaction? Yes. A number of studies have examined both the calculated and single-score varieties of disconfirmation, most using rating scale scores. The results of all studies were similar with the majority of the evidence suggesting that the subjective version of disconfirmation correlates more highly with satisfaction scales than do the discrepancy scores. Moreover, when analyzed in an ordering of cause and effect, the following configuration of concepts, as shown in Equation (1), is consistently found to best fit the data:

$$\begin{aligned} &\text{calculated disconfirmation} \\ &\quad \Rightarrow \text{subjective disconfirmation} \\ &\quad \Rightarrow \text{satisfaction} \end{aligned} \quad (1)$$

This sequence of events forms the basis for the expectancy disconfirmation model of consumer satisfaction discussed here. As shown,

this sequence portrays a calculated expectation–performance discrepancy (if performed) as input to the consumer’s subjective interpretation of this difference. The subjective interpretation then becomes the most immediate antecedent of satisfaction. If no “objective” score is available, then a subjective judgment is “sensed.” Expectations and performance are implicitly incorporated in the disconfirmation judgment in this sequence.

Operation of disconfirmation in the satisfaction model. Reviews of studies measuring disconfirmation in various forms are now available to suggest that it is a powerful predictor of satisfaction, even when combined with expectation and performance in the manner discussed (Yi, 1990; Szymanski and Henard, 2001; Oliver, 2010). In fact, disconfirmation typically dominates expectation and frequently dominates performance in terms of the strength of effect. There are times, however, when both performance and disconfirmation are input to the same regression that the disconfirmation effect is obscured (becomes nonsignificant). The reason is multicollinearity as disconfirmation is a performance-based concept and both the performance and disconfirmation variables may be highly correlated. When this happens, two regressions must be run separately – the first containing performance and the second containing disconfirmation in its stead.

SHORT-TERM CONSEQUENCES OF SATISFACTION

Intention to repurchase. One of the most common results of satisfaction/dissatisfaction is a stated intention (*see* CONSUMER INTENTIONS) to repurchase (or not) in the future. Sometimes, this is posed in surveys in a hypothetical sense as in “if you were in the market for a (generic product), how likely would you buy a (specific brand)?” These scales are ubiquitous in the literature; in particular, it is unusual not to see them being used because the researcher rarely can observe repetitive behavior in a cross-sectional one-shot survey. In commercial research, however, intention scales may not be needed because actual repeat behavior is more easily obtained.

Still another version of intention is the degree to which the consumer splits purchasing between alternatives. Similar to multibrand loyalty, consumers may intend to repatronize one of a set of acceptable alternatives, such as in restaurant dining. In this case, an intention to repatronize a particular establishment is more akin to a probability across choices as opposed to a probability within a choice. It is known, however, that stated intentions without behavioral validation are very unreliable. Consumers frequently overstate their intentions due to a positivity bias in consumer responding. In lieu of other measures of satisfaction validation, however, intention data may be among the best measurement modalities one can achieve.

Complaining/praising. Perhaps the most neglected, infrequently found satisfaction-related concepts in satisfaction surveys are complaining and its polar opposite, praising. This is surprising as the complaining literature is vast and, in fact, was the first of the satisfaction concepts to be extensively studied. Complaining is important because, unlike dissatisfaction, complaining is a behavior. While dissatisfaction and complaining are related, they have been found to be imperfectly correlated. Not all dissatisfied consumers complain so that those who do are very disaffected. Nor are all “complainers” dissatisfied as they may be simply motivated to provide feedback to a firm so that it may improve a current marketplace offering.

In the same vein, the extent of complimenting or praising – the related bipolar concept of complaining – may also be of value to the firm. Praising is not as frequent as complaining, but it does occur. One might view it in the context of an extreme expression of satisfaction, having information value to the firm beyond high performance and satisfaction ratings. This could be particularly important in the service industry where many and varied service providers are involved.

Word of mouth and recommendations. Word of mouth (WOM) is the third post-satisfaction concept discussed here. The nature of recommendations is very closely intertwined with WOM. While WOM can consist of praising

or damning (to other consumers as opposed to the firm or its representatives), recommendations are targeted communications to potential purchasers. Note that “recommendations” is a general term and can be either positive (to buy) or negative (not to buy).

OTHER SATISFACTION-RELATED COMPARATIVE REFERENTS

The following are briefly mentioned here because they appear prominently in overall perspectives on the satisfaction response (Oliver, 2010).

Quality. The quality literature (*see* QUALITY FUNCTION DEPLOYMENT (QFD)) predates the satisfaction concept and, in some sense, promoted the emergence of focused attention on satisfaction. In effect, it is a comparison of performance to standards of excellence or perfection as in the four criteria of diamond evaluation (cut, clarity, color, karat weight). The number of citations to this concept is legend, and justice would not be served if any were listed as prototypical.

Equity/inequity. Equity, a comparison of performance to fairness standards, is similarly well-vested. Only a small number of satisfaction studies are available that tackle the core concept (e.g., Oliver and Swan, 1989). Most address unfair pricing (Campbell, 1999), or subdimensions, such as interactional fairness (Blodgett, Hill, and Tax, 1997).

Regret. Regret is of recent vintage, at least in consumer behavior, and is a comparison of performance to “what might have been.” Relying heavily on the concept of forgone alternatives, a complete summary can be found in Zeelenberg and Pieters (2007).

Value. This article ends with the concept of value which has taken two forms in the consumer literature. The most common is that of performance compared to sacrifice in acquisition, in effect, a benefit versus cost perspective (Zeithaml, 1988). The second is that of performance against goal attainment, or the second derivative of performance – its intended consequences (Woodruff and Gardial, 1996). The

latter is later subdivided into usage consequences and/or mere possession effects.

There is much more to the study and meaning of satisfaction and more is yet to come, as further discovery on this vast concept continues.

consumer innovativeness

Gerard J. Tellis and Eden Yin

Consumer innovativeness is a construct that deals with how receptive consumers are to new products. Knowledge of consumer innovativeness is crucial for a firm's success given that new products are essential for future growth and success, cost millions of dollars to develop, and their life cycles are becoming increasingly short.

Research on consumer innovativeness is extensive, and yet it has achieved little consensus in definition, measurement, and findings. Consumer innovativeness has been defined as a predisposition or propensity to buy or adopt new products (Midgley and Dowling, 1978; Hirschman, 1980; Steenkamp *et al.*, 1999; Tellis, Yin and Bell, 2009), a willingness to change (Hurt *et al.*, 1977; Im *et al.*, 2003), or a preference for new and different experiences (Hirschman, 1980; Raju, 1980; Venkatraman and Price, 1990).

The measurement of consumer innovativeness has varied greatly across studies partly because of the variation in its definition. The main scales developed to measure this construct are life innovativeness scales and adoptive innovativeness scale. An example of the former is the ability to introduce newness in one's life (Kirton, 1976). Examples of the latter are measuring innovativeness as a tendency to buy new products, which include Raju's scale (1980), Goldsmith and Hofacker's scale (1991), and Baumgartner and Steenkamp's (1996) exploratory product acquisition scale. One problem of these scales is that they have a large number of multiple items that are not substantially different from each other. Thus, the discipline can benefit from a parsimonious measure of consumer innovativeness.

On the basis of a review of the literature, Tellis, Yin and Bell (2009) identify at least ten dimensions of consumer innovativeness: novelty seeking, risk taking, variety seeking, opinion leadership, stimulus variation, habituation, nostalgia, suspicion, effort, and frugality. The first five of these are positively valenced while the latter five are negatively valenced. In a test of these dimensions across 15 countries of the world, Tellis, Yin and Bell (2009) found that the positively valenced measures are prone to

social desirability bias and yea saying, while the negatively valenced measures do not suffer from such a bias. Indeed, they found that three or four of the negatively valenced measures could provide a reasonably good estimate of consumer innovativeness across cultures and countries.

Another important measure used to capture consumer innovativeness is a concept called sales takeoff. *Sales takeoff* is the first dramatic increase in the sales of a new product in the early stage of its life cycle. Sales takeoff often marks the beginning of the growth stage of a product's life cycle and can signal its future evolution into a mass market product. Tellis, Stremersch and Yin (2003) and Chandrasekaran and Tellis (2008) use the time to takeoff as a measure for consumer innovativeness across countries. Their finding indicates that clear country clusters of consumer innovativeness emerge based on time to takeoff. For example, in Europe, Scandinavian countries are the most consumer innovative, followed by mid-European countries, and then Mediterranean countries.

Researchers have found some demographic correlates of consumer innovativeness are significant: age, income, education, gender, and mobility. For example, Steenkamp *et al.* (1999) found age to be significant and Steenkamp and Burgess (2002) found income and gender to be significant drivers of consumer innovativeness. In the largest cross-country study on consumer innovativeness, Tellis, Yin and Bell (2009) found age, education, gender, income, and mobility to be significant drivers of consumer innovativeness. Their study is based on data from 5569 consumers across 15 major nations and 9 languages.

Demographics aside, consumer innovativeness is category specific. In particular, women are more eager to buy new home appliances, cosmetics, and food and grocery products, while men are more eager to buy new automobiles and sporting goods. Younger consumers are more eager to buy automobiles than other age groups. Highly educated consumers are more eager to buy financial service (Tellis, Yin and Bell, 2009). Consumer innovativeness also varies across countries and categories. For example, Japanese are most prone to buy new electronics, Brazilians to buy cosmetics, and Swedes to buy

food products (Chandrasekaran and Tellis, 2008; Tellis, Yin and Bell, 2009).

social networks

Jacob Goldenberg

A *social network* is usually defined as a graph of nodes, or actors, (e.g., in a marketing context, actors are individual consumers, families, or business entities) that are linked to each other in a meaningful way (e.g., through information exchange or friendship, in the case of individuals, or through trade or collaboration in the case of business entities). These networks are often complex, and social networks can be extremely large in marketing.

It is beyond the scope of this article to note all the works in this field. Several key terms are defined in the box.

In the last two decades, our understanding of social network properties has advanced significantly, and networks have become one of the most attractive fields of research for scholars of almost all social science disciplines, including computer sciences (computer-based networks), biology (e.g., networks of genes), physics, and chemistry. One of the most interesting features of network research is that researchers from diverse fields typically work on similar problems, use similar definitions, and they obtain consistent results concerning networks dynamics (as a result, a typical network paper includes references from multiple fields). Some examples of well-known network properties found to be common to many networks (briefly defined in the box) include a *high clustering coefficient* (Watts, 1999), *short distances or paths* (see Newman, 2001; Watts and Strogatz, 1998), a *scale-free degree distribution* (Albert and Barabasi, 2002; Amaral *et al.*, 2000; Barabási and Albert, 1999; Jeong *et al.*, 2000), and a common *betweenness centrality distribution* (Chen *et al.*, 2007; Kitsak *et al.*, 2007).

Social network literature can be classified into two research themes: (i) network formation (see among many others: Albert and Barabasi, 2002; Barabási and Albert, 1999; Davidsen, Ebel, and Bornholdt, 2002; Deroian, 2006; Kryssanov *et al.*, 2008; Kryssanov *et al.*, 2006; Watts, 1999; Zhang and Liu, 2006; Zhou and Mondragon, 2004) and (ii) information dissemination over networks and network connectivity (see among others: Brown, 1981; Goldenberg, Libai, and

Muller, 2001; Goldenberg *et al.*, 2005; Kocsis and Kun, 2008; Rogers, Ascroft, and Rolling, 1970; Valente, 1995; Young, 2006).

In the first research stream, recent efforts have been applied to understand how network structures and properties emerge, and to identify the local rules of behavior that generate the formation of these structures. One topic of study in this stream is scale-free emergence. Barabási and Albert 1999 mapped the topology of a portion of the Web, and reported two findings: some nodes (termed *hubs*) had an exceptionally greater number of links than other nodes, and the number of links connecting to a single node followed a power-law distribution. After discovering that several other networks, including social and biological networks, typically had heavy-tailed degree distributions, they called this structure a *scale-free network*. Amaral *et al.* demonstrated that most real-world networks can be classified into two broad categories according to the slope of the distribution (usually plotted on a log-log scale). Barabási and Albert proposed the *preferential attachment* mechanism to explain the appearance of this power-law distribution. This mechanism (with many variations) essentially assumes that any new node joining the network has a higher probability to link to a node with a higher degree. Alternative mechanisms, such as transitivity (in which a friend of my friend is likely to become my friend), have also been since suggested.

Marketing literature is more strongly oriented to the second research stream (for a recommended review, see Van den Bulte and Wuyts, 2007), with a recent focus on information dissemination, accepted as the core process driving innovation adoption (see Godes *et al.*, 2005; Goldenberg *et al.*, 2005; Hogan, Lemon, and Libai, 2005; Rogers, 2003; Trusov, Bodapati, and Bucklin, 2008; Valente, 1995; Van den Bulte and Joshi, 2007; Van den Bulte and Wuyts, 2007; Watts and Dodds, 2007). For example, a special session on networks was held at a recent Marketing Science conference, to discuss networks and related issues such as network population sampling (Ebbes *et al.*, 2008), the role of spatial proximity in diffusion (Barrot *et al.*, 2008), the economic value of social interactions (Stephen and Toubia, 2010), and a study of pharmaceutical social

networks (Iyengar, Valente, and van Den Bulte, 2008). Research has also empirically established the intuitive understanding that innovations propagate through peer recommendations and word of mouth, which are strongly dependent on the structure of the social network. Several additional interesting issues are presented briefly below.

THE STRENGTH OF WEAK TIES

Granovetter (1973) found that weak ties are sometimes more important than strong ties in information seeking and innovation dissemination. Strongly tied individuals form cliques that have a tendency to conformity. Owing to their fundamental similarity, any single clique member also knows more or less what the other members know. Therefore, to discover new information or gain new insights, clique members must look beyond the clique to other, more distant friends, and acquaintances. This weak-ties strength was found to have significant implications for consumer behavior issues.

SMALL WORLDS AND DEGREES OF SEPARATION

The scale-free structure is one explanation for evidence on the nature of the dissemination process and the role of high connectivity in this process: The hubs receive information first and spread it through the network. Another explanation is the small world structure and the high clustering coefficient (Watts and Strogatz, 1998).

The small world theory is based on the premise that any arbitrary pair of nodes in the network is linked by a genuinely short chain of individuals (nodes). The 1967 small world experiment by Milgram, 1967 gave rise to the famous phrase “six degrees of separation.” In this experiment, a sample of individuals was asked to reach a specific target person by passing a message along a chain of acquaintances (all pairs were in the United States). Successful chains (which reached their destination) turned out to be approximately six steps long, which is remarkably short. Note, however, that this finding may be biased by the fact that the majority of chains in that study actually failed to complete. Despite claims of the experiment’s

questionable methodology, it is widely accepted that a social network requires a small number of steps to connect all its members. A recent electronic small world experiment found that approximately five to seven degrees of separation are sufficient for connecting any two people through e-mail (Watts, 1999), although the majority of chains in this experiment were also not completed.

According to the small world model, most nodes are not neighbors of one another, but can be reached from any other node using only a small number of jumps. A small world network, where nodes represent people and edges (or links) that connect acquaintances, captures the phenomenon of strangers who become linked through a mutual acquaintance. Watts and Strogatz (1998) noted that networks can be classified according to two independent structural features: the clustering coefficient and shortest path (distance). Random networks, for example, exhibit a small shortest pathlength and a small clustering coefficient. Indeed, many real-world networks not only have a small average shortest pathlength but also a clustering coefficient significantly higher than expected by random chance. This alone explains the rapid dissemination of information that occurs over a network.

THE ROLE OF KEY INDIVIDUALS

Research suggesting that a relatively small number of people have substantial influence on the opinions and decisions of the majority can be traced back at least 50 years to the seminal work by Katz and Lazarsfeld (1955). Broadly speaking, influential people are thought to have three important traits: (i) they are persuasive (perhaps even charismatic); (ii) they know a lot (i.e., are experts); and (iii) they have large number of social ties, i.e., they know a lot of people.

Hyper-influential individuals (also known as *opinion leaders*, *mavens*, or *hubs*) are one class of consumers that has always attracted the attention of researchers and practitioners. Extensive studies of the behavior of agents in social systems have been conducted at the social and psychological level (Reingen and Kernan, 1986). While different terms for these agents are typically used interchangeably, the constructs are not identical. Opinion leaders

and mavens (Coulter, Larence, and Price, 2002; Feick and Price, 1987) are thought to have expertise in their area of influence, while hubs are individuals whose distinctive feature is their large number of social ties.

The literature on opinion leaders is relatively broad and opinion leaders have been studied in a variety of areas including marketing, public opinion, health care, communication, education, agriculture, and epidemiology. Until recently, researchers have broadly concurred that opinion leaders can have a major impact on opinion formation and change, and that a small group of influential opinion leaders may accelerate or block the adoption of a product in an entire market. Since 2008, this point has triggered heated debate. Some argue that influentials (or more precisely, individuals who represent nodes with an exceptionally large degree) have only a marginal influence on adoption speed (e.g., Watts and Dodds, 2007), yet according to counterarguments, influentials adopt sooner than other people. This occurs not because they are innovative but rather because influentials are exposed earlier to an innovation due to their numerous social links (e.g., Goldenberg *et al.*, 2009). As a result, highly connected individuals have a significant impact on the overall adoption speed of an innovation and in some cases even on the ultimate market size.

Social network metrics

Betweenness: Betweenness reflects the extent to which a node connects other pairs of nodes in the network (through the shortest path).

Centrality: Centrality reflects the social “power” of a node, based on how well it connects the network. The more common centrality measures are *degree*, *betweenness*, and *closeness*.

Closeness: Closeness reflects the proximity of all other individuals in a network (directly or indirectly) to the node. Closeness is the inverse of the sum of the shortest distances between each node and every other node in the network.

Clustering coefficient: The clustering coefficient measures the likelihood that two acquaintances of a node are acquaintances themselves: if A knows both B and C, a high coefficient in this network implies that the probability that B knows C is high.

Degree: The degree is the number of ties connected to each node.

Density: Network density is the proportion of ties in a network relative to the total number of possible ties.

Pathlength: Pathlength is the distance between pairs of nodes in the network.

Scale-free network: Scale-free networks have a degree distribution that is easy to view as a power law: $n(\text{degree} = x) = -ax^y$.

Structural cohesion: Structural cohesion is measured by the minimum number of nodes required to dismantle a group of nodes.

Structural equivalence: Structural equivalence is the extent to which nodes share a common set of ties.

persuasion

Michal Herzenstein

Persuasion is an active attempt to change beliefs, attitudes, preferences, or behaviors. The extent of persuasion is measured by changes to the above (measured before and after the persuasion attempt). This article focuses on various approaches to persuasion.

COGNITIVE APPROACHES

Persuasion will take place if cognitive processing, conscious or unconscious, has occurred. An example for conscious cognitive approaches is comparative judgment theory, which suggests that nothing is judged in isolation and everything can be seen as good or bad depending on what it is compared with (framing and prospect theory, Tversky, and Kahneman, 1979; contrast and assimilation effects, Hovland, Harvey, and Sherif, 1957). Examples for unconscious cognitive processes are implicit memory (Schacter, 1987) and mere exposure theories (Zajonc, 1968) that show that even under conditions of limited processing resources, exposure can influence judgment (albeit without awareness).

AFFECTIVE APPROACHES

People are persuaded because the communication evokes certain affects. Both positive affects (such as humor, love, or pride) and negative affects (such as fear, disturbance, or unpleasantness) are commonly induced. Persuasion occurs because people try to maintain their positive moods or avoid negative moods. One important theory that explains how to use emotions in persuasion is classical conditioning. On the basis of Pavlov's experiments with dogs, this theory suggests that pairing brands with positive unconditioned stimuli (familiar stimuli that automatically produce affective responses) will elicit the desired affective response toward the brand itself (rather than the stimuli). For example, a brand is paired with a familiar and loved tune in a commercial (Gorn, 1982). The tune elicits positive emotions that are paired with the brand. Afterwards, when the brand is encountered without the tune (i.e., in the store) it elicits the same emotions.

MOTIVATIONAL APPROACHES

Persuasion happens when people wish to be persuaded. Subtle motivational techniques are preferred over obvious persuasion attempts (Kardes, 2001). The most relevant principle is consistency—people like consistency and dislike inconsistency. They dislike it so much that they are willing to change beliefs, attitudes, and behaviors in order to eliminate the inconsistency. A famous example of this principle is cognitive dissonance (Festinger, 1957), which suggests that people strive for attitude–behavior consistency. When attitudes are inconsistent with past behaviors (dissonance), an unpleasant tension is produced, which motivates people to reduce that dissonance. The result is a shift in attitudes that increases attitude–behavior consistency.

SELF-PERSUASION

Persuasion that results from elaboration on the true merit of the brand leads to strong accessible attitudes, and therefore is preferred over persuasion that results from peripheral cues such as music or humor. Self-persuasion approaches try to understand how persuasive communications induce people to think more extensively about the brand or advocated position. One of the most useful models is the elaboration likelihood model of persuasion (ELM) (Petty and Cacioppo, 1981). ELM proposes two routes to persuasion: the central route—requires effortful processing of the message; and the peripheral route—requires minimal thinking. The central route leads to strong accessible attitudes, but it will be taken only when the recipient is both motivated and able to elaborate on the message.

SOCIAL INFLUENCE

Communicators who wish to move people in their direction should appeal to a limited set of deeply rooted human drives and needs. According to Cialdini (2001) there are six principles that lead to persuasion. (i) Liking—sellers should like their customers. People like people who like them, and they are more likely to say yes to them because they feel they are in good hands. (ii) Reciprocity—people want to give back to those who have given to them.

2 persuasion

Companies who give their clients something meaningful, tailored, and unexpected are often repaid. (iii) Social proof—people like to follow the crowd. Use the many to persuade the few. (iv) Consistency—when people make a public commitment, they almost always back those words with actions. (v) Authority—people like to follow the lead of legitimate experts. (vi) Scarcity—people are afraid to miss out or lose by not choosing something scarce.

In conclusion, persuasion can be attained in various ways, and choosing the proper appeal is crucial. Any communicator who wishes to move people in his or her direction should exercise some “detective work” and seek out the right time, and the right place, to put the right approach to use with his/her target audience (Cialdini, 2001).

consumer involvement

Judith Lynne Zaichkowsky

Involvement is a motivational variable in consumer behavior and can be defined as *A person's perceived relevance of the object based on inherent needs, values and interests* (Zaichkowsky, 1985, 1986). Involvement is used to describe the level of consumer interest, search, or complex decision making toward an object. The object of involvement may be a product, a service, a situation, or an advertisement. Low involvement implies inertia, and high involvement implies a great deal of activation and it is found to influence consumer decision making and interactive communications. A consumer's level of involvement can be used as a segmenting variable to further target the market by marketing managers.

The history of the term *involvement* in the marketing literature has two major roots: one in the advertising research literature (Krugman, 1965, 1967) and the other in the consumer behavior literature (Howard and Sheth, 1969). In applying learning theory to TV copy testing, Krugman 1965 found that when a series of ads were presented, those presented first and last were better remembered than those ads in the middle of the series. This finding showed the same primacy and recency effects found by Hovland 1957 in the learning of non-ego involving material. Krugman hypothesized what advertising and non-ego involving material had in common were low levels of involvement, and operationalized it as the number of "bridging experiences, connections or personal references" per minute that the viewer made between his own life and the advertisement. Therefore personal involvement impacted on response to advertising.

Consumer involvement in the marketing and consumer behavior literature grew out of the realization that a great deal of consumer behavior does not involve extensive search for information or a comprehensive evaluation of choice alternatives (Olshavsky and Granbois, 1979). The consumer makes dozens of mundane decisions and choices each day and it is inappropriate to assume consumers actively process and think about each decision (Kassarjian, 1978). In this domain, many studies looked at the act of

purchase, in addition to the product category itself, and determined the situations of purchase were highly influential in determining the level of consumer decision making activity (Clarke and Belk, 1978).

Because involvement was discussed in terms of products, advertisements, and purchase situations, early quantitative studies used various manipulations or single item measures and outcomes to represent and capture the concept. In a response to the plethora of definitions and measures, Zaichkowsky (1985) proposed a single definition and semantic differential scale to be used across all domains to capture the abstract concept of involvement on one dimension. Laurent and Kapferer (1985), on the other hand, proposed a measurement of product involvement which captured five facets or dimensions of product involvement: personal interest, importance of negative consequences, subjective probability of mispurchase, pleasure value, and sign value. These two studies represented the beginning of a long debate on how best to measure involvement.

It was clear that involvement was not only cognitive, but could also be emotional in nature (Petty, Cacioppo, and Schumann, 1983). The original Zaichkowsky Personal Involvement Inventory (PII) was later reduced to 10 items (Zaichkowsky, 1994) which better represented a balance of cognitive and emotional involvement items. This revised PII fitted in well with the idea that there are four quadrants in consumer behavior research: low and high involvement on one axis, and emotional and cognitive involvement on the other (Vaughn, 1988).

In recent years, the research literature indicates the concept of consumer involvement is widely embraced across a multiple of disciplines from agriculture (e.g., Verbeke and Vackier, 2004) to information systems (e.g., Koufaris, 2002). The role of involvement in consumer behavior has been so well accepted that it is completely incorporated in the field and no textbook in consumer behavior seems complete without a discussion of the topic.

consumer desire

Richard P. Bagozzi

As a scientific concept, desire is relatively new in consumer research. Two construals of desires have been proffered by consumer researchers. One is championed by Belk and colleagues (e.g., Belk, Ger, and Askegaard, 1997, 2003). These authors conceive of desires as “belief-based passions that involve longing, yearning, and fervently wishing for something” and can be expressed in metaphors for “hunger (or thirst), sexual lust, and addiction” (Belk, Ger, and Askegaard, 1997, p. 24). Belk, Ger, and Askegaard (2003) characterize desire as “a powerful emotion” (p. 343) observed in a state of tension between feelings of seduction and morality (p. 345) and distinguish it from wants and needs (p. 328). While derived from grounded research with consumers, this conceptualization of desires seems overly narrow, limited too much to biological kinds of desire, and exclusionary of less intense forms of everyday desire functioning in consumer behavior.

A second conceptualization of desire, while overlapping with that formulated by Belk, Ger, and Askegaard (2003), comes from the subfields of philosophy known as the *philosophy of mind* and the *philosophy of action* (e.g., Bishop, 1989; Davis, 1997; Mele, 2003). Davis (1997) distinguishes between volitive and appetitive desires. A volitive desire is “synonymous with *want*, *wish*, and *would like*, and appears as a *transitive verb* in sentences like ‘I desire to ...’ and ‘I desire ...’” (Davis, 1997, p. 136, emphasis in original). For example, “John would like to apply to Harvard” and “Mary wants intellectual stimulation in a movie” are volitive desires. By contrast, an appetitive desire has “the near synonyms *appetite*, *hungering*, *craving*, *yearning*, *longing*, and *urge*, and appears as a *noun* in sentences like ‘I have a desire to ...’ and ‘I have a desire for ...’ [moreover] objects of appetitive desire are *appealing*, things we *view with pleasure*” (Davis, 1997, p. 136, emphasis in original). For instance, “Silvia has a longing for her birthplace” and “Paul has a craving for sushi” are appetitive

desires. Davis points out that volitive and appetitive desires are logically independent and can exist empirically in distinct ways:

We often want to eat, for social or nutritional reasons, when we have no appetite and view the prospect of eating without pleasure. We desire to eat, but have no desire to. On the other hand we may have a ravenous appetite and find the prospect of eating terribly appealing and yet not want to eat because we are on a diet. (1997, p. 136)

Bagozzi (1992, pp. 183–194) proposed that desires are fundamental psychological events or states (distinct from cognitive, evaluative, and affective reasons for acting) that convert reasons for acting into intentions to act. Such desires have been termed *behavioral desires* or *action desires*. Mele (1995) calls such desires *extrinsic desires* (i.e., desiring to act as a means to an end). Desires also exist as *intrinsic desires* (i.e., desiring something for its own sake or as an end; Mele, 1995). An important form of intrinsic desires is goal desires.

Desires perform three functions. First, they motivate our goal intentions and our behavioral or action intentions (see CONSUMER INTENTIONS). One way they do this is automatically and nonconsciously or nonde-liberatively through what Damasio (1994, pp. 173–174) called the *somatic-marker hypothesis*. That is, prior to conscious processing of pros and cons characteristic of rational decision making, people experience pleasant or unpleasant feelings that highlight options and create either positive or negative biases, which favor or eliminate options from consideration. Such unconscious processes influence or bias a number of antecedents to decision making and indeed can form the basis for certain desires. It is likely that declarative knowledge processed rationally by consumers (with regard to facts, alternative goals and brands, consequences of consumption, and various expectations one has) is influenced by unconscious preference biases residing in the brain and arising from previous emotional experience associated with similar decision problems. Bechara *et al.* (1997) present research showing that such covert processes bias decision making prior to cognitive evaluation and reasoning and without awareness occurring

on the part of decision makers. The authors suggested that the unconscious processes guide or shape behavior, before conscious processing commences, and function to produce better decisions, especially to the extent that learning accumulates as a consequence of previous rewards and punishments, which become stored as nondeclarative dispositional knowledge. It is possible that some desires, especially appetitive ones, develop in this way and become the basis for goal desires and even some behavioral desires.

Now consider a second function of desires. People are often aware of their desires, and desires seem to function consciously in many decision-making settings. This is especially true for volitive desires. It is common for a decision maker to have many reasons for action, some of which might even conflict or constitute reasons for not acting in the very same decision context. In such cases, desires serve to integrate or summarize a decision maker's overall felt urge to act as a function of multiple, mixed reasons for action. Reasons for action are appraised, combined, and transformed into a motivation to act. Whether this happens as a deterministic resultant of competing forces in response to reasons for action, or follows learned rules of weighting and consolidation, remains to be studied. But in the face of multiple reasons for acting and not acting, in which some reasons are determinative whereas others are not, people subjectively experience and express their final felt urge to act.

A third function for desires is to induce an intention; a goal desire incites a goal intention, and a behavioral desire evokes an implementation intention. (see CONSUMER INTENTIONS). Desires harbor energy in an action-tendency or consummatory sense, but without precise direction and without a personal commitment to act. Intentions provide precise direction and personal commitment in this sense. These are the primary differences between desires and intentions. Yet another distinction is that intentions, but not desires, can entail a plan to act, though not all intentions necessarily contain or imply plans. Perugini and Bagozzi (2004) explored additional distinctions between desires and intentions.

Left unchecked, desires tend to influence intentions. This happens for goal intentions as

well as for action or behavioral intentions (see CONSUMER INTENTIONS). An important issue for research is how desires are self-regulated (see Bagozzi, 2006 and SELF-REGULATION). As we become aware of our desires, we may reflect upon them and apply self-evaluative standards. In this regard we may ask ourselves (figuratively or literally) whether we are the sort of person who should have, and act, on these desires. The answer may encompass a decision to cancel, override, or postpone implementation of the desire through intention formation. The decision might be influenced by one's social, moral, or self-conscious emotions (e.g., pride, gratitude, guilt, shame, embarrassment, contempt, disgust, anger), by one's ethics, moral beliefs, or character, by one's personal or social identity, or by one's feelings of empathy, love, or affection for another person implicated by the desire one way or the other. In parallel way, a person might come to question why he/she has no desire for a goal or to act and then embrace such a desire as a function of determinants similar to those mentioned in the aforementioned sentence.

opinion leadership and market mavens

Ronald Earl Goldsmith

SOCIAL COMMUNICATION AND CONSUMER BEHAVIOR

Consumers use information to make shopping and buying decisions. They get some of this information from marketer-dominated sources such as advertisements, salespersons, brochures, packages, web pages, and promotions. Another and perhaps more important source of information comes in the form of social communication (*see* SOCIAL INFLUENCE). This is the influence consumers have on other consumers. Also termed *non-marketer-dominated* sources, the influence of other consumers can be passive, where consumers simply observe others and imitate them, or active, where consumers talk to each other, seeking or offering advice and information as part of everyday life (Weimann, 1994).

This final form of social communication is often termed *word of mouth*. Word of mouth can be incidental, where topics covering products, advertisements, stores, brands, and buying can be part of ordinary conversations. Consumers can also actively seek advice and information from other consumers or they can actively give information. The former describes opinion seeking and the latter opinion leadership. Opinion leaders are consumers who actively transmit information to other consumers either on their own initiative or after information seekers solicit them. Some consumers called *market mavens* are especially involved in the marketplace (*see* CONSUMER INVOLVEMENT). They are knowledgeable and actively influence other consumers. Because opinion leaders and market mavens exert such a powerful influence on sales, marketers are keen to identify them and to persuade them to promote their brands.

OPINION LEADERSHIP

Most opinion leadership takes the form of product category or domain-specific opinion leadership where consumers spread word of mouth about specific types of products, such as clothing, movies, cars, food, and so on (Flynn, Goldsmith, and Eastman, 1996). The

chief antecedent or motivator for opinion leadership is likely involvement, or the interest, enthusiasm, and excitement consumers feel for their favorite categories. Opinion leaders are not only involved in their favorite domains, they are knowledgeable about them, widely exposed to marketer-dominated sources of information, eager to buy new products in the domain (*see* CONSUMER INNOVATIVENESS), and motivated to influence others. Opinion leadership occurs both off-line in the physical world as well as online in cyberspace, especially in SOCIAL NETWORKS where a small number of enthusiastic consumers dominate the flow of information across the network (Iyengar, Van den Bulte, and Valente, 2008).

In addition, some consumers act as general opinion leaders where their influence cuts across several domains (Keller and Berry, 2003). This general type of opinion leadership suggests that some consumers are especially important in the spread of information through social connections. The most thorough examination of this general marketplace behavior occurs in the research stream devoted to market mavenism.

MARKET MAVENS

Market mavens were first described by Feick and Price (1987, p. 85) as: "individuals who have information about many kinds of products, places to shop, and other facets of markets, and initiate discussion with consumers and respond to request from consumers from market information." Since then, researchers have extended the understanding of this phenomenon. Market mavens cannot be especially defined by their demographics, but do thrive in different countries around the world (Chelminski and Coulter, 2007). These consumers pay close attention to ads and brands, they like to shop, they think about shopping and buying, they like to talk to others about ads, stores, products, shopping, and consuming in general. They clip and trade coupons. They know the best places to buy and actively recommend them to their friends. They are aware of and eager to buy new products. They act as general opinion leaders but differ from them through their greater engagement in the marketplace and variety of market-related behaviors.

optimum stimulation level

Jan-Benedict E. M. Steenkamp

THE CONSTRUCT OF OPTIMUM STIMULATION LEVEL

The notion that human behavior is sometimes instigated by the mere desire to attain a satisfactory level of stimulation has figured prominently among psychological theories investigating motivational tendencies as causes of people's actions (Berlyne, 1963; Zuckerman, 1994). People tend to prefer intermediate levels of stimulation, referred to as the *optimal stimulation level (OSL)* in the literature. There are reliable individual differences in the amount of stimulation considered optimal by a given person, which appear to be affected by social learning factors as well as biochemical substances (Zuckerman, 1994).

To attain a satisfactory level of stimulation, a person may engage in exploration of the environment. As stated by Berlyne (1963, p. 288), exploratory behavior is "an end in itself" "with" the sole function of changing the stimulus field." Psychologists have studied exploratory tendencies extensively, and the general finding has been that people with higher OSLs engage in exploratory behaviors to a greater extent than people with lower OSLs (see Zuckerman (1979, 1994) for reviews).

MEASUREMENT. Several self-report measures have been developed to assess OSL, among them the 40-item Arousal Seeking Tendency (AST) scale, and its revised version, the 32-item AST-II scale, the 95-item Change Seeker Index (CSI), the 40-item Sensation Seeking Scale, version V (SSS-V), and the 80-item Novelty Experiencing Scale (NES). Despite the different labels, all scales load on the underlying construct of OSL (Steenkamp and Baumgartner, 1992). AST-I/II, SSS-V, and NES scales specify subfactors, but research has indicated that their factorial structure is generally unstable. Consumer researchers have, therefore, almost invariably used summated scores on the total scale. The reliability of the summated scores on each scale is high.

Steenkamp and Baumgartner (1992) concluded that CSI is the preferred instrument,

based on extensive psychometric and nomological tests. However, with 95 items, CSI is much too long to be of practical use in most research applications. To address this issue, Steenkamp and Baumgartner (1995) developed a 7-item short-form version of the CSI scale. The 7-item scale has better psychometric properties and nomological validity than the original, 95-item scale. These items are listed in Table 1.

RELEVANCE OF OPTIMUM STIMULATION LEVEL TO UNDERSTANDING CONSUMER BEHAVIOR

The consumer behavior literature has been dominated by the information processing paradigm, in which it is assumed that the consumer purposefully solves problems in order to achieve goals. However, since the seminal article by Holbrook and Hirschman (1982), researchers have increasingly recognized that many consumer behaviors are not (solely) purposeful in this sense, but also contain a strong exploratory component. For example, a consumer may not only buy a new product because she/he believes that the product is of better quality (information processing perspective) but also because she/he likes the excitement of trying out something new (exploratory perspective). As such, the exploratory perspective adds to our understanding of consumer behavior.

The fact that psychological research has uncovered that exploratory tendencies are related to a person's characteristic need for stimulation suggests that OSL may be a major determinant of consumer behaviors with strong exploratory elements. Indeed, a growing body of research has shown that OSL is an important factor in explaining a wide variety of consumer behaviors with an exploratory component. Consumers seeking thrills, adventure, disinhibition, new experiences, fantasies, cognitive or sensory stimulation, escape from boredom, and alternation among familiar things have been identified as engaging in exploratory consumer behaviors in order to raise their level of stimulation in life (Baumgartner and Steenkamp, 1996; Celsi, Rose, and Leigh, 1993; Holbrook and Hirschman, 1982; Raju, 1980; Steenkamp and Baumgartner, 1992; Steenkamp

Table 1 Items of CSI short-form scale.

-
1. I like to continue doing the same old things rather than trying new and different things.^a
 2. I like to experience novelty and change in my daily routine.
 3. I like a job that offers change, variety, and travel, even if it involves some danger.
 4. I am continually seeking new ideas and experiences.
 5. I like continually changing activities.
 6. When things get boring, I like to find some new and unfamiliar experience.
 7. I prefer a routine way of life to an unpredictable one full of change.^a
-

and Burgess, 2002; Steenkamp, ter Hofstede, and Wedel, 1999).

High OSLs have a greater preference for emotionally charged stimuli such as fear-arousing ads (Steenkamp, Baumgartner, and Van der Wulp, 1996) and have a greater interest in pursuing fantasies and fun (Holbrook and Hirschman, 1982). They engage more often in information search out of curiosity, generate more curiosity-based thoughts when exposed to ambiguous ads, and experience greater tedium during repeated exposure to the same ad (Baumgartner and Steenkamp, 1996; Steenkamp and Baumgartner, 1992). High OSLs exhibit more variety seeking and have a greater interest in knowing about novel or complex products and brands out of curiosity (Raju, 1980). OSL is related positively to a person's tendency to try out new retail outlets (Mittelstaedt *et al.*, 1976) and to his/her willingness to purchase new products and brands (Baumgartner and Steenkamp, 1996; Gielens and Steenkamp, 2007; Steenkamp and Gielens, 2003). Steenkamp and Burgess (2002) provide evidence that OSL does not only have relevance for understanding behavior of Western consumers but also holds great promise for understanding the behavior of consumers in emerging markets.

CONCLUSION

OSL is firmly grounded in psychological theory and can be measured reliably with self-report measures. OSL is of great relevance for understanding consumer behavior, both in high-income countries and in emerging markets. While it is generally believed that

general personality traits have little explanatory value for consumer behavior, OSL is clearly an exception. Since many consumer behaviors have an exploratory component, the theoretical potential of OSL is substantial. Therefore, consumer researchers are encouraged to include OSL more often in their research design.

marketing and feminism

Elizabeth C. Hirschman

The development of feminist theory in marketing has an uneven history. During the 1990s researchers published some key papers and articles which helped gain a foothold for feminist thought (see e.g., Bristor and Fischer, 1993; Hirschman, 1993; Stern, 1993).

This effort was expanded by a growing set of feminist researchers during the 1990s to incorporate ecofeminism (Dobscha and Ozanne, 2001), gender roles (Penalosa, 1994), gay and lesbian studies (Penalosa, 1996) and critiques of marketing ideology as essentially masculine (Penalosa, 1994). These diverse lines of research were consolidated in an edited volume (Catterall, Maclaran, and Stevens, 2000) which effectively summarized the state of theorization and application of feminism in marketing over the prior decade.

During the past decade, that is, 2001–2010, feminism has been expanded further into marketing areas such as environmentalism (Dobscha and Ozanne, 2001; Scott and Penalosa, 2006), queer studies (Scott and Penalosa, 2006), and critical theory (Maclaran *et al.*, 2008). However, feminist research has not made the advances one would have expected, given its early theoretical potency and intrinsic applicability to a wide set of marketing phenomena. In particular, little attention has been directed toward the economic progress of women in marketing careers or, indeed, within the academy, itself (for an exception, see Penalosa, 2000). For example, women have served as editors of the *Journal of Consumer Research*. However, they have not acted in a similar capacity in the *Journal of Marketing*, *Journal of Marketing Research*, or *Journal of Public Policy and Marketing*.

A portion of this slowdown is likely attributable to the redirecting of research attention toward critical theory, generally, and even more recently toward transformative research agendas on the part of feminist marketing scholars (see e.g., Catterall, Maclaran, and Stevens (2005, 2006)). However, the larger part may be due to a “feminist generational gap.”

The majority of productive feminist scholars in marketing matured as researchers during the

early 1990s, a time period during which feminism played a more active role in academic discourse and public awareness. Over the past decade, while the ranks of women scholars in marketing have doubled, there has been little interest among these newcomers to apply feminist thought in their research agendas. Indeed, many may see little or no need for feminism on either a personal or academic level. Sadly, this viewpoint on their part is mistaken, as there are still ongoing gender discrepancies in salary, promotion, and the larger academic reward structure, as for example, journal editorships.

Further, as Scott (2009); Dolan and Scott (2009) has argued, there are many pressing issues for women in developing countries which tend to be given little attention by feminist researchers in Western Europe and North America. Among these are legal restrictions on women's rights to own property and work outside the home, very insufficient access to health care and education, and restrictions on travel. Recent initiatives to provide basic health care and employment opportunities have the potential to remake the lives of hundreds of millions of women around the world (Scott, 2009). Thus, there remains much important work to be done and a reawakening of interest in the relationship between feminism and marketing would be of great value to the field – and the lives of women – in many ways.

consumer categorization

Barbara Loken

CATEGORIZATION CONSTRUCTS AND DEFINITIONS

A *consumer category* is “a set of products, services, brands, or other marketing entities, states, or events that appear to the consumer, related in some way” (Loken, Barsalou, and Joiner, 2008). The types of categories studied in marketing include *taxonomic* categories such as *product* categories (e.g., “snack foods”) and *brand* categories (e.g., “Coach”). Consumers also have *goal-derived* categories, which focus on a desired outcome such as “ways to chat with my friends”, and might include telephone, Facebook, and email as category members (Ratneshwar *et al.*, 2001).

Category members have *graded structure*; they vary probabilistically in how representative or *prototypical* they are of the category. For example, Coach handbags are more typical and a better example of the Coach brand category than Coach sunglasses. Prototypical category members tend to be better liked, have more ideal or favorable category features, and are encountered more frequently, than atypical members (Loken and Ward, 1990; Veryzer and Hutchinson 1998; Viswanathan and Childers, 1999).

CATEGORY STABILITY AND FLEXIBILITY

Research on consumer categories yields several conclusions (see Loken, Barsalou, and Joiner, 2008, for a review). First, categories are both *stable* and *flexible*. A consumer’s concept of Crest as a prototypical toothpaste brand stays relatively stable over time, and consumers would generally agree that toothpaste (rather than “dental hygiene”) is a “*basic level*” of categorization. Category membership and representation are also flexible, shifting with the context. For example, the prototypical beverages “at a football game” are different from those “at an opera intermission”. Consumers’ goals often motivate their categorizations (Ratneshwar *et al.*, 2001). The goal-relevant

attribute of “sophistication” may drive category membership of beverages at the opera but not at football games. Category experts tend to show more category flexibility and greater use of subcategories than novices (Cowley and Mitchell, 2003), and consumers categorize differently depending on their cultural self-view as either Eastern or Western (Jain, Desai, and Mao, 2007).

Brand categories (e.g., Kashi products) are flexible in that atypical extensions (e.g., Kashi candy) “fit” the category better under some conditions than others. When consumers are in a good mood, or seeking variety or risk, they rate moderately atypical brand extensions as better category members. People accept more moderately atypical category members when a brand category is broad (e.g., Healthy Choice) than narrow (e.g., Campbell’s). However, extremely atypical category extensions (e.g., Kashi electronics) are viewed as atypical regardless of the context. *Assimilation-contrast* processes also can explain flexibility of category members (cf. Schwarz and Bless, 2007).

CATEGORY INFERENCES

A second conclusion is that consumers use category information to make inferences about new category members. Consumers transfer beliefs and attitudes about a brand (e.g., the Coach brand is associated with “leather” and “designer status”) to a new brand extension (e.g., a new Coach pink leather belt) when the brand extension is viewed as similar to, or a good fit for, the brand.

Third, consumers use information about new category members to make inferences and judgments about the overall category. A new BMW hybrid might increase consumers’ beliefs that BMWs have “good gas mileage” or decrease beliefs that BMWs have “excellent performance”. Failed extensions in near product categories and successful extensions in far product categories affect brands, particularly when other information is inaccessible.

SUBCATEGORIZATIONS

Fourth, consumers use *subtypes* or subgroupings of categories to more finely differentiate a

category. For example, Apple *subbrands* might include MP3 players (iPod), handheld computers (iPhone), laptop computers (iMac), and musical software (iTunes). Marketers use subbrands to call attention to unique or innovative features, and these subbrands sometimes develop into strong categories of their own. When a subbrand has multiple members (e.g., multiple electric cars in the vehicle category), consumers are more likely to position a new product within this subbrand (Lajos *et al.*, 2009).

Fifth, consumers enjoy products more and *satiates* less quickly when they categorize at a lower or *subordinate* level (Redden, 2008). For example, enjoyment of jelly beans continues longer when the candy is categorized specifically (e.g., orange, cherry) than generally (e.g., jelly bean). Subcategorizations focus people's attention on differences between category members. Having multiple subcategories (e.g., on a store shelf) signals variety, which can increase consumers' sense of self-determination and overall satisfaction (Mogilner, Rudnick, and Eyengar, 2008) but can also bias choices (Fox, Ratner, and Lieb, 2005).

ACKNOWLEDGMENT

Thanks to Joe Redden for comments and suggestions on an earlier draft.

environmental consumer behavior

John A. McCarty, L. J. Shrum, and Tina M. Lowrey

Environmental consumer behavior, or more commonly, “green” consumer behavior, refers to a general class of behaviors (and their underlying processes) involved in purchasing, using, and disposing of products and services with the intention of improving the environment. A variety of activities can be considered under this umbrella. Probably the two most prominent ones are the extent to which consumers buy products that are environmentally friendly and the extent to which they dispose of product waste in an environmentally responsible manner. From a perspective of environmental activities, these two are related in that the disposal of waste (e.g., recycling of paper) provides some of the materials for the production of environmentally friendly products. Thus, in the materials life cycle (*see* FAMILY LIFE CYCLE) (Shrum, Lowrey, and McCarty, 1996), from the manufacturing of products and their packaging through consumer use to the disposal or recycling of the products and/or packaging, these two consumer actions (green buying and recycling) are the behaviors by which consumers can have the greatest potential impact on the environment.

Although a variety of polls over the last couple of decades show that consumers desire to become more “green” and are concerned about the environment, such findings are not always consistent with what consumers do (*see* ATTITUDE-BEHAVIOR CONSISTENCY), particularly in the area of buying green. For example, a 2007 global survey by McKinsey & Company (Bonini and Oppenheim, 2008) showed that 87% of the respondents indicated that they were concerned about the environment; however, only 33% reported that they bought or would buy green products. Thus, engaging in environmentally responsible behaviors, like other behaviors, is only partially determined by individuals’ values, ATTITUDES, and intentions. There are a number of other factors that may facilitate or impede green behavior. In particular, polls typically show that consumers’ reluctance

to buy green relates to several key impediments: eco-friendly products are perceived as more expensive than other product offerings; eco-friendly products are perceived as less effective than other alternatives; and consumers are often skeptical of the claims made by environmentally friendly brands.

Besides buying green products, the other major way that consumers can act on their concern for the environment is to recycle the waste from the products they purchase. Like buying green, however, concern for the environment is but one of the factors that relate to the extent to which consumers will recycle materials such as paper, glass, and plastic. In terms of facilitating or inhibiting factors, the perceived convenience of recycling appears to facilitate the extent to which consumers recycle (McCarty and Shrum, 2001). Municipalities and organizations have caught on to this, and over the years there have been increased efforts to ease the burden on consumers to recycle. From the times when consumers had to take recyclables to special locations or bring recyclables to recycling drives at specific times, most cities now provide containers for recycling materials that are picked up at regular intervals.

Although making recycling more convenient increases recycling rates, it is still critical for consumers to believe that it is important. In fact, research has shown that consumers who feel that recycling is important tend to perceive it as less inconvenient, compared with those who do not feel it is important (McCarty and Shrum, 2001). The belief that recycling is important is driven, to some degree, by a variety of social and personality variables, such as values and attitudes; thus, these individual difference variables are critical to the success of consumer recycling.

Researchers have searched for antecedents of consumers’ beliefs about the importance of recycling and pro-environmental behavior more generally. It appears that psychographic and personality variables show a stronger relationship with recycling attitudes than do demographic variables such as age and income (Straughan and Roberts, 1999). In particular, variables that are related to recycling include materialism (the extent to which one attaches importance to possessions), collectivism (the

2 environmental consumer behavior

extent to which one believes in the importance of the group over the individual), and locus of control (the extent to which people believe that they control their lives rather than that they are controlled by external forces). Those who are more materialistic tend to have more negative attitudes toward the environment than do those who are less materialistic (Kilbourne and Pickett, 2006). Those who are more collectivistic tend to believe that recycling is more important than do those who are less collectivistic (McCarty and Shrum, 2001). People with an internal locus of control tend to believe that recycling is more important than do those who have an external locus of control (McCarty and Shrum, 2001). Presumably, those with an internal locus believe that their environmental efforts will have an impact and thus believe that such activities can be important.

habit in consumer behavior

Leona Tam

A habit is a behavioral disposition in which past responses are triggered directly by associated context cues. Consumer habits can be triggered by a wide array of cues in purchase and consumption contexts, including physical settings, presence of others, mood, time of day, and actions that immediately precede a habitual response. Thus, the theater environment may trigger popcorn consumption, or a visit from family around dinnertime might trigger a trip to Olive Garden.

How is habit formed? Consumer habits are formed when purchases and consumptions are repeated under similar circumstances. Such repetitions strengthen the cognitive associations between consumer responses and purchase and consumption contexts. When habits have formed, perception of the familiar cues activates a representation of the practiced, habitual response in memory. Given this reliance on cues, consumer habits are maintained when cues in the purchase and consumption contexts remain stable. Habits change when the cues are altered or when consumers are motivated and able to inhibit their automatic responses to the cues.

Even when consumers intend to try new brands and thereby change their established brand habits, they may continue to repeat past purchase and consumption activities when those responses are cued automatically by stable features of the environment. Because habits are automatically brought to mind in the appropriate circumstances, they tend to be repeated unless consumers are willing and able to exert effortful control to inhibit the activated response and to select a new one, or when the circumstances triggering habitual responses are changed.

Owing to the automaticity in consumer habits, consumers' habits do not necessarily change through altering behavioral intentions. How can consumers change their habits? One possibility is to take advantage of the *habit discontinuity effect*, or the disruption in habits that naturally occurs when people change life contexts. Change in performance contexts can shift consumer habits out of an automatic mode so that purchase

and consumption become more deliberate and guided by consumer intentions. With changes in performance contexts, the habitual behavior may no longer be automatically brought to mind, and people may be released to act in ways consistent with their intentions and preferences. Marketers could target interventions to change consumers' habits to use competing brands for times at which consumers undergo naturally occurring changes in habit contexts, for example, when consumers relocate and may not have access to old retail outlets and associated brands. Retailers like Home Depot and Bed Bath & Beyond offer discounts as incentives to encourage patronage of consumers who have recently relocated. This strategy should effectively attract habitual consumers of competitor's brands whose habits are disrupted because of relocation.

Habitual consumers can also undertake to change their response to context cues, but not without sufficient regulatory strength to inhibit habits. In the implication of the willpower required for habit inhibition, marketers may wish to set up promotions and other sales events so that consumers repeatedly purchase and use their brand in ways that foster habit formation. Once formed, habits persist because they require willpower effort to inhibit. Illustrating such a promotion, a consumer recently received in the mail six \$10 coupons for a new grocery store. Each coupon was valid for one week, and the coupon promotion was held over a period of six consecutive weeks. In order to use the coupons, she went to that grocery store every week, despite that there was another store she preferred. After six weeks, when all the coupons were used, she found herself going automatically to the new grocery store for the next shopping trip. She had formed a habit to frequent the new store, and, especially after a depleting day at work, it was easier to follow that habit than to inhibit it and choose another store.

Consumer habits are sometimes referred to as low involvement decision making, given the lack of effortful processing in consumer habit performance. However, consumers often repeat important purchases and consumptions and thus form habits. Health conscious consumers purposefully go to a salad bar for lunch on weekdays and are very likely going to form

2 habit in consumer behavior

a strong habit to do so after a few weeks of repetitions. Therefore, consumer habits are not limited to products of low involvement to consumers. The critical distinction between habits and brand loyalty for marketers lies in whether repeated purchase and consumption reflect the repetition of a particular response (habits) or whether they reflect an evaluative disposition that can guide repetition of a variety of brand responses (loyalty). Thus, for marketers, managing habitual customers requires different programs than those that are typically used to manage loyalty. Managing habits involves changing or maintaining the cue or the response to a cue, while managing loyalty involves improving or changing consumers' brand evaluation or favorability.

childhood socialization and intergenerational influences

Elizabeth S. Moore

“To what extent do family influences experienced during childhood continue to exert influence on our behavior as adults?” This question frames the study of *intergenerational influence*, which is defined as the transmission of information, resources, and beliefs from one family generation to the next. Given the prolonged nature of childhood learning, the fact that some beliefs and attitudes formed within the household persist into adulthood comes as no surprise. It is the *nature* of these influences that is of interest, a topic rooted in socialization theory, and a long-standing area of inquiry in the social sciences (Macoby, 2007).

Socialization is the process through which individuals develop skills, beliefs, and behaviors needed to function successfully in society. It is a primary mechanism by which culture sustains itself. It also helps individuals to develop their personal identities, and assume new roles as they mature. Although socialization is a life-long process, childhood and adolescence are particularly crucial periods of this process.

The family, schools, mass media, religious institutions, and peers contribute in important ways to the socialization process. However, the family is the first and typically most powerful socialization agent, with parents and other family members serving as channels of information, sources of social pressure, and support. Socialization is a bidirectional process with parents and children influencing one another.

Consumer socialization, defined as “processes by which young people acquire the skills, knowledge and attitudes relevant to their functioning in the marketplace” is one aspect of the broader socialization process (Ward, 1974). Published research provides insight into the development of children’s decision-making skills and marketing knowledge, particularly advertising (see John’s, 1999 review). It also helps to understand parent–child interaction in household purchase decisions and impacts of parenting style (Carlson and Grossbart, 1988).

Intergenerational consumer research emerged in the 1970s. Since then scholars have shown

that these effects are significant, interesting, and potentially important in the marketplace. Early research focused on consumer buying styles. Hill’s (1970) longitudinal study showed, for example, that financial planning skills transfer across generations, particularly in families that are poor planners. Parent–child commonalities have also been discovered for choice heuristics, marketplace beliefs, and innovativeness. Interestingly, Cotte and Wood (2004) found that consumer innovativeness is affected by both parents and siblings, but parents are more influential.

Researchers have also examined the transmission of brand and product preferences, outcomes with direct strategic implications. For example, the public versus private nature of consumption for shopping goods may impact family influence levels (Childers and Rao, 1992). Intergenerational impacts are also a source of brand equity for packaged goods, but only for some brands, thus posing strategic challenges for particular marketers (Moore, Wilkie, and Lutz, 2002). These effects are multidimensional (impacting usage, consideration, and preference) and difficult to isolate analytically. Further, many factors are at work in adulthood to sustain or disrupt them.

Current knowledge of intergenerational influences in consumer research is grounded in a relatively small research base. Primary emphasis has been on documenting effects and the forms these take (Moore and Wilkie, 2005). Intriguing challenges lie ahead in the development of new measurement approaches, in understanding the determinants of intergenerational influences, and variation across families.

consumer brand loyalty

Richard L. Oliver

INTRODUCTION

This article describes the general field of consumer (customer) loyalty as it is currently conceptualized. Whereas the field has been approached from many perspectives, the most common appearing in the area of repeat purchasing, more psychologically based approaches are now coming into fruition.

Here, the underlying mechanisms of how consumers manifest, consciously or subconsciously, their loyalty mind-set are explored so that greater loyalty development and switching avoidance can be engendered. Readers interested in more detail and elaboration, including discussion of topics not covered here, should consult the author's original works (Oliver, 1997; Oliver, 2010) and an earlier conceptual article on loyalty determinants (Oliver, 1999).

CONSUMER BRAND LOYALTY

Oliver (1997, p. 392), had proposed the following definition as being consistent with conceptual and empirical evidence:

Customer loyalty is a deeply held commitment to rebuy or repatronize a preferred product or service consistently in the future, *despite* situational influences and marketing efforts having the potential to cause switching behavior (italics in original).

To put this consumer display of loyalty in perspective, an elaboration of the stages and their vulnerabilities, which will address the “despite” clause, brings what is known of loyalty to the recognition of a social extension, discussed later in this article.

Loyalty phases. The framework used here follows the cognition-affect-conation historical pattern of attitude engagement (Taylor, Hunter and Longfellow, 2006), but differs in the sense that consumers can become “loyal” or “locked” at each loyalty phase. Specifically, consumers are thought to first become loyal in a cognitive sense, then later in an affective sense, still later in a conative manner, and finally in a behavioral manner, described as *action inertia*.

Cognitive loyalty. In this first loyalty phase, the brand attribute information available to the consumer suggests that one brand is preferable to its alternatives. This stage is referred to as *cognitive* loyalty or loyalty based on brand belief only. Cognition can be based on prior or vicarious knowledge and recent experience-based information. Loyalty at this phase is directed toward the brand because of this “information” (attribute performance levels). This consumer state, however, is of a very shallow nature. If the transaction is routine, so that satisfaction (*see* CUSTOMER SATISFACTION) is not processed (e.g., trash pickup, utility provision), the reaches of loyalty are no deeper than mere performance, and “performance-only” models apply here. *If* satisfaction is processed, it becomes part of the consumer's experience and begins to take on affective overtones.

Affective loyalty. At the second phase of loyalty development, the emergence of a liking or attitude toward the brand is required on the basis of cumulatively satisfying usage occasions. Commitment at this phase is referred to as *affective* loyalty (*see* EMOTION) and is encoded in the consumer's mind as cognition *and* affect. Whereas cognition is directly subject to counter-argumentation, affect is not as easily dislodged. Here, the brand loyalty exhibited is directed at the degree of affect for the brand. Like cognitive loyalty, however, this form of loyalty remains subject to switching as evidenced by the data showing that large percentages of brand defectors claim to have been previously satisfied with their brand, a phenomenon known as the *satisfaction trap* (Reichheld and Teal, 1996). Thus, it would be desirable if consumers were loyal at a deeper level of commitment.

Conative loyalty. The next phase of loyalty development is the *conative* stage, as influenced by repeated episodes of positive affect toward the brand. *Conation*, by its definition, implies a brand-specific commitment to repurchase. Conative loyalty, then, is a loyalty state containing what at first appears to be the deeply held commitment to buy, noted in the loyalty definition. However, this commitment is to one's intention to rebuy (*see* CONSUMER INTENTIONS) the brand and is more akin to

motivation. In effect, the consumer desires to repurchase, but like any “good intention,” this desire may be an anticipated but unrealized action. At this point, commitment is an additional overlay to the prior cognitive and affective bases of loyalty.

Action loyalty. The study of the mechanism by which intentions are converted to actions is referred to as *action control* (Kuhl and Beckmann, 1985). In the action control sequence, the motivated intention in the previous loyalty state is transformed into *readiness to act*. The action control paradigm proposes that this is accompanied by an additional *desire to overcome obstacles* that might prevent the action. Action is seen as a necessary result of engaging both of these states. If this engagement is repeated, an “action inertia” develops, thereby facilitating repurchase.

Readers will note the correspondence between the two action control constructs, readiness to act and the overcoming of obstacles, to the loyalty definition presented earlier. Readiness to act is analogous to the “deeply held commitment to rebuy or repatronize a preferred product/service consistently in the future,” while “overcoming obstacles” is analogous to rebuying “despite situational influences and marketing efforts having the potential to cause switching behavior.” Thus, completing the earlier cognitive-affective-conative frameworks with a fourth, or action phase, brings the attitude-based loyalty model to the “behavior” of interest – the action state of inertial rebuying (see ATTITUDE-BEHAVIOR CONSISTENCY).

OBSTACLES TO LOYALTY: SWITCHING INCENTIVES

It may have occurred to the reader that true loyalty is, in some sense, fragile as long as alternatives are available. Competitors could (and do) take advantage of this position, engaging consumers via persuasive messages and incentives with the purpose of attempting to lure them away from their preferred offering. These verbal and physical enticements are the obstacles that brand or service loyalists must overcome. As may be evident at this point, the easiest form of loyalty to break down is the cognitive variety;

the most difficult is the action state. Thus, the cognitive-to-action loyalty sequence brings the analysis closer to the emergence of “full” loyalty, but still may fail as each phase is subject to attack, as follows.

Cognitive loyalty. In the case of cognitive loyalty, it has been noted that this level of loyalty is based on purely functional characteristics, primarily costs and benefits, and is thus subject to functional shortfalls. For example, in many areas, it has been shown that deteriorating performance, apart from dissatisfaction, is a strong enhancement to switch. Thus, cognitive loyalty is actually “phantom loyalty,” as it is directed to benefits and costs and not to the brand. Costs (including prices), in particular, are a major component of brand switching at the cognitive level.

Before moving to affective loyalty, it is necessary to address the commonly observed breakdown in the satisfaction-loyalty link (i.e., the “trap”). Two situations are of note. The first is apparent disloyalty (switching) in the face of satisfaction and the second is apparent loyalty when encountering very low levels of satisfaction (dissatisfaction). The first is easily explained by cognitive loyalty that is overcome by attractive alternatives, as noted. The second is also easily explained by a phenomenon that has come to be known as *cognitive lock-in* (Büschken, 2004).

Lock-in can be achieved via many tactics. The most obvious is through a supply monopoly such as video game cartridges. At the interpersonal level, consumers have been known to become loyal to particular provider employees (e.g., salespeople). It is also known that normal consumer failings such as the sunk cost phenomenon and ordinary consumer learning are strong motivators to stay with an otherwise dissatisfying provider. Working in parallel with these influences is the notion of simple fear of the unknown. These are all reasons for firms to “ensnare” consumers so that they are held through “captive loyalty.”

Affective loyalty. Barring lock-in, affective loyalty can become susceptible to dissatisfaction with the cognitive elements of a purchase, thereby inducing attitudinal shifts. A concurrent effect of dissatisfaction is the

increased attractiveness of alternatives, as noted. Thus, affective loyalty is first subject to the deterioration of its cognitive base, causing dissatisfaction, which has deleterious effects on the strength of one's attitude toward a brand, and hence, affective loyalty. It is also possible for competitive communications to use imagery and association to enhance the desirability of alternative brands while degrading that of the present brand.

Conative loyalty. Although conative loyalty brings the consumer to a stronger level of loyalty commitment, it has its vulnerabilities nonetheless. Although a consumer at this phase can weather some small number of dissatisfactory episodes, the consumer's motivation to remain committed can be "worn down" by barrages of competitive messages, particularly if they enhance the perceived severity of experienced dissatisfaction, a phenomenon called *prejudice*.

This occurs, not only via marketing communications, but also through social pressure from one's environment. In fact, it has been shown that social norms vastly dominate satisfaction (dissatisfaction) in the prediction of switching intentions (Roos, 1999). Additionally, competitive product trial, via samples, coupons, or point-of-purchase promotions, may be particularly effective here as the consumer has only committed to the brand, but has not committed to avoiding trial of new offerings. Thus, the conatively loyal consumer has not developed the "resolve" to intentionally avoid consideration of competitive brands.

At this juncture and perhaps before action loyalty manifests itself, the firm has achieved *product superiority*. Here, the firm has engendered enhanced liking—even an established preference—for its brand because of quality (information) and continued ability to satisfy. Additionally, the consumer is committed to its repurchase in the future. But, the consumer has not reached the state of resistance, resilience, and the overcoming of obstacles and adversity necessary for lasting loyalty to emerge.

Action loyalty and the beginning of fortitude. When reaching the action phase of brand attachment, however, the consumer has generated both the focused desire to rebuy a

brand and only that brand, and has also acquired the skills necessary to overcome threats and obstacles to this quest. This consumer would be expected to routinely "tune out" competitive messages, to engage in effortful search for the favored brand, and to possibly even shun the trial of competitive brands. Marketers with action-loyal segments need not expend great sums on retention as, theoretically, their consumers would be governed by "inertial" repurchasing. Aside from deteriorating performance, a potential switching inducer at all stages, only insurmountable unavailability would cause this consumer to try another brand.

With the emergence of the action phase, it appears that the formula for loyalty has been largely crafted; later, this state will be referred to as *consumer fortitude*. It is intended that the action-loyal consumer has a deep commitment to repurchase, so much so that such behavior may be guiding itself in some habituated manner. But habituation is not the loyalty of interest. Rather, the quest is for a version of loyalty fitting the description of devotion "against all odds." When found, the state of consumer fortitude is achieved whereby the consumer fervently desires the consumable in a prohibitive, exclusive relationship. This should be a natural occurrence experienced by the consumer and not one created by the marketer.

It is to be borne in mind, however, that it is the province of competition to gain the consumer's attention so as to hear its communications. One major tactic by which this is accomplished, common in one or another way in all loyalty phases, is the creation of dissatisfaction with the current brand. In fact, the role of satisfaction in loyalty formation and defection can now be more fully specified. In the same way that satisfaction is a building block for loyalty, primarily at the affective loyalty stage, dissatisfaction is its Achilles tendon—for it is here that the competition can strike through the creation or facilitation of dissatisfaction at every stage.

Interpersonal loyalty: additional effects in services. Historically, discussion of loyalty effects has focused largely within the context of product marketing. With the possible exception of fan clubs, industries having a large service component were still thought to be governed by

loyalty to the core deliverable. Thus, Starbucks' loyalty is to its product and business model and not to its baristas (service providers). With recognition of the strong interpersonal component of services, loyalty now takes on additional dimensions of a much more binding and even overriding nature. Little research had been available in this new area, save for a small number of sources. This oversight has reversed itself with a number of insights beyond that of the more generic topic of service delivery, primarily with regard to service contact personnel (e.g., Price and Arnould, 1999).

Loyalty programs. We now discuss the emergence of *loyalty programs* that have sprung up since the time of early grocery store promotions. The issue now is that of program-based repetitive purchasing and its link to the mind-set of "true loyalty." One question that must be answered, then, is that of the role of mechanical incentives or rewards in loyalty apart from habit formation, but including inertial states that tend to persist until their exuberance wears off. It is not clear that loyalty programs are quite so "malleable."

The evidence for the success of such programs can be assessed along the four stages of progression. Do purchasing rewards pass the test of cognitive through action sequencing with the attendant behavioral building blocks? The answer given here is "no." Can reward programs be made to provide sufficient structure so that the consumer can become loyal to something such as loyalty to the program and loyalty to the behavior of pursuing its rewards? Possibly "yes." The interesting aspect of this analysis is that insights may be gained into the pursuit of "true" consumer loyalty.

Cognition in loyalty programs. Most rewards programs are based on lock-in principles. Consumers are given participation points that accumulate over time. Programs that give immediate rewards without long-term implications (such as discounts) do little other than condition the consumer to expect future discounts. Moreover, the reward must have value in and of itself or must add value to the basic consumable. Carnival prizes, for example, are too fleeting a reward to the consumer to

have lasting value. In contrast, higher order values (e.g., attainment) do have lasting value either in terms of self-esteem or social approval. Thus, card levels (silver, gold, platinum) or club achievement identification (million dollar, million mile) may work. Tangibles (upgrades, free flights) work for the moment and are good future "carrots." But few of these have lasting implications for the firm.

Loyalty to the prize simply does not engender loyalty to the firm. The firm becomes an instrument, an enabler. Sports is a good example of the many forms of "loyalty to," and an industry that is now in the early throes of programmatic "loyalty." What is the object of the loyalty target? Is it the sport itself, the statistics (including win/loss), team identity, local spirit, the crowd (fans), becoming one of the fans, the camaraderie, or the new incentives that teams are deploying, including preferred seating, among others. And one should not forget the entertainment venue of music, one of the most addictive pursuits due to its biological origin.

Now, if sports and music need some level of minimal incentives, tangible or not, what of truly mundane consumables such as air travel? And what of ordinary everyday purchasing where credit card programs hold sway? The essential value of a reward is similar to all valued consumables. As promotions, they should take on the characteristic of a desired, wanted, or needed item. But simple wanting satisfies only at the cognitive level. Loyalty "icons" must give pleasure in anticipation, in receipt, in use, in ownership, and in further desire. If rewards are viewed as a collection or accumulation, this in and of itself must be of value.

Affect in loyalty programs. This discussion would be incomplete if the next level of affective loyalty were omitted. Does a program enhance the liking one expresses toward the firm? This is where loyalty programs begin to falter. Unless the program rewards can transfer the pleasure of the reward to the pleasure of consuming the sponsor's deliverable, the program becomes available to any competitor. And what if the program becomes the product? When consumers begin buying Crackerjacks for the prizes and discard the product, the product becomes the prize, of little essential value. People begin taking

flights for the next flight they will obtain or to complete the requirements for a free flight of even greater value or to stave off expiration.

The next two phases, conative and action loyalty, remain as goals, but are easily hidden or mimicked. In some sense then, the loyalty progression bifurcates at affective loyalty into a true psychological progression where the stages are in synchrony or into a false appearance of loyalty where consumers go through the motion of being committed and then repeat-purchase. At this point, without a psychological measurement metric, the mechanical and psychological loyalty patterns appear identical. From the firm's perspective, it won't be known which-is-which until true loyalty is allowed to emerge. This can be observed with either of any of a variety of "acid tests" such as termination of the program, comparison to a control market without the program, or lack of defections to competitors with equal or better programs.

The data are universally discouraging with a small number of exceptions (e.g., Dowling and Uncles, 1997). What is clear is that programs increase purchasing in the classic carrot and stick fashion. What is not clear is whether revenues net of the additional costs are profitable and these data are not available except anecdotally. It is also clear that heavy current purchasers are most favorably affected and benefit at the costs of less frequent purchasers. Besides, strategically, programs are necessitated, and costs incurred, when faced with close competitors with programs.

CONSUMPTION COMMUNITIES

Three new perspectives on customer loyalty are proposed, stated as questions: (i) Can the consumer elect to be self-isolated from alternative consumable overtures so that competitive information is blocked or screened? (ii) Can the consumer be socially integrated in an exclusive environment that envelopes and directs the consumer's choices in a satisfying way? (iii) Can the consumer effect a self-identity that corresponds only to selected brand(s) *within* the environment? These issues speak to the "community" of loyalty (*see* BRAND COMMUNITY),

singularly in the case of self-isolation, communally in the case of the environment, and both in the case of a preclusive lifestyle.

Dimensions of the framework. Picture a 2×2 table representing the dimensions on which these new issues are based. The vertical dimension reflects the degree of "individual fortitude," or the degree to which the consumer fights off competitive overtures based on his/her allegiance to the brand and not on marketer-generated "information." Despite an artificial break in this continuum into high (top row) and low (bottom row) categories, it is acknowledged that loyalty commitment develops with the advancement of stages in the four-phase model. At the lowest levels of fortitude, the consumer has only brand-related information. At the highest levels of fortitude, the consumer has developed the action inertia discussed previously, and has *also* developed a fierce defense against competitive encroachment that approaches "blind faith."

The horizontal dimension of the table would illustrate low and high phases of community and social support (McMillan, 1996). Here, the community provides the impetus to remain loyal either because it is enticing in a passive sense or because it proactively promotes loyalty. This dimension is crossed with that of individual fortitude so that the high-high cell contains the apex of loyalty and the low-low cell the weakest case of more vulnerable "loyalty," basic product superiority.

Product superiority, the weakest form of loyalty in this new framework, has already been discussed in cognitive, affective, conative, and action terms. This reflects the traditional view of loyalty as resulting from high quality and/or product superiority, both of which are believed to generate a strong sense of brand-directed preference. At some point in the cognitive-affective-conative-action chain, the consumer will cross the threshold from "low" consumer fortitude to "high," largely on the basis of the degree of immunization against competition that may have developed. The perspective taken here, however, provides further conceptual content in the high-fortitude (and low-social support) quadrant. In addition to the consumer's desire to rebuy on the basis

of superiority, this framework suggests that he or she will also wish to rebuy based on determination or “determined self-isolation,” that is, the consumer desires an exclusive relation with the brand and does not wish to be “courted” by other suitors.

The low-fortitude, high-social-support quadrant represents “village envelopment,” in that it is analogous to the ever-popular concept of “it takes a village.” Here, the consumer is sheltered from outside influences, nurtured in the use of selected and protected brands, and provided integrated and routinely updated consumption systems. The common computer platform and networking environment supported by most businesses is an example of this concept. The distinguishing feature here is that the consumer is a passive acceptor of the brand environment.

Lastly, the high-high quadrant, referred to as *immersed self-identity*, contains the combined influences of fortitude and social support. Here, the consumer has intentionally targeted (or has been targeted by) the social environment because it is consistent with and supports the self-concept. In effect, the consumer “immerses” his or her self-identity in the social system of which the brand is a part. This is a synergistic situation and is self-sustaining. The consumer fervently desires the product or service association, affiliates with the social setting knowing that it will be supportive of this association, and, at the limiting extreme is rewarded by the social system for his or her patronage. Religious institutions are good exemplars of this situation, although other secular social settings are equally illustrative such as fan clubs and alumni organizations.

It should be noted that the defining characteristics of these new perspectives are not directly under the control of management, but can be facilitated by it. They go beyond the cognitive-affective-conative-action sequence, because they transcend it. They tap into the socioemotional side of loyal consumption and closely access its “meaning,” as discussed next.

Self-isolation as a sustainer of loyalty. Crossing the threshold from a belief in product superiority to brand-directed determinism and personal fortitude is a somewhat nebulous process. The transition mechanism is not well understood,

even for areas of life where determinism is frequently observed (e.g., romance, religion, politics). One potential threshold transition phase is that of attachment. Attachment is something more than satisfaction as it requires states of satisfaction reinforcements over time until the “glue is set.” This is an apt description since glue, being a chemical/mechanical adhesive, has resilience until the breaking strength is breached. Brand attachments, particularly those of “human brands,” are not necessarily monogamous, can withstand bouts of dissatisfaction, and display commitment without being “ultimate.” Still, this consumer may very likely be immune from competitive overtures, is unlikely to be swayed from determined repurchasing, may defend the brand fiercely, and would most probably promote the brand to others.

The social organization: the village. In its pure form, the village is a social alliance whereby the primary motivation to become loyal on the part of each consumer is to be one with the group and the primary motivation of the group overseers is to please their constituency. In this situation, the consumer becomes a (willing) participant because of the attention provided by its members. In the limiting case, the product/service is not the “consumable.” Rather, it is the camaraderie provided by the social organization. Good examples of this are the numerous varieties of clubs including internet communities of all types.

This concept goes by many names in its various literatures, but is perhaps best exemplified as the aforementioned *consumption community*, on the basis of the widely observed notion that individuals feel a sense of community when they share the same consumption behaviors. More to the point, when they espouse and own the same brand, these groupings are known as *brand communities* (Muniz and O’Guinn, 2001). Note that the previous “club” examples are somewhat weaker forms of the social collective envisioned here as they largely assume only that the mere knowledge of shared consumption is sufficient to generate a consumption community. Thus, it appears that the social dimension of the proposed framework, much like the fortitude dimension, is a continuum and some of the

examples given “drift” to either the weaker or stronger side.

Individual and social integration: fully bonded loyalty. The final, high-high quadrant in the table encompasses a blend of personal identity with the cultural milieu surrounding the consumable. This situation is distinguished from the previous example of the village because, in the present case, the cultural/social environment may assume a passive or stationary, although enticing, role. Here, the consumer is drawn to the consumable environment as opposed to the situation where the environment defines consumption for the consumer, although this does occur. The main distinguishing feature of this cell is that the consumer finds a “natural match” with both the consumable and its environment.

This is a particularly healthy situation for the firm as the product/service is inextricably embedded within some portion of the consumer’s psyche as well as his/her lifestyle. The consumable is now part and parcel with one’s self-identity and with his/her social identity, that is, the individual cannot conceive of him/herself as whole without it. At the extreme, the object is present intensionally and extensionally. Here, the consumer would say that the object is “part of me” and that it is an “extension of me.” He or she lives it. Strong examples include sects with religious overtones and cults, although consumables in the more ordinary consumption domain are clearly candidates. Common examples include products, services, and even images supported by fans with various levels of group identification. Typically, the identity of the consumer is not known to the team, artist, and so on. The allure of the larger consumption icon is sufficient to “hold” the consumer to the loyalty state.

This concludes the discussion of loyalty influences beyond the cognitive-to-action framework. A consumer’s willingness to rebuy or repatronize cannot reach ultimate extremes until she/he is willing to adore and commit unflinchingly to a product/service. Beyond this, the necessary additional adhesion stems from the social bonding of a consumption community and the synergy between the two. In essence, the consumer wants to be loyal, the social organization wants him/her to be loyal and, as a

result, the two may become symbiotic. The role of satisfaction in loyalty formation, which has not been discussed in this section, is addressed next.

What is the relation between satisfaction and loyalty? In Oliver (1999), a number of plausible relations were suggested linking satisfaction and loyalty. The appropriateness of these in light of the evidence offered is now discussed. The first, suggesting that satisfaction and loyalty are two manifestations of the same concept, is easily dismissed. From the many avenues of discourse presented and the definition of loyalty, it should be clear that the two concepts are distinctly separate. Satisfaction is a fairly temporal postusage state for one-time consumption or a repeatedly experienced state for ongoing consumption that reflects how the product or service fulfilled its purpose. Thus, satisfaction is *delivered* to the consumer. Loyalty, in contrast, is an *attained* state of enduring preference to the point of determined defense.

A second suggests that satisfaction is an essential ingredient for the emergence of loyalty, a third only that it is necessary, and another that there is an ambiguous overlap across the two. There is merit to these perspectives as no perspective discussed here entertains loyalty development without early or concurrent satisfying episodes. While it may be that satisfaction is not a core element of loyalty, particularly after loyalty has set, it is difficult to entertain loyalty development without satisfaction at some level, however small. The endurance of loyalty is another matter, however.

This brings this discussion to a dynamic perspective, which suggests that satisfaction becomes “transformed” into loyalty, after which they share virtually no common characteristics. This is truly an extreme position for it suggests that loyalty can never return to mere satisfaction. Indeed, some have suggested that there is a threshold at which loyalty can “revert” to *dissatisfaction* in the face of repeatedly unsatisfactory purchase episodes. Sometimes referred to as *catastrophe models*, discontinuous jumps are posited within an ordinarily continuous relationship, which is what many assume.

The reason for the ambivalence as to which conception is most accurate is that, even in the perspective taken here, there remain variants of loyalty. In addition to the cognitive-to-action sequence, it is suggested that there are now different degrees of loyalty depending on how many of the synergistic factors presented here are involved. Immersion-based loyalty is supported by the convergence of product, personal, and social forces and the consumer displaying this state has logical, personal, and communal loyalty sustainers. At the same time, competition is easily thwarted by these same forces. Removing any or one of these lowers the consumer's resistance to competitive persuasion. Loyalty supported only by the social environment permits the consumer to look beyond its borders. Loyalty supported only by fortitude is susceptible to "relapse" such as self-doubt, second thoughts, competitive onslaught, and repetitively unpleasant dissatisfactory experiences. Furthermore, as discussed throughout this article, loyalty supported only by product information is subject to competitive counterinformation.

Thus, the dynamic model comes closest to the perspective taken here except that satisfaction does not transform into loyalty as much as it is a seed requiring nurturance. These are the analogies to personal determination and social support. Without these additional factors, satisfaction, much like the seed, stays dormant. The consumer remains satisfied, but does not progress beyond that state. Even a flash of sustenance—like the flash of delight—will not begin the transformation process. Once the seed sprouts, it will grow if the requisites are there. Only the mature version contains the strength of survival despite lapses in its base form, namely, dissatisfaction.

The translation of loyalty to profits. The study of satisfaction as a precursor of loyalty, and exploration of the concept of loyalty itself, brings the discussion to what many considered to be the ultimate goal—profit. Until recently, insufficient data were available to establish the "much talked about" relationship between satisfied and loyal consumers and a firm's profits. While many working in the satisfaction field had assumed that the relationships between satisfaction and

loyalty and between loyalty and profits are inherently intuitive and self-evident, others provide arguments to the contrary.

The reader may remember when stock market valuation models contained only financial and accounting data. They still do. It may seem strange indeed that the customer is not represented beyond mere sales (revenue) in these calculations. True, backward trends are analyzed and forecasts are made based on "hard" data. However, we now have equally hard data on customer satisfaction across industries and countries over time (Johnson *et al.*, 2001). Moreover, it is now recognized that the same customer satisfaction data statistically and significantly add to the explanation of changes (variation) in stock valuations (Morgan and Rego, 2006). Then what of loyalty?

Perhaps the greatest effect of loyalty on profit is the direct influence of a steady stream of future customers. In a manner similar to discounted cash flows, guaranteed future customers allow firms to budget offensive and defensive competitive efforts, to time tactical market moves, and to weather severe attacks by competitors until an appropriate strategy can be mapped. Moreover, since loyal customers, in the pristine case, require little, if any, marketing attention, efforts can be redirected toward product improvement and service enhancement. In the limiting condition, if a firm had an optimal number of perfectly loyal customers who, by definition, could not be swayed away, the firm's marketing costs would be zero. These findings no doubt will be buttressed by new work in the area as these conclusions are explored on a continuing basis.

hedonism: gratification is value

Barry J. Babin and Mitch Griffin

Mill's *Utilitarianism* impresses upon us the fact that gratification is tied to consequences. In other words, one finds value in activities because those activities may bring future contentment. Does anyone really want a root canal? Consumers seek this service because the end result will be greater contentment because of a lack of pain. While this notion is the received view of most consumer behavior – consumers are solving problems through their activities – the fact is that this utilitarian value in no way precludes the more nascent idea that value is also realized from the immediate gratification of these activities in and of themselves (Babin, Darden, and Griffin, 1994). An automobile is purchased because the consumer is able to address the task of transporting oneself, the family, and effects from one place to another. This utilitarian gratification will be realized in the future. However, the actual act of purchasing an automobile can also be directly gratifying. This is particularly true for the car enthusiast, but even a novice will likely feel some excitement taking a new (preferably expensive) car out for a test spin. This immediate happiness produces gratification, which is hedonic value.

The contrast between consumer activities characterized by hedonism, or experiencing things for the value of the experience itself, with activities performed because they are means to future ends, or workings of utilitarian value, provides a great deal of insight into consumers' behavior. For instance, consider the interplay between time and consumption. Although a topic that is not particularly well studied, most marketing management practice addressing time issues is directed toward reducing the time that it takes for a consumer to receive a service or accomplish a task. This is the utilitarian view. Hedonic value, in contrast, releases the consumer from the bounds of time in the sense that hedonism has no time cost. This does not mean that time does not pass, but the time invested now yields value because of the immediate gratification provided, rather than lacking or even diminishing consumer value.

One might ask, which of the two is greater, hedonism or utilitarianism? This is an empirical

question (Babin and Attaway, 2000), but it also is a question that misleads to the extent that it casts these as opposing values. Marketers must provide experiences that provide high value and examples can be found where the provision is accomplished through predominantly utilitarianism (i.e., Wal-Mart) or hedonism (i.e., Disney). But perhaps the best route to truly great marketing is the provision of high utilitarian *and* high hedonic value. Consider how the modern day spa provides services a consumer might have previously received by visiting a hair salon, a nail salon, a massage therapist, a dermatologist, and so forth to receive the same amount of utilitarian value. But, these spas also provide an instantaneously gratifying experience. The consumer can experience hedonism. Fortunately for marketers, this added value is also associated with added payments by the consumer. When the two become inseparable, the experience of the extrinsic value provided by products and services provides intrinsic value in itself, the value experience is maximized.

Eventually, Mill (1861) argues that value is captured in contentment or happiness. Happiness eventually wins out as a greater and more interesting value being ephemeral yet powerful. People will sacrifice current contentment for greater happiness. Interestingly, marketing practice and theory devotes a great deal of attention toward satisfaction and less toward hedonism. Contentment is not nearly as motivating. The state of contentment itself is indicative of homeostasis and thus lacks motive power. However, hedonism leads to attachment and the desire to reexperience the gratification. Thus, perhaps consumer researchers would be well served to consider the relative power of value, particularly hedonic value, over satisfaction.

variety-seeking

Aimee Drolet and Daniel He

Most of the choices consumers face are choices they face regularly and can be viewed fundamentally as being either consistent or inconsistent with their usual habits. On most of these occasions, consumers strive for consistency in their choices. Inconsistency can signal fickleness and fussiness or, even worse, moral and mental weakness. In contrast, consumers who display consistency in their choices are viewed positively, believed to possess personal strength and intellectual competency. Furthermore, consistency makes the task of choosing easier, as it takes less effort to make a choice that has been made before than to reconsider and choose differently. These are some of the benefits of behavioral consistency.

At the same time, the costs of inconsistency appear equally clear. Making the same choice repeatedly means experiencing the same result repeatedly. In one word, consistency is boring. Inconsistency in the form of choosing a variety of options can be stimulating and forestall satiation. It can also be perceived as creative and interesting by others. In short, sometimes inconsistency can be good, and consumers often embrace inconsistency by seeking to vary their behavior. Variety-seeking is a common consumer choice strategy.

The tendency to *variety-seeking*, defined here as switching away from a choice made on a previous occasion, has been found in both interpersonal and intrapersonal consumer choice contexts. In interpersonal contexts, such as a group at a restaurant or bar, consumers will choose an option not chosen by other consumers in the group. They will order a different dish or drink even if their variety-seeking behavior will make them unhappier with their order (Ariely and Levav, 2000). And, in intrapersonal contexts, consumers will switch from choosing more-preferred options to less-preferred options despite lowered satisfaction (Simonson, 1990). Indeed, the tendency among consumers to seek variety in intrapersonal consumer contexts is pervasive enough that it extends beyond the choice of product options to the choice of product choice rules themselves (Drolet, 2002).

Why are consumers so motivated to seek variety in their choice making? Further, what factors moderate the tendency to seek variety? Specifically, what are the situational and person-specific factors that influence the degree to which consumers will endeavor to be consistent versus inconsistent in their choice behavior? This article addresses these questions.

REASONS CONSUMERS SEEK VARIETY

Researchers have offered several reasons why consumers are motivated to seek variety. Consumers seek variety for biological, utilitarian, and psychosocial reasons.

Biological reasons. At the most basic level, the tendency to variety-seek may be “hard-wired.” Animal studies suggest that the desire to vary behavior is innate. Even after there is no new information to acquire through behavioral diversification, animals change their behavior, seemingly just for the fun of it. Likewise, people change their behavior because they can get bored with the repeating same experience over and over.

Smart producers of products respond to consumers’ eventual boredom. For example, classical music, with its frequent repetitions and long movements, can sound tedious even to its own enthusiasts. The composer Joseph Haydn anticipated his own eighteenth century audience’s boredom. He interspersed the gentle, melodic parts of the second movement in his Symphony No. 94 with sudden, thunderous bursts of music. Haydn later nicknamed the symphony the “Surprise Symphony” because the piercing notes he added grab listeners’ attention with something different. They also wake up sleeping listeners.

Stimulation. Whether the products are songs (Ratner, Kahn, and Kahneman, 1999) or snacks (Simonson, 1990), consumers crave something different and choose options that allow them to experience something different. Change is inherently stimulating, and the inherent need for stimulation can be met by changing behavior. By choosing options that have not been chosen before or recently, consumers can increase their level of stimulation. Accordingly, by satisfying their need for

2 variety-seeking

stimulation by variety-seeking in one product category, consumers' tendency to seek variety in another category is less (Menon and Kahn, 1995). Likewise, the need for stimulation can be met by having consumers make choices in complex environments (Menon and Kahn, 2002). In these environments, consumers are less likely to variety-seek.

Satiation. Besides boredom, satiation is another negative psychological consequence of repeated choice. Consumers become satiated with products, and variety-seeking among products is a way to stave off satiation (McAlister and Pessemier, 1982). Consumers also become satiated with product attributes. For example, in an experiment by Mitchell, Kahn, and Knasko (1995), consumers choosing among chocolate candies chose more variety in the presence of a stimuli-congruent scent (chocolate) versus a stimuli-incongruent scent (flowers).

Utilitarian reasons.

Uncertainty reduction. By choosing a mix of products with a mix of features, consumers can meet a mix of needs. Some needs may be known at the time of choice. However, some are not. Variety-seeking is a choice strategy that shields consumers from several sources of uncertainty. The future value of products and product features is one source of uncertainty consumers confront. For example, a consumer might not be able to predict the usefulness of a newly purchased product (e.g., GPS) or the usefulness of one of its features (e.g., voice activation). Another source of uncertainty is future preferences (Simonson, 1990). As consumers, we often do not know what our tastes will be in a year or even tomorrow. So, we cover our bets by choosing variety. We cast a wide net and widen our selection. By doing so, we are better able to cope with this source of uncertainty. Put differently, a strategy of variety-seeking has normative value if one assumes that, due to uncertainty about products and preferences, consumers are testing their utilities for choice options (McAlister and Pessemier, 1982) and choice rules over time (Drolet, 2002).

Simplify choice. Variety-seeking is one way that consumers cope with tough choices. Variety-seeking makes good sense for both

cognitive and emotional reasons. In complex environments, for example, where there are large numbers of product options each described along large numbers of product features, consumers may not have the sufficient cognitive wherewithal to solve choice problems (Mitchell, Kahn, and Knasko, 1995). Variety-seeking is a choice heuristic that frees up cognitive resources. For example, consumers can focus on the relative value of attributes, an easier task than calculating attribute value trade-offs.

Choice problems can be emotionally difficult as well. Choosing one option means forgoing others. Consumers anticipate regret and seek to reduce it. Anticipated regret also drives consumers' unwillingness to make attribute value trade-offs that are emotionally threatening. To consumers, the idea of trading off attributes relevant to their self goals (e.g., personal safety and financial well-being) is an inherently aversive one. For consumers, variety-seeking is one way to avoid having to do so.

Maximize global utility. Variety-seeking makes normative sense if consumers are attempting to maximize global utility as opposed to local utilities (Kahn, Ratner, and Kahneman, 1997). When making a series of choices over time, consumers can choose to maximize the utilities associated with each choice made in the series (i.e., local utilities). Or, consumers can choose to maximize the utility associated with the entire series of choices (i.e., global utility). Maximizing local utilities presupposes that earlier choices have no effect on the satisfaction consumers experience from later choices. This may not always be the case, for example, because of satiation. However, maximizing global utility, that is the utility associated with the entire series of choices, may cause consumers to experience less overall satisfaction (Simonson, 1990).

Maximize retrospective utility. Variety-seeking also makes sense if consumers are attempting to maximize retrospective utility. Ratner, Kahn, and Kahneman (1999) provided evidence that this is sometimes the case. In their research, participants rated their memory for how much they enjoyed sequences of music that were more versus less varied. Participants' retrospective reports of their enjoyment were

higher for the more-varied (vs less-varied) sequence, even though their online reports of their enjoyment were lower for the more-varied (vs less-varied) sequence.

Psychosocial reasons.

Norm conformity. Some variation in choice behavior is viewed more favorably by others compared to no variation in choice behavior. A moderate amount of variation suggests positive values, such as discerning taste, and adaptive personality traits, such as flexibility. In contrast, the complete absence of variation suggests negative values, such as indiscriminant judgment, and maladaptive personality traits such as rigidity. When in the presence of others, consumers who follow a norm of variety-seeking are viewed more positively by others compared to those consumers who do not (Ratner and Kahn, 2002).

Need to appear unique. Another psychosocial reason that consumers seek to vary their choice behavior stems from the desire to be unique. In interpersonal contexts, a consumer will make different choices over others because these choices advance the goal of portraying oneself as unique. The consumer who makes the same choices as others runs the risk of appearing to imitate them. A study by Ariely and Levav (2000) supports this view. In their study, microbrewery patrons were offered the choice of one of the four free beer samples. In a "collective" condition, patrons ordered their samples one by one aloud to the waiter. Thus, each person in the group knew what each of the others ordered. In an "independent" condition, patrons wrote down their choice on individual menus. Thus, other persons in the group did not know what each person had ordered. Consistent with the view that consumers seek variety in order to portray themselves as unique, in both their own eyes and the eyes of others, patrons in the collective condition showed greater variety in their beer choices, suggesting they desired to be unique. They also expressed greater regret when asked if they wished they had made a different choice, suggesting that they had sacrificed their initial choice so as to be unique.

The variety-seeking in this study involved a sequence of individual choices. An implication of its results is that a consumer who is the

first in a group to order can satisfy his or her own particular taste without having to worry about being perceived as unique since no one else in the group has chosen before him or her. Indeed, in follow-up tests, Ariely and Levav (2000) confirmed that consumers in the collective condition who were the first to order were just as satisfied as the consumers in the independent condition. Equal satisfaction implies that these consumers ordered the drink they most preferred and at the same time were able to appear unique. Consumers in the collective condition who were not the first to order may have appeared unique but were less satisfied with their drink order because their choice was contingent on the choices of others.

The desire to appear unique also plays a role in intrapersonal choice contexts. Behavioral change in oneself is associated with perceptions of oneself as unique. People who prize uniqueness separate themselves from others by maintaining a sense of "specialness." People can demonstrate specialness by choosing not to conform to standards of behavior set by others and also to standards of behavior they themselves set. Not conforming to one's own standards reveals a person to be unique as it represents a display of situational abnormality, one aimed at avoiding excessive similarity.

MODERATORS OF VARIETY-SEEKING BEHAVIOR

There are several situational and person-specific factors that moderate the tendency to seek variety and that determine the conditions under which this tendency is more versus less pronounced.

Situational factors.

Mood effects. Past research has shown that positive mood increases variety-seeking. For example, Kahn and Isen (1993) manipulated participants' mood to be positive by giving them a bag of candy. These participants chose more variety compared to participants in a control condition.

There have been multiple explanations offered for the increasing effect of positive mood on the tendency to variety-seek. One explanation is that positive mood is associated with sensation-seeking and novelty-seeking,

4 variety-seeking

and variety-seeking is one way in which people can achieve these ends (Menon and Kahn, 1995). Another explanation is that positive mood increases heuristic processing, and variety-seeking is a choice heuristic that simplifies choice-making (Mitchell, Kahn, and Knasko, 1995). Negative mood is associated with systematic thinking and also monotonous behavior.

Relatedly, heuristic processing is associated with broadened thinking, whereas negative mood is associated with narrowed thinking. Kahn and Isen (1993) suggested that positive mood caused participants in their study to have a more optimistic view of consumption. Besides, positive mood's increasing effect on broadened thinking may lead participants to have a more flexible view as to what products fit in a category, thereby increasing the size of their consideration sets (i.e., the number of product options they would consider choosing).

Presence of others. The presence of a group forces individuals to deal with different goals, goals that can be achieved solely by the individual and goals that are accomplished by both the individual and the group (*see* SOCIAL INFLUENCE). Because these two goals often oppose one another, it may not be possible to meet both if each requires the choice of a different option. For example, when we are at a restaurant with friends, we must choose between these goals: we can either satisfy our own taste by ordering a meal without considering what our friends have ordered or we can portray ourselves as unique by ordering a meal contingent on the orders of others. If uniqueness is the goal, the recommended strategy would be to order an option that our friends do not. If uniqueness is not the goal, the recommended strategy would be to order an option that our friends order.

Ratner and Kahn (2002) demonstrated that the presence of others influences which kind of strategy consumers tend to pursue. Specifically, they found that consumers were more likely to variety-seek when their consumption was public versus private. Their finding implies that variety-seeking is a salient social norm and that compliance with this norm increases social evaluations. When their behavior is being observed,

consumers will choose more variety than they would otherwise. By choosing a variety of products, consumers can appear more interesting, for example, a trait that is socially valued.

Physical confinement. Recent research by Levav and Zhu (forthcoming) found that a physically restrictive space causes consumers to seek more variety. A physically restrictive space arouses feelings of confinement and threatens personal freedom. As a result, consumers develop psychological reactance and try to reclaim their personal freedom by seeking variety. In their view, variety-seeking is a manifestation of the freedom to choose.

In one of their studies, participants were instructed to choose three out of ten candy bars from a bowl placed on top of a table. To get to the bowl, participants had to walk down either a wide aisle or a narrow aisle. They found that participants in the narrow aisle condition chose a greater variety of candy bars compared to participants in the wide aisle condition. In another experiment, participants were confined to either a narrow aisle room or a wide aisle room. They were asked to take a seat at the end of the room. Participants then learned about six charitable organizations – three more well-known and three less well-known – who were seeking donations. Participants were asked about their likelihood of donating to each. Participants in the narrow (vs. wide) aisle room were more likely to donate to the lesser-known charities. Some participants were also given the opportunity to make actual donations to the charities. Among those participants, the actual donation amount was higher in the narrow (vs wide) aisle condition. Levav and Rhu suggest that increased variety-seeking for the less well-known and more unique brands is the result of feelings of confinement and subsequent reactance to these feelings. Consistent with this suggestion, Levav and Rhu found that simply varying perceptions of confinement instead of actual physical confinement induces reactance and increases variety-seeking behavior.

Choice set size. An increase in the number of choice options can not only decrease a consumer's willingness to buy any option but can also lower the satisfaction with choices made from a larger set of choices. When the size of the

choice set increases, it is increasingly difficult for consumers to make a choice among items. One low-effort way for consumers to resolve difficult choice problems is to choose a mix of items. As mentioned, by choosing a mix of items, consumers can raise the odds of choosing a most preferred item and an item that can meet unknown future consumer needs.

Decision timing. The timing of decisions is an important situational determinant of the tendency to variety-seek. Consumers tend to seek more variety when making multiple product purchases simultaneously versus sequentially. An experiment by Simonson (1990) illustrates the effect of decision timing on variety-seeking behavior. Student participants were asked to choose from a set of snacks at the beginning of a class meeting. There were three conditions. In a sequential choice condition, participants made one choice each week for three weeks. In a simultaneous choice for sequential consumption condition, participants made all three choices at one time but received only one item each week. In a third condition, known as the simultaneous choices for immediate consumption condition, participants made three choices simultaneously and received all three snacks at the end of class that same day. Those in the simultaneous choices for sequential consumption condition were significantly more likely to choose a variety of snacks compared to those in the sequential consumption condition. Moreover, participants in the third condition who were given all three snacks the same day were even more likely to choose variety than participants in the other two conditions.

According to Simonson (1990), having to make multiple product purchases simultaneously versus sequentially forces the consumer to confront multiple sources of uncertainty, including the uncertainty due to the inability to predict future preferences accurately since preferences change over time as well as the uncertainty due to the inability to know which among a set of options is the most-preferred. With respect to the latter source of uncertainty, sequential choice making provides the consumer with the opportunity to update their preferences as each choice occasion passes.

Person-specific drivers.

Personality traits. Past research indicates that there are several personality traits associated with the tendency to seek variety versus avoid it. For example, the dispositional drive for stimulation predicts variety-seeking behavior. As mentioned above, a basic human need is the need for stimulation, and this need can be satisfied through varied behavior or the experience of novel stimuli. The extent to which stimulation is needed varies across individuals (*see* OPTIMUM STIMULATION LEVEL). Some people have a higher need for stimulation than others and are more likely to seek out new things. They do so by seeking variety.

Another personality trait that promotes the tendency of consumers to seek variety is the dispositional need for uniqueness. Consumers use rules to solve choice problems. Which rule consumers select from their repertoire of rules depends on various characteristics of choice problems. Past research has demonstrated that the rule consumers select is also independent of choice problem characteristics (Drolet, 2002). In particular, consumers who score high on the need for uniqueness scale tend to vary their selection of choice rules more than consumers who score low on the scale. Consumers who desire to see themselves as different from others can do so by avoiding repeated use of the same choice rule.

People vary in the dispositional tendency to be indecisive and this tendency is associated with increased variety-seeking behavior (Jeong, H.G., and Drolet, A. (2009) The indecisive consumer: delaying decision-making by seeking variety, unpublished research). Highly dispositionally indecisive individuals tend to view the prospect of choice as aversive. Choice-making for them is an experience filled with anxiety, worry, disappointment, and regret. Accordingly, they are reluctant to make choices and avoid doing so. As a result, choice is an activity that often ends in impasse and is deferred until later. In the meantime, the search for new alternatives and new information about alternatives can continue. Variety-seeking appears to be a strategy consumers use to delay a final choice and, as such, is a disproportionately attractive strategy for highly dispositionally indecisive consumers.

Given that chronic indecisiveness is associated with negative emotion, these results

appear at odds with research that has found an increasing effect of positive mood on variety-seeking behavior (e.g., Kahn and Isen, 1993). A study by Jeong, H.G., and Drolet, A. (2009) (The indecisive consumer: delaying decision-making by seeking variety, unpublished research.) reveals that negative mood increases variety-seeking among consumers who are high in dispositional indecisiveness but not among consumers who are low in dispositional indecisiveness. Chronically indecisive consumers report feeling better after choosing a variety of products.

Culture. In individualist cultures such as Western cultures, uniqueness has a positive meaning. In contrast, in collectivist cultures such as East Asian cultures, uniqueness has a negative meaning. Not following group norms of behavior undermines the cohesiveness of a group (see CROSS-CULTURAL PSYCHOLOGY OF CONSUMER BEHAVIOR). When maintaining the strength of a social group is important, and it is especially so for members of collectivist cultures, people must sometimes suppress their personal preferences in the interest of group harmony. In individualist cultures, where personal preferences often take precedence over social preferences, the act of choice is viewed as an act of self-expression. In collectivist cultures, the act of choice is not always associated with the self. These attitudes toward uniqueness and choice have important implications on the extent to which consumers seek variety. The tendency to variety-seek depends on consumers' cultural backgrounds.

Research by Kim and Drolet (2003) shows that consumers from individualist cultures tend to seek more variety compared to consumers from collectivist cultures. Specifically, in one study, US-born participants were more likely than Korean-born participants to vary the choice rules they used. Rule change behavior was not as apparent among Korean-born participants. Kim and Drolet hypothesized that this pattern of results is due to cultural differences in the value of uniqueness and the meaning of choice. In a different study, they used advertisements to prime uniqueness (or not) in both US-born and Korean-born participants. Consistent with their

hypothesis, individuals exposed to advertisements with a uniqueness theme sought to vary their choice rule use more, regardless of cultural background. These findings raise the question of just how "hard-wired" the variety-seeking tendency is given that people's tendency to seek variety depends on cultural assumptions of choice and uniqueness.

Aging. There is some evidence that aging influences the tendency to seek variety depending on decision timing. In the research by Novak and Mather (2007), older adults chose more variety when making choices for immediate consumption than when making choices for future consumption. The amount of variety chosen by young adults did not differ when making choices for immediate versus future consumption.

Novak and Mather (2007) attribute this pattern of findings to older adults' increased emotion regulation abilities. As we age, we tend to focus more on positive information and less on negative information, and this change in focus influences choice. As a result, older adults tend to experience more positive mood. As discussed earlier, positive mood has been linked to increased variety-seeking behavior. If an initial experience is positive, and we would expect it to be more so for older adults who are better at focusing on positive aspects of experiences, an individual should be more willing to try out new things.

One reason older adults experience more positive mood is that they avoid potentially negative experiences. When not making choices in real time and there is no information as to whether the initial experience will be positive or not, older adults choose less variety. Again, there is uncertainty surrounding future preferences and this uncertainty is experienced as a negative one (Simonson, 1990). In the presence of this uncertainty, older adults might be more risk averse, seeking to avoid negative outcomes. They will gravitate toward the familiar. Consequently, they will seek less variety when making choices for future consumption.

CONCLUSION

Variety-seeking is a common consumer choice strategy. This article reviewed several reasons

why consumers view variety-seeking as a useful choice strategy. In addition, this article reviewed several moderators of the tendency to choose a variety of options. Both situational and person-specific factors influence the amount of variety consumers will choose.

In predicting the amount of variety consumers will choose, it is important to consider the interaction among such factors. For example, a person-specific driver like the personality trait need for uniqueness predisposes consumers to seek variety. However, this relationship depends on another person-specific variable, culture, which influences the degree to which a person values uniqueness. In summary, in order to predict the amount of variety consumers will choose, it is important to understand why some consumers are attracted to variety-seeking as a choice strategy whereas others are not. To do so, one must take into account the conditions under which some consumers are more or less likely to variety-seek than others.

family buying

James W. Gentry

Both “family” and “buying” are complex terms. For example, the question of how to define family has gained increasing relevance in postmodernity. “Family” may entail an intact nuclear family, three or four generations under one roof, a gay/lesbian couple, a single parent with children, a step-family, a single person with a network of exceptionally close ties, or even other household types. Most legal definitions are similar in substance to that of the US Census Bureau: “a family is a group of two people or more (one of whom is the householder) related by birth, marriage, or adoptions and residing together.” We prefer the broader definition provided by Galvin, Bylund, and Brommel (2004, p. 6): “networks of people who share their lives over long periods of time bound by ties of marriage, blood, or commitment, legal or otherwise, who consider themselves as family and who share a significant history and anticipated future of functioning in a family relationship.”

“Buying” too has complex meanings, as it involves much more than just the act of purchase. Also embedded in the term are issues of perceived need/desire for the product/service/experience; information search about the stimulus, including where to find it; transportation to the store or event, or the ordering of the item by mail, phone, or Internet; the payment for the item; its use and maintenance after purchase; its disposal (especially intergenerationally, *see* CHILDHOOD SOCIALIZATION AND INTERGENERATIONAL INFLUENCES); and the satisfaction with the memories created.

While Alderson (1957) noted that the family should be the unit of analysis in consumer research, the vast majority of family research in marketing has focused on the individual or, more precisely, on “family” decision making as the linear combination of individual preferences. Much emphasis in consumer family research has been paid to relative influence, in an effort to identify the individual most likely to make the particular decision. Measurement of “relative influence” has usually taken on an either/or perspective, using a competitive framework rather than a cooperative one more

likely in the family context, and precluding investigation into constructs such as “shared influence.” Thus, family consumer research has focused on individual members (Commuri and Gentry, 2000), usually the mother, rather than on interactions within the family. More recent work, however, has relied less on pencil and paper instruments and more on qualitative data that provide deeper insight into processes. An exemplar of such research was Epp (2008), who interviewed the family as a whole, as individual members, in dyads, and in triads in the context of vacation planning.

Family consumer research is an extremely dynamic phenomenon. Family gender norms are changing rapidly owing to societal changes (*see* MARKETING AND FEMINISM) such as the increasing number of households in which the wife makes a higher salary than her husband (over one-third now). Globalization is making the world smaller, and marketers are increasingly dealing with family decision making throughout the world. The most common format in the United States is the nuclear family, whereas family in the developing world is far more extended. At the same time, technology changes are having profound effects on roles within the family; for instance, consider the relative computer knowledge levels, which are generating more influence for teenagers in terms of many search processes. Family buying is a complex topic which will continue to challenge consumer researchers far into the future.

consumer creativity

James Burroughs

Creativity is widely defined as the production of outcomes that are both novel and effective for the given context or issue. Thus, novelty and functionality form the two core dimensions of creativity. The definition of *consumer creativity* follows from the more general definition as a “departure from conventional consumption practice in a novel and functional way” (Burroughs and Mick, 2004, 403). This form of creativity could include the consumer devising a new use for an existing product, altering the form of a product to improve its performance or appearance, or combining two or more products in a unique way.

TWO FORMS OF CREATIVE CONSUMPTION

Instances of individuals exhibiting creativity in consumer behavior are widespread, and generally fall into one of two categories: consumer problem solving and consumer self-expression. In the first instance, the impetus for the creativity is supplied by the environment. Some type of constraint (a lack of time, money, or product availability, being the three most common; Moreau and Dahl, 2005; Bagozzi and Warshaw, 1990) prompts the individual to design his or her own consumption solution. For example, a consumer may lack a necessary ingredient for a recipe and may be forced to improvise, or a consumer who is unable to afford expensive home furnishings may use creativity to take a more affordable product and augment it to look more expensive. Many new product ideas have their origins in consumer creativity (Von Hippel, 1986) (see CONSUMER INNOVATIVENESS), and the potential for tapping consumers as a creative resource (customer cocreation) has attracted considerable attention in recent years.

A second type of consumer creativity is more expressive in nature, such as the alteration of a car or clothing to make a statement about one's individual identity or the culture in which they are a part. Though this creativity is always embedded in a social network, it is not prompted by the environment per se, but rather comes from within the

individual (Holt, 1997; Kates, 2002). Creativity is essential to every person's sense of self-worth, including feelings of autonomy, competence, and relatedness (Deci and Ryan, 2000); in modern society, these needs are increasingly met through consumption behaviors. Because this form of consumer creativity is not evoked to solve an immediate problem, the second dimension is more aesthetic than functional in nature.

There can be considerable overlap between these two forms of consumer creativity and there is no reason that an act of creativity that is highly aesthetic cannot also come in response to a very practical consumption problem. Similarly, mundane problems can be solved in very elegant ways. For this reason, it has been suggested that researchers may want to adopt a three-dimensional view of consumer creativity (i.e., novelty, functionality, and aesthetics), at least in some instances.

ANTECEDENTS OF CREATIVE CONSUMPTION

In addition to trying to understand when and why consumers may engage consumption creatively, research has also tried to understand the factors responsible for producing more creative outcomes. In other words, why are some consumers more creative than others? While a full review of all the contributing factors to creativity is not possible in this article (see Burroughs, Moreau, and Mick, 2008), four are particularly noteworthy: analogical reasoning, intrinsic motivation, domain knowledge, and risk taking.

Generally, creativity is held to flow from a confluence of interacting factors rather than any single factor. However, one factor has captured more interest and intrigue from researchers than perhaps any other, and this is analogical reasoning. Almost by definition, creativity involves taking an idea from a disparate domain and recognizing its relevance to a completely different situation. Individuals who are able to think analogically or metaphorically (as opposed to literally), consistently come up with more creative responses to consumption issues (Burroughs and Mick, 2004; Dahl and Moreau, 2002). That said, we still have very limited understanding of this fascinating cognitive process and its role in creativity.

Two less-explored but important areas of consumer creativity are domain knowledge and risk taking. The role of domain knowledge for creativity is controversial. Some advocate that a knowledge foundation is necessary for new insights to occur (Weisberg, 1999) (*see KNOWLEDGE ACCESSIBILITY*). However, others have found that too much knowledge leads to rigid thinking and is therefore detrimental to creativity. This has resulted in the inverted-U hypothesis, that creativity in an area is optimized by substantial but not overwhelming knowledge. Finally, creativity is an emergent and uncertain enterprise; thus individuals who are creative exhibit a high tolerance for ambiguity, as well as a proclivity for novelty seeking and risk taking (Sternberg and Lubart, 1996).

Another important factor is intrinsic motivation. Intrinsic motivation is sustained and intense interest in a consumption activity out of curiosity or enjoyment. Because people often engage in acts of consumption because they enjoy them (for example, a hobby), and because thinking creatively is mentally taxing, intrinsic interest is essential to the sustained effort needed to bring a potentially creative idea to fruition (Amabile, 1996).

PROCESS FACTORS IN CREATIVE CONSUMPTION

Finally, a nascent area of research is trying to understand the creative process, or how creative outcomes come about. Largely based on the cognitive tradition, creativity is widely believed to have four stages: exploration, fixation, incubation, and insight (Ward, Smith, and Finke, 1999). Exploration is a preparatory stage during which many combinations of ideas and possibilities are explored (mentally and sometimes physically). Fixation is when a consumer becomes entrenched in thinking about a consumption problem or issue in one way, which often leads to mental blocks and frustration. The consumer eventually becomes fatigued and desists, at which point the process enters the incubation period. Though the consumer is no longer actively thinking about the problem, the brain continues to unconsciously contemplate it. However, the linkages that were so tightly held are now relaxed allowing new and

more distal mental linkages to form. The result can be an abrupt and wholly unanticipated new approach or solution, known as the *moment of insight* (Burroughs, Moreau, and Mick, 2008). As with many other areas of creative cognition, how the brain is able to accomplish this remarkable feat is still largely a mystery.

In sum, creativity is a useful, multifaceted, and underdeveloped issue in consumer behavior. There are many opportunities for research on this topic.

how consumers respond to price information

Kent B. Monroe

PROCESSING OF PRICES AS NUMERICAL INFORMATION

We use numbers virtually every day in our lives, for example, as a form of identification of ourselves, to make telephone calls, or to pay a bill. However, the apparent ease with which we use numbers hides the fact that very complex cognitive processes are required to recognize numerical stimuli, or to make numerical comparisons or calculations. In this section, we review research results that help us understand the complexity of processing price information.

Complexity of numerical cognition processes.

Number processing involves the ability to mentally manipulate sequences of words or symbols according to fixed rules. This process is of interest when a consumer is calculating or estimating the numerical difference between two prices, or adding the surcharge of shipping and handling to determine the total cost of the purchase. To compare prices, or judge the differences in prices requires that we access and manipulate a mental model of quantities similar to a mental number line. Approximation is the process by which Arabic or verbal numerals are first converted into an internal magnitude representation in our minds. This encoding is automatic, fast, and independent of which number is encoded.

When numbers are used to denote amounts, such as prices, the magnitude of the number becomes meaningful. When a price is encoded as a magnitude, either the exact value or an approximation of the exact value of the price is encoded and represented in memory. Given this encoding, we are interested in learning how people process price information when making price comparisons, when discriminating between two prices, whether the oddness of a price influences processing, and how a series of numbers that comprise a price may be remembered.

Comparing and discriminating numbers. The *distance effect* indicates that it takes longer to decide that 8 is larger than 6 than to decide that

8 is larger than 2. Moreover, the *magnitude effect* indicates that, for equal numerical distance, it is easier to discriminate small numbers (e.g., 1 vs 2) than larger numbers (e.g., 8 vs 9). The digit 5 has a special status in our numbering system. The digits 2, 3, and 4 are initially encoded as small, while the digits 6, 7, and 8 are encoded as large. That is, the mental representation of numbers below 10 is divided into numbers above and below 5. Thus, in a price comparison, task people first automatically encode the two prices independently and then classify the prices as “small” or “large” (Monroe and Lee, 1999).

When judging which number in a pair is *larger*, people find the task easier when both numbers are large than when both are small. The opposite is true when people have to decide which item is smaller. It has been shown that when people are trying to determine which of the two numerals is larger, it is an easier task if the larger of the compared numerals is displayed in larger font size. Similar results occur when people are trying to determine the smaller of compared numerals and the smaller numeral is displayed in smaller font size (Coulter and Coulter, 2005).

As suggested above, some processing of price information may be more automatic than others. Also, price comparisons in the lower price range (i.e., smaller numbers involving fewer digits), which are more typical for most supermarket purchases, may be more likely to be processed automatically. Moreover, identifying whether a specific price is higher than another price will be processed faster when that price is indeed higher than the comparison or reference price.

The left digit and price endings effects. Research has demonstrated that under a variety of different tasks and judgments, even digits are processed faster and/or more accurately than odd digits. Possible reasons for this odd price effect on consumer behavior can be divided into effects of *price perception* (how people encode price information into their minds) and effects of *price cognition* (how people process and interpret the price information).

Consumers have a tendency to underestimate 99¢-ending prices. Given that consumers seem to have more difficulty recalling odd-ending prices than round prices (e.g., \$300) could

2 how consumers respond to price information

imply that odd-ending prices are not encoded completely or that \$300.00 is easier to encode as a magnitude than \$299.99. One reason is prices ending in 99¢ are more difficult to process and as a result people may encode an approximation of the price rather than the precise price. Also, people tend to misperceive the difference between two prices when the left-most digits differ, odd price endings are used, and computations are necessary to determine the magnitude of difference (Manning and Sprott, 2009; Thomas and Morwitz, 2009). Knowing that perceived price has *meaning* that differs from its objective meaning in terms of perceived monetary sacrifice suggests that using inappropriate price endings could have unwanted implications for sellers.

Thus far, we have considered only a single price for a product or service, what are called *unidimensional prices*. However, offers often are provided with multiple price attributes. For example, an automobile may be advertised with a price for the vehicle, along with a combination of monthly payments, amount of down payment, and effective interest rate. Catalog and Internet offers typically quote selling prices and shipping and handling charges. When there are multidimensional prices, additional computations are required to evaluate the offer, some of which can be difficult. Also, some retail price promotions provide multiple discounts, for example, 40% off all merchandise with an extra 15% off if purchased at a certain time. When odd price endings are used, or when an item has a complicated price, for example, \$23 977, these types of offers affect consumers' abilities to evaluate prices and to know exactly what they are paying for the item. The computational difficulty associated with multidimensional pricing is influenced by the price ending used, the perceived numerical distance between comparative prices, as well as the calculations necessary to determine the price to be paid.

Remembering prices. Previous research has attempted to determine the extent that consumers do remember prices they have paid assuming that consumers are *consciously* involved in their purchasing behaviors and that product evaluations and choice decisions are a function of what information is accessible in memory. What is accessible in memory often is measured by

what consumers *can consciously remember*. The notion is that consumers frequently make judgments that a particular item is "too expensive" or "a real bargain" based on some prices that they recall from past shopping experiences, and these recalled prices form a basis on which the consumers' reference price is formed.

However, research measuring consumers' ability to remember prices of recently purchased items report that a relatively low proportion of consumers can accurately recall prices of recently purchased products (Monroe and Lee, 1999). Such research evidence could lead to the conclusion that consumers do not consciously attend to price information when either considering or actually making purchase decisions. Nevertheless, a shopper who does not recall the price of, say, the box of snack bars she just put into her cart may tell the interviewer that it is expensive. Thus, consumers may encode price information into memory in different representational forms.

Consumers may process and retrieve price information either consciously or nonconsciously. When price information is processed consciously, consumers pay attention to the price, make judgments regarding the value of the product using information that is either present in the external environment or retrieved from memory, and finally make a purchase decision. When consumers consciously process the actual price information, a magnitude representation of the price and their evaluative judgment may be transferred from working memory into long-term memory (Vanhuele, Laurent, and Dreze, 2006).

Alternatively, it is possible that only their comparative or evaluative judgments, and not the actual price information, are transferred into long-term memory. In this case, the consumers would not be able to recall the actual price when asked to do so at a later point in time. This scenario is consistent with the idea that an evaluation of a product may be more easily remembered than the price when the evaluation is formed at the time of exposure (Adaval and Monroe, 2002). When price information is processed nonconsciously, the consumer does not pay particular attention to the prices. Nonetheless, a judgment regarding the value of the product and a purchase decision may have been made. When

nonconscious processing of price information occurs, the consumer may not be able to recall the price of the product at a later time, but she may still be able to indicate that the product is “too expensive,” “a bargain,” or “reasonably priced,” indicating that the price information has been processed and evaluated. Thus, consumers’ price comparisons and evaluations are affected by price information to which they have been previously exposed, even though they may not consciously remember the actual prices relevant to their judgments.

REFERENCE PRICES

Price judgments are comparative in nature. That is, for consumers to determine that a price is acceptable, too high, or low, that price must be compared to another price, whether that other price is in memory or available nearby. The other price serves as a comparison standard or reference price. Researchers have proposed and provided evidence for the existence of reference prices (Mazumdar, Raj, and Singh, 2005). These propositions have been based on adaptation-level theory and assimilation-contrast theory (social judgment theory).

Adaptation-level theory. Adaptation-level theory assumes that stimuli are judged with respect to internal norms (*adaptation levels*) representing the combined effects of present and past experiences. For any consumer, the adaptation-level price for a specific product category is a function of the frequency distribution of prices for that category, the relative magnitude of the prices, the range of prices, and the dispersion of prices from the average price. It is influenced by past experience and by the sequence that the consumer observes the prices for the category. The concept of adaptation level or reference price supports the important point that *consumers judge or evaluate prices comparatively*; that is, the acceptability of a price is judged by comparison to another price.

When considering how consumers perceive prices, it has to be borne in mind that perception is relative. In other words, a specific price is compared to another price, or a reference price. When sellers advertise both the offered price and a (higher) comparative regular price, they

are suggesting a reference price for consumers’ comparisons. To convince consumers to use the higher price as a reference price, sellers may include such words as “formerly,” “regularly,” and “usually,” to describe the higher price. The judgment of acceptability depends not only on consumers’ price expectations but also on information provided in promotions or advertisements.

Assimilation-contrast theory. Similarly, the basic tenet of assimilation-contrast theory is that new stimuli encountered by an individual are compared against a background of experience with the stimuli category. This experience forms an individual’s reference scale that serves as a basis for the individual to compare and evaluate other stimuli *perceived as related to* the reference stimuli.

If a new price is encountered for evaluation, it may also serve as an anchor in that it may result in a changing of the reference scale. Both adaptation-level theory and assimilation-contrast theory suggest that the reference price range should move in the direction of this new price. If the new price is relatively high, the reference price range moves toward the new price and the previously lower prices become further away from the reference price scale. If judgments of these previously perceived low prices in the category do not change when the new price is encountered, an *assimilation effect* is said to occur. The assimilation effect occurs because the new price is perceived as similar to the reference prices. However, if the new price moves the reference price range sufficiently higher, the original low prices will be perceived as lower than previously, and a *contrast effect* is said to occur.

The prevailing range of prices for a product category affects the consumer’s reference price for that category. Since the width of the price range is affected by the lowest and highest price (end prices) in the range, these two end prices also affect price judgments. Thus, there are three different price cues affecting price judgments: the reference price, the lowest price, and the highest price in the range of prices available for judgment. Prices used by consumers to judge other prices (reference price, end prices) are called *anchoring stimuli*. By *price judgment* we

4 how consumers respond to price information

mean a consumer's assessment of whether a price is too low, just right (acceptable), or too high.

In summary, a reference price is any price in relation to which other prices are perceived. These two theories clearly suggest that a reference "price" is actually an internally held judgment scale concerning prices for a product-price category.

PRICE THRESHOLDS

Absolute price thresholds. An important concept introduced in our discussion of reference price was the *acceptable price range*. This concept implies that a consumer has a lower price threshold and that there are prices greater than \$0, which are unacceptable because they are considered to be too low, perhaps because consumers are suspicious of the product's quality. Also, it is recognized that at specific points in time there is a maximum price that consumers are willing to pay for a product or service (upper price threshold). The important point is that there is not just one acceptable price for a product or service; instead, there is some range of acceptable prices.

Variations in the level and width of consumers' acceptable price ranges are influenced by a number of factors. For a specific product category, the upper acceptable price threshold is lower if consumers perceive that there are similar alternative offerings available. However, if customer satisfaction increases or consumers become more loyal, then the upper threshold tends to be higher. Conversely, if customer satisfaction declines leading to lower consumer loyalty, consumers' upper price threshold would become lower. If consumers are not knowledgeable about prices for a product category, their acceptable price ranges tend to be relatively narrow and their lower and upper acceptable price limits tend to be lower than more knowledgeable consumers. Consumers who infer quality on the basis of price tend to have higher acceptable price levels, higher upper acceptable price limits, and wider acceptable price ranges. Finally, consumers who are consciously concerned about prices tend to have lower acceptable price levels, lower upper acceptable price limits, and narrower acceptable price ranges (Monroe, 2003).

Differential price thresholds. Usually a consumer has alternative choices available for a purchase and selects from among these choices. The prices of these alternative choices may provide cues that facilitate the decision process. However, even if the numerical prices are different, it cannot be assumed that the prices are *perceived* to be different. Hence, the problem becomes one of determining the effect of *perceived price differences* on consumer choice.

The perception of a price change or difference depends on the magnitude of the change or difference. Also, people are more sensitive to perceived price increases than to decreases. The immediate implication is that consumers will be more sensitive to price changes for some products, that is, have lower differential price thresholds. But, for other products, a similar price change may not be perceived. The differential price issue is how the price of one product is perceived to differ from the price of another offering that consumers believe is an alternative choice to consider. These alternative products could be sold by different sellers competitively or they could be alternative models of the product sold by a single seller.

PRICE AND CONSUMERS' PERCEPTIONS OF VALUE

Behavioral research has provided explanations of how people form value judgments and make decisions when they do not have perfect information about alternatives. These findings further our understanding of why consumers may be more sensitive to price increases than to price decreases, and how they respond to comparative price advertisements (e.g., regular price \$65, sale price \$49), coupons, rebates, and other price promotions.

In this section, we return to the idea that people seldom are good information processors and that they often take shortcuts (decision heuristics). These shortcuts may lead to errors in judgment and choice, but they may also facilitate the choice process. Several of these decision heuristics can help us understand how price influences perceptions of value and eventual product choice. First, the *context* of the purchase decision, including the way the offer is presented, *frames* the consumer's evaluation and

choice. For example, the way a sale is advertised will influence consumers' judgments about the value of the offer. The context of the place of purchase affects a consumer's internal reference price or expectations about prices in that place.

Another important point is the *anchoring* effect mentioned earlier. As we observed earlier, the order of price presentation anchors consumers' judgments as do the low or high prices in a product line. Also, people tend to adapt to prices that are presented as the original prices. For example, antique dealers often overprice their items, anticipating that consumers will want to negotiate over the price. The initial high price serves as an anchor, and generally the negotiated price is higher than it would have been without this initial high anchor price. Prices that are irrelevant to the considered purchase can anchor judgments about what is acceptable to pay for an item (Nunes and Boatwright, 2004).

Perceived value represents a trade-off between consumers' perceptions of quality and sacrifice. The degree that consumers believe there is a price-quality relationship influences their value perceptions and willingness to buy. When comparing prices, consumers' judgments are influenced by the relative or perceived differences between the actual or offer price and the reference price. Using these points about price perception, we now show how perceived price influences consumers' judgments of value.

The price-perceived quality relationship. Consumers do not use price solely as a measure of cost (sacrifice). They also use price as an indicator of product quality (Rao and Monroe, 1989). Consumers are assumed to assess product or service quality by the use of cues. Products, services, or stores can be conceptualized as consisting of an array of cues that may serve as indicators of quality. Consumers may use these cues if the cues help them predict the quality of the product or service and when they have confidence that they can use and judge the cues accurately. *Extrinsic cues* are product-related attributes—price, brand name, packaging, but they are not part of the product. *Intrinsic cues* are also product-related attributes, but they cannot be changed without altering the physical properties of the product. Consumers rely on extrinsic cues and intrinsic cues when evaluating quality.

When consumers become familiar with a product they are more likely to use intrinsic cues rather than price or other external cues as indicators of product quality. However, highly familiar consumers (experts) use either price or intrinsic cues as indicators of quality, depending on whether their knowledge includes information about the reliability of price as a quality indicator. That is, if consumers know that there is a positive price-quality relationship in the market, they will probably use price as a quality indicator. It has been argued further that if consumers know that there is a weak price-quality relationship in the product market, they will be more likely to use intrinsic product cues to assess product quality. Thus, the strength of the use of price or other external cues, such as brand or store name, as indicators of product quality, depends on the relative perceived differences between different cues and the degree that consumers know about the product and actual price-quality relationships.

The price-perceived monetary sacrifice relationship. A consumer's perceptions of the sacrifice, "give up," or loss incurred by paying the monetary price for a product may vary according to a variety of situations and conditions. For example, does a consumer perceive paying \$90 for a dental cleaning to be an equivalent sacrifice as paying \$90 for a ticket to a concert or sporting event? Indeed consumers may perceive equivalent monetary prices as representing very different sacrifices.

For some products or services, consumers would prefer not to make the expenditure. Thus the perceived sacrifice of paying a specific price for some products is psychologically more "painful" than others, even though the monetary outlay may be equivalent. Thus, the more the consumers are reluctant or hesitant to spend money on certain products, the more likely are they to search for bargains or lower prices, and they will be more sensitive to price changes and to price differentials between alternative choices.

If consumers believe that sellers have increased prices to take advantage of an increase in demand, or a scarcity of supply, without a corresponding increase in costs, then such price increases would be perceived to be unfair (Bolton, Warlop, and Alba, 2003; Xia, Monroe,

6 how consumers respond to price information

and Cox, 2004). In situations where one category of consumers receive the benefit of a lower price for an equivalent product or service but another category of consumers do not, the price-disadvantaged consumers may perceive that the price they pay is unfair (Haws and Bearden, 2006). Such situations typically occur when sellers provide discounts for consumers with certain characteristics, for example, age or preference status. Further, if there is no perceived discrepancy between the effort that these favored consumers make to qualify for the lower price relative to the disadvantaged consumers, then they will be receiving the same benefits as the disadvantaged consumers but incurring a smaller monetary sacrifice. Similarly, if consumers perceive that the prices they pay are higher than their comparable reference group, then such prices are likely to be perceived to be unfair.

Thus, a price judged as unfair can lead to lower perceptions of value and a reduction in willingness to pay; that is, a perceived disadvantaged price inequity, or a loss, increases consumers' perceptions of sacrifice, thereby decreasing their perceptions of value and willingness to buy.

INTEGRATING PRICE, QUALITY, AND SACRIFICE INFORMATION

When consumers use price as an indicator of cost or sacrifice, increasing price has the effect of reducing perceived value for the product or service. On the other hand, if consumers use price as an indicator of quality or benefits, increasing price has the effect of increasing perceived value. We know that consumers generally are not able to assess perfectly product or service quality (the ability of the product to provide satisfaction). We also know that perceptions of monetary sacrifice for the same specific price may vary according to whether the price is perceived to be fair, the context in which the price is presented, the consumers' acceptable price range, and the extent that consumers are concerned about price. We also understand that perceived value represents a mental trade-off between consumers' perceptions of quality and sacrifice and is positive when perceptions of quality are greater than their perceptions of sacrifice.

A very important issue is how consumers are able to integrate these different bits of information to determine their overall perceptions of value. In other words, information about the product or service attributes and benefits represents positive information (i.e., what the consumer gains from acquiring the product or service). Considering price as an indicator of cost represents negative information (i.e., what the consumer gives up when acquiring the product or service). Attempting to integrate positive and negative information simultaneously to determine an overall value judgment is a difficult mental task.

Although we have not been able to clarify the exact nature of this trade-off between perceived quality and sacrifice, there are some important implications given what we do know. The weight consumers attach to quality and sacrifice depends on the relative magnitude of the product's price. Generally, both quality and sacrifice are perceived to be low when price is perceived to be relatively low, and to be high when price is perceived to be relatively high. However, when evaluating a low-priced product, consumers appear to weigh quality more heavily than sacrifice, thus judging the product as low in value. Yet, when judging a high-priced product, consumers tend to weigh sacrifice more heavily than quality, again judging the product as low in value. These generalizations assume that consumers have sufficient motivation and cognitive resources to process the price and other attribute information to determine product value (Suri and Monroe, 2003). However, these assumptions about motivation and available cognitive resources are not always correct.

DECOMPOSING PERCEIVED PRODUCT VALUE

The overall perceived value of a product being evaluated is its (i) *acquisition value* (the expected benefit to be gained from acquiring the product less the net displeasure of paying for it) and (ii) *transaction value* (the perceived merits or fairness of the offer or deal) (Grewal, Monroe, and Krishnan, 1998).

Acquisition value. Consumers' perceptions of acquisition value represent a cognitive trade-off between the benefits they perceive in the product

and the sacrifice they perceive to be required to acquire the product or service by paying the monetary price of the product. In part, the perceived benefits of a product are related to the consumers' judgments about the product's quality. Lacking perfect information about the inherent quality of the product, many consumers tend to believe that there is a positive relationship between a product's price and its quality ("You get what you pay for"). Thus, other things remaining the same, a higher priced product would be perceived to provide more benefits because of its higher perceived quality. However, at the same time, a higher price increases consumers' perceptions of their sacrifice. Thus, within some range of prices, the perceived benefits in the product will be larger than the perceived sacrifice, and consumers will perceive that there is positive acquisition value in the product. Generally, the greater the perceived acquisition value, the greater is the likelihood that consumers would be willing to purchase the product. However, besides evaluating the product's value, consumers also evaluate the offer itself.

Transaction value. *Transaction value* is defined as the consumers' perceived merits of the offer or deal. Of concern here is how consumers evaluate a purchase situation in which the consumer gains a product but gives up the money paid for the product. Consumers first *judge* the value of the offer and then *decide* whether to make a purchase. To explain the role of price in this process, three price concepts are used. The *perceived benefit* of the product is equivalent to the utility inherent in the *maximum acceptable price* the consumer would be willing to pay. The *acquisition value* of the product is the perceived benefits of the product at this maximum price compared to the actual selling price, that is, $p_{\max} - p_{\text{actual}}$. The *transaction value*, or the perceived merit of paying the actual price, is determined by comparing the consumer's reference price to the actual price, that is, $p_{\text{ref}} - p_{\text{actual}}$. Transaction value is positive if the actual price is less than the consumer's reference price, zero if they are equal, and negative otherwise.

Researchers have discovered that when transaction value is present it enhances acquisition value, but does not directly influence consumer

behavior (Grewal, Monroe, and Krishnan, 1998). Thus, acquisition value is determined by the consumers' perceptions of quality or benefits to be received plus perceived transaction value, which represents the comparison of the selling price to the consumers' reference price. One important implication of the finding that perceived transaction value enhances consumers' perceived acquisition value is consumers need to feel confident that they either can determine quality prior to purchase, or they can infer quality because the various signals of quality used by the sellers are appropriate indicators of quality.

SUMMARY

Throughout this article, we have developed a behavioral explanation of how consumers perceive price and how these perceptions influence their perceptions of value. Adaptation-level theory indicates not only that there is a reference price but also that it changes. Reference price is affected by contextual effects such as frequency of previous price changes, consumers' expectations about future prices, the order that price information is presented to consumers, the advertisement of prices, and the intensity of price promotion.

Assimilation-contrast theory indicates that there is a range of acceptable prices. This theory also suggests that the acceptable price range may be affected by the amount of price variation for a product category as perceived by consumers. Another implication derived from assimilation-contrast theory is that there is likely to be a range of prices around the reference price within which little change in demand is likely in response to a price change, that is, the price resulting from the price change may not be perceived as very different.

Finally, the psychological argument recognizes that people respond differently to perceived gains and perceived losses and suggests that consumers are more sensitive to price increases (perceived loss) than to price decreases (perceived gain). However, once the price difference (i.e., $p_{\text{ref}} - p$) is perceived to be important by the consumer, there is likely to be a more noticeable change in demand. These price differences can occur because of either a price

8 how consumers respond to price information

increase or decrease, or because of comparative price advertising in which the seller provides an external reference price for comparison.

consumer behavior analysis

Gordon R. Foxall

INTRODUCTION

Although the main theoretical perspective of consumer research has been cognitive, behaviorism receives intermittent mention as a possible contributor, though its potential for understanding consumer choice remains underdeveloped. Some consumer theories incorporate it to deal with routine aspects of consumer behavior, while other treatments approach it as a source of marketer, especially retailer, tactics. The possibility that behaviorism provides insights into the explanation of consumer choice has been neglected. *Consumer behavior analysis* attempts to redress the balance by exploring the nature of behaviorist explanation and its capacity to enlighten consumer research.

Especially in terms of the theoretical and empirical advances made by behavior analysts in the field of verbal behavior and behavioral economics during the last two decades, behaviorism promises to extend the investigation and explanation of consumer behavior beyond the limits of a purely cognitive approach. Behavioral economics, in particular, combines the rigor of operant theory with the methods of experimental economics with the aim of understanding aspects of consumer choice that cognitive consumer psychology has often neglected, such as gambling, addiction, and health-related behaviors as well as more routine features of consumer behavior such as product and brand choice. Consumer behavior analysis adds to this the contextual framework of consumer decision making in marketing-oriented economics, adding further to the interdisciplinary base of the psychological investigation of economic behavior.

THE BEHAVIORAL PERSPECTIVE MODEL

The original aim of the research program was to ascertain whether a model of consumer choice based on a radical behaviorist framework was feasible, and, if so, what the epistemological nature of such a route to explanation would be (Foxall, 2004a). So the aim has never been

to change the paradigm in consumer research in favor of behaviorism, but to test a radical behaviorist depiction of consumer choice to its limit, adding in other approaches to explanation only as and when they became essential. The earliest stages involved critiques of the central explanatory devices assumed in consumer research at the time, notably the ideas that attitudes and intentions inevitably precede, prefigure, and determine consumer behavior, or that novel behavior on the part of consumers was explicable in terms of underlying traits of “innovativeness.” The development of the sought-after model of consumer behavior based on radical behaviorism resulted in the behavioral perspective model (BPM), which is an elaboration of the “three-term contingency,” the basic explanatory device of operant psychology in which a discriminative stimulus (S^D) marks the occasion on which a particular response (R) is likely to be rewarded or reinforced (S^R), that is, to increase in frequency, or punished (S^P), that is, to decrease. The three-term contingency is usually depicted as

$$S^D : R \longrightarrow S^{R/P}$$

where $:$ indicates that the probability of an operant response is increased in the presence of the S^D , while by definition that response leads to consequences that are reinforcing and/or punishing. The model adapts these key elements to suit the interpretation and prediction of human economic behavior in affluent societies. The BPM is shown in Figure 1.

Consumer choice is the outcome of the consumer’s learning history meeting the current consumer behavior setting, the point at which the experience of consumption meets a new opportunity to consume. This intersection is the *consumer situation*, the immediate determinant of approach/avoidance responses involved in purchase and consumption. The *consumer behavior setting* comprises the stimulus antecedents of that behavior, some of which would have been present on earlier consumption occasions. Given the individual’s learning history, that is, past choices and the reinforcing/punishing consequences they have had, these initially neutral stimuli are transformed into the discriminative stimuli

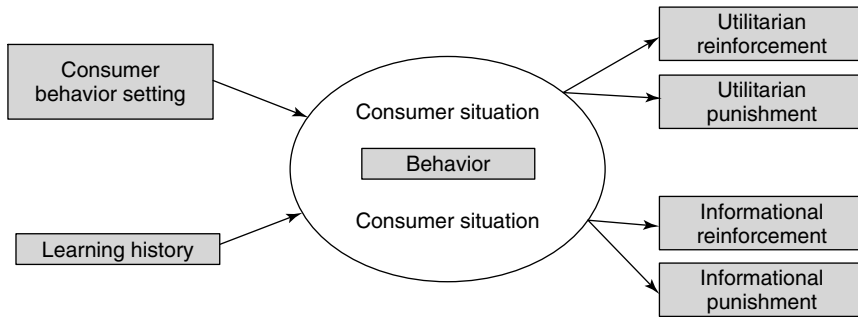

Figure 1 Summative behavioral perspective model.

that set the occasion for current choice; in particular, the individual's consumption history invests them with meaning, in the sense of a capacity to generate specific kinds of approach and/or avoidance behaviors, which produce consequences that regulate the rate of recurrence of the behaviors that produced them. The consumer situation consists also of motivating operations (MOs) such as rules that invest the consequences inherent in the discriminative stimuli with additional motivating or inhibitory power by making the consequences of radical behaviorism appear more or less reinforcing, more or less punishing.

The consumer behavior setting. Like the three-term contingency, the BPM specifies behaviorally antecedent stimulus conditions (the behavior setting) but combines the concepts of discriminative stimuli and motivating operations by means of the construct of behavior-setting *scope*, the extent to which these setting elements encourage or inhibit the behavior predicted to occur in such settings. Settings of purchase and consumption are all *relatively* open, but differ from one another along a restricted continuum of closed-open consumer behavior settings. Waiting in line at the bank to pay in a check occurs in a relatively closed consumer behavior setting: there is probably no alternative to being there and waiting until a teller becomes available, standing in an orderly fashion is encouraged both by the physical style of the building and by the social arrangements, deviation from the established behavior program of the setting is likely to be punished by stares or glares. An open consumer behavior setting encourages a

wider range of alternative behaviors. In a bar, for instance, all types of beverages and snacks may be available, there may be TV to watch, talking loudly may not be discouraged, and even singing and dancing may be possible. The customer is free to leave at any time, even if only to go to another bar in the vicinity – at least far freer than he or she would be to leave the bank and find another at which to present the check.

Patterns of reinforcement. The consequences of economic behavior fall into three types: utilitarian reinforcement, which consists in the functional outcomes of behavior, informational reinforcement, which stems from the symbolic outcomes, principally performance feedback, aversive/punishing consequences, and the costs of purchase and consumption. Such aversive outcomes can themselves be subdivided into those that are utilitarian in nature and those that are symbolic. Utilitarian reinforcement consists in the direct usable, economic, and technical benefits of owning and consuming a product or service, while informational reinforcement inheres in benefits of ownership and consumption, which are usually social in nature and consist in the prestige or status as well as the self-esteem generated by ownership and consumption. The driver of the cheapest car available is principally concerned with the utilitarian benefits that all cars provide: most obviously, door-to-door transportation. Informational reinforcement, on the other hand, is more likely to involve a lifestyle statement by which the consumer seeks to convey his or her social status or to bolster esteem and/or reported feelings of self-esteem. The driver of a Porsche

not only clearly gets from A to B in it but also receives social esteem and status from others as well as personally conferred self-esteem. These constitute symbolic rewards of consumption. Most products have an element of both the instrumental and the symbolic. A mobile phone not only provides communications services when and where the consumer wants them; because it has interchangeable colored cases, it may also signal to that consumer's social group that he or she is "cool" (or, a year later, "not so cool").

Patterns of reinforcement, based on combining high and low levels of utilitarian reinforcement and high and low levels of informational reinforcement, suggest four operant classes of consumer behavior (Figure 2). The four broad classes of consumer behavior can be inferred as follows. (i) *Accomplishment* is consumer behavior reflecting social and economic achievement: acquisition and conspicuous consumption of status goods, displaying products and services that signal personal attainment. (ii) *Hedonism* includes such activities as the consumption of popular entertainment. (iii) *Accumulation* includes the consumer behaviors involved in certain kinds of saving, collecting, and installment buying. (iv) *Maintenance* consists of activities necessary for the consumer's physical survival and welfare (e.g., food) and the fulfillment of the minimal obligations entailed in membership of a social system (e.g., paying taxes). Both types of reinforcers figure to differing extents in each of the four classes. Adding in the scope of the current behavior setting leads to the eightfold way depicted in Figure 3, which shows the variety of contingency categories that exclusively constitute a functional analysis of consumer behavior. We take a closer look at the four broad operant classes of

consumer behavior with the added complexity of consumer behavior–setting scope added in.

Accomplishment. In an open setting, this consists, in general, in the *purchase and consumption of status goods*: luxuries and radical innovations such as exotic vacations and iPhones. The items in question are possessed and used for the pleasure or ease of living they confer, the well-being they make possible for the individual; they thereby provide extensive hedonic rewards. As status symbols, their conspicuous consumption strengthens the behavior in question. They attest directly, and often publicly and unambiguously, to the consumer's attainments, especially economic. Goods in this category are usually highly differentiated – by novel function in the case of innovations, by branding in the case of luxuries. In a closed setting, accomplishment can be generally described as *fulfillment*, personal attainments gained through leisure, often with a strong element of recreation or excitement as well as achievement. It might, for instance, include both the completion of a personal development seminar and gambling in a casino, both of which are maintained by high levels of utilitarian and informational consequence in fairly closed settings.

Hedonism. In an open setting, this consists of *popular entertainment*: viewing TV game shows, which provide near-constant utilitarian reward, or reading mass fiction, which contains a sensation on almost every page. iPods and, in their day, DVDs have made such reinforcement more immediate to the point of ubiquity. Mass culture presents frequent and predictable, relatively strong and continuous hedonic rewards, which are not contingent on long periods of concentrated effort. The arrangement of reinforcers is such that viewing,

| | High utilitarian reinforcement | Low utilitarian reinforcement |
|----------------------------------|--------------------------------|-------------------------------|
| High informational reinforcement | Accomplishment | Accumulation |
| Low informational reinforcement | Hedonism | Maintenance |

Figure 2 Operant classes of consumer behavior defined by pattern of reinforcement.

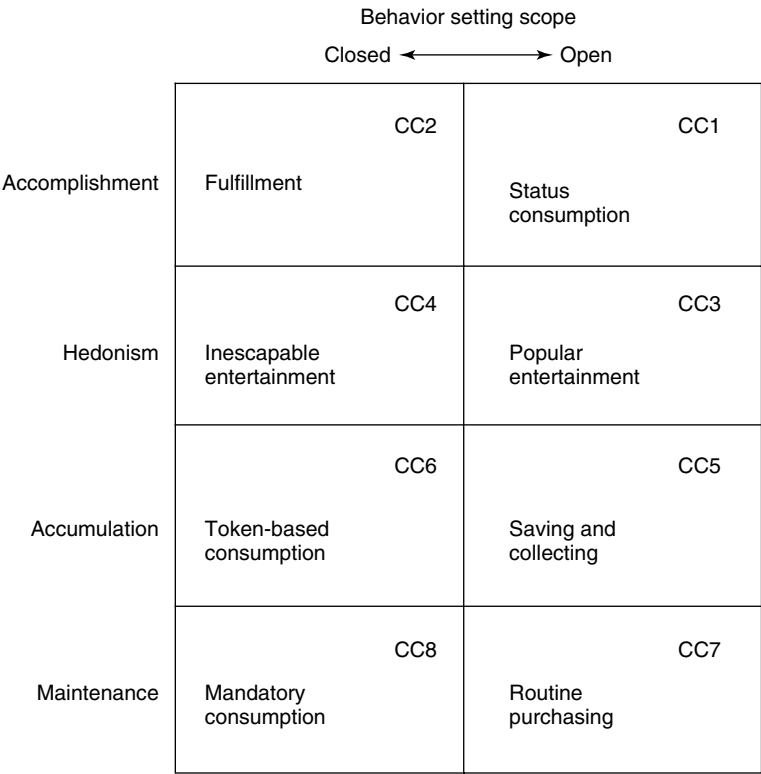

Figure 3 BPM contingency matrix.

listening, or reading for even a short interval is likely to be rewarded. Informational feedback is more obvious on some occasions than others, as when game shows allow the audience to pit their own performances against that of the competing participants, but it is not the main source of reward. Hedonism in closed settings often consists of inescapable entertainment and amelioration. The behaviors in question are potentially pleasurable but may become irksome because they are unavoidable. Consumption of these products and services may be passive rather than active. An example arises when long-haul airline passengers purchase meals and movies along with their travel. The meals are usually consumed, like the in-flight movies, which follow them, without alternative. The setting, which cannot be other than highly restrictive for safety reasons, is further closed by the pulling of blinds, the disappearance of cabin staff, the impossibility of moving

around the plane, and the attention of fellow passengers to the movie. To try to read or engage in other activities may even invite censure.

Accumulation. In an open setting, accumulation is *saving and collecting*: purchases for which payments are made prior to consumption—installments for a holiday, which can only be taken once the full amount has been paid. Discretionary saving with the intention of making a large purchase once a certain amount has accumulated is also included as are promotional deals requiring the accumulation of coupons or other tokens before a product or service can be obtained. The immediate reward is informational, feedback on how much one has accumulated, how close one is to the ultimate reinforcer. Accumulation occurring in a closed setting may be described, in general terms, as *token-based buying* which also involves

collecting—via schemes in which payment for one item provides tokens with which future rewards are obtained. The points earned by frequent flyers constitute informational reinforcers; some hotels offer gifts to frequent customers who accumulate points on each stay. The setting is relatively closed, because once one becomes a member of the scheme there is an incentive to remain in it.

Maintenance. In an open setting, maintenance is *routine purchasing and consumption* including buying goods necessary for survival as in the habitual purchasing of groceries at a supermarket. Comparatively, few such consumers are brand loyal in the sense of always choosing the identical brand in a long sequence of shopping trips. There is so much choice that the consumer enjoys considerable discretion among versions of the product. Maintenance in closed settings is *mandatory purchase and consumption* and includes consumer behaviors necessary to remain a citizen: the payment of taxes for public goods, payments into pension schemes, payments (as in the United Kingdom) of TV licenses.

RESEARCH

Early applications of the BPM were as an interpretive device; issues central to consumer research were examined not within the usual cognitive framework but from a behavioral perspective: the relationship between consumers' attitudes and behavior, the adoption of innovations, spending, consuming and saving, "green" consumption, and the nature and influence of marketing management were interpreted within the new framework (Foxall, 2009). Most of this work was conducted within an ambience of testing out behavior analysis by comparing it with the conventional information processing accounts of consumer choice, a desire to promote a clash of competing explanations. Four strands of later research exemplify the empirical testing of the model: the prediction of consumers' emotional responses to retail and consumption environments, the application of matching and maximization techniques to consumer choice, the analysis of consumer demand (behavioral economics), and experimentation.

Emotional response. The first aim was to test the model as a whole, to understand whether (and if so how) the three structural variables of setting scope, utilitarian reinforcement, and informational reinforcement interacted. Eight empirical studies conducted in a variety of cultural settings employed a tripartite classification to emotion based on Mehrabian and Russell's theory of environmental psychology in which the central emotions are pleasure, arousal, and dominance. Measures of these emotions were hypothesized as predictable in consumer contexts defined by the BPM, so that utilitarian reinforcement was expected to generate pleasure, which implied satisfaction and utility; informational reinforcement to be associated with arousal, which reflects behavioral feedback; and the scope of the consumer behavior setting would correspond to dominance, i.e., being in control. The results of this work confirm the predictions (Foxall, 2005). The expectations of a larger pleasure score for higher utilitarian reinforcement; similarly, a larger arousal score was found for greater informational reinforcement; and a larger dominance score characterized a more open consumer behavior setting scope. The results indicate that by using the pleasure, arousal, and dominance measures as predicted verbal responses to the consumer situations defined by the BPM contingency matrix, it is possible to make useful predictions of consumer behavior.

Matching and maximization. *Matching* is the tendency of animals and humans to distribute their responses between two choices in proportion to the patterns of reward programmed to be contingent on each choice. The key dependent variable is not the single response that needed contextual explication in terms of a single contingent reinforcer: it was the relative frequency of responding, which he or she explained by reference to the relative rate of reinforcement obtained from the behavior. Animals with two opportunities to respond (pecking key A or key B), each of which delivers reinforcers (food pellets) on its own reinforcement schedule, allocate their responses on A and B in proportion to the rates of reward they obtain from A and B. This phenomenon has been replicated in numerous species including humans

and has found applications in behavior modification and organizational behavior management, to name but two relevant fields. In particular, it provides a framework for the behavioral analysis of consumption. The phenomenon is particularly well researched in contexts that require an individual to allocate a limited period between two choices, each scheduled to produce reward at a different rate.

Most choices for human consumers require the allocation of a fixed income between alternative choices, each of which exacts a different monetary sacrifice. In this case, responses take the form of surrendering money in varying amounts, while the reward is the receipt of a fixed amount of the good in question. Price is the ratio of units of money that must be exchanged for units of the good. Both matching and maximizing theories make a similar prediction of behavior on such schedules: the individual will maximize by exclusively selecting the schedule that provides the higher return. Studies of animal choice confirm this prediction. The reason is that, given the parameters of matching in the context of consumer choice, where the schedules that govern performance are close analogs of the ratio schedules imposed in the operant laboratory, both maximization and matching theories predict a similar pattern of choice, one that eventuates in maximization and matching by virtue of the expectation that consumers will always select the cheapest alternative when selecting among brands. The expected behavior pattern is, therefore, exclusive choice of the more favorable schedule. Although there is some evidence that this is generally the case, there are frequent exceptions in that consumers sometimes buy the most expensive option or, on the same shopping trip, purchase both cheaper and dearer versions of the same product, something that animal experiments, which demand discrete choices in each time frame, do not permit their subjects. In other words, the marketing system adds complications to the analysis that cannot be anticipated within the original context of the behavioral economics research program. Even behavioral economics research with human consumers in real-time situations of purchase and consumption (token economies and field experiments) have not been able to incorporate such influences on choice as a dynamic bilateral

market system of competing producers who seek mutually satisfying exchanges with consumers whose high levels of discretionary income make their selection of suppliers not only routine but also relatively cost free. Behavioral economics experiments with human consumers have at best been able to incorporate only a portion of the full marketing mix influence on consumer choice. It has typically been possible to employ price as a marketing variable but not the full panoply of product differentiation, advertising and other promotional activities, and competing distribution strategies, which are the dominant features of the modern consumer-oriented economy. Moreover, because it is the marketing mix, rather than any of its elements acting in isolation from the rest, that influences consumer choice, such experiments have been unable to capture the effect of this multiplex stimulus on purchasing and consumption.

Our analyses found that brand competition was generally marked by ideal matching, while product choices, as demonstrated here by wine and cola purchases by some degree of under-, over-, or antimatching. Relative demand curves were generally downward sloping (Foxall *et al.*, 2007). Consumers maximized by purchasing the least expensive of the brands composing their considerations sets. Where there were exceptions from the predictions of matching and maximizing theories, they occurred for reasons peculiar to the marketing context: first, because the composition of consumers' consideration sets often meant that their selections were among premium priced, higher quality brands, or at least those more highly differentiated through promotional activity, rather than among all of the brands that made up the product category.

An interesting outcome of the application of matching theory to consumer choice is the finding that brands can be defined in terms of their substitutability, while product groupings and categories whose members are independent or complementary are indicated by under-, over-, or antimatching present further evidence on this. We benefit here from making a distinction between utilitarian and informational or symbolic reinforcement, which goes beyond the usual distinction between primary and secondary reinforcers. In the case of brands, it is inevitable that they will tend to be substitutes in so far as

they are functionally similar (almost identical in terms of physical formulation), that is, in terms of utilitarian reinforcement, and complements in so far as they are differentiated by branding, that is, in terms of informational reinforcement or social symbolism. Branding is an attempt to reduce the perceived substitutability of brands by altering their value to the consumer on the basis of their social significance (e.g., increasing the status of their owners and users) or psychological significance (e.g., enhancing the self-esteem of those who own and use them).

The *pattern of reinforcement* (the pattern of low-to-high utilitarian reinforcement and low-to-high informational reinforcement produced by buying or using a product) is an analytical category that takes the place in interpretive behaviorism occupied by that of the schedule of reinforcement in the experimental analysis of behavior. Because patterns of reinforcement differ and because informational reinforcement increases the complementarity of brands within a product category, nonprice elements of the marketing mix come to the fore. The study of brand choice indicates that the multidisciplinary of behavioral economics can usefully be extended by the inclusion of results and perspectives from marketing research. Behavioral economics is supported by the research in that its analyses and conclusions are shown to apply to human consumers in situations of free choice; behavioral economists should appreciate, however, the conclusions of marketing researchers to the effect that most consumers are multibrand purchasers, and that marketing considerations other than price influence choice. Marketing researchers may need to take note of the import of price differentials in brand choice. The behavioral mechanism of choice that underlies the molar patterns of consumer choice depicted here appears to be momentary maximization of benefit, a result that is consistent with melioration or overall maximization. However, the lesson of the research is that brand choice is reinforced by two sources of reward, *utilitarian*, which derives from the functional benefits of the good, and *informational* or *symbolic*, which derives from the psychological and cultural meanings, which goods acquire through their participation in social interactions and, by

derivation, through advertising and other means to branding. The recognition of both sources of reinforcement is the key requirement for both marketing researchers and behavioral economists.

Consumer demand analysis. The point of the discussion of pattern of reinforcement and plasticity of demand is not to dismiss such stalwarts of economic analysis as elasticity of demand. Rather, having established the usefulness of the former types of interpretive construct to consumer behavior analysis, the aim should be to operationalize them and relate them to the standard constructs. This has been one of the tasks of work on consumer demand analysis within the BPM context. Much of the work on demand analysis has involved comparison of the buying patterns of consumers grouped by their predominant purchasing of brands having specific patterns of informational and utilitarian reinforcement.

Observed decreases in the quantity bought with increases in prices, indicated by negative elasticity coefficients, may be associated with different response patterns by different groups. The tendency to buy larger quantities when prices are lower may be related to one or more of the following three patterns: (i) buying larger quantities of a product when its price was below its usual, average, price rather than when its price was above its average price (i.e., intra-brand or absolute elasticity); (ii) buying larger quantities when buying brands belonging to cheaper, lower informational levels than when buying brands belonging to more expensive, higher informational levels (i.e., informational interbrand or relative elasticity); and (iii) buying larger quantities when buying brands belonging to cheaper, lower utilitarian levels than when buying brands belonging to more expensive, higher utilitarian levels (i.e., utilitarian interbrand or relative elasticity). These phenomena have been investigated in two studies, employing different sets of consumer panel data, which have borne out these extensions to matching analysis in the context of consumer choice.

The possibility of combining matching and elasticity of demand analyses has led, most recently, to the testing of an equation that

relates amount spent to quantity bought, utilitarian reinforcement obtained, informational reinforcement obtained, and price paid (which detects promotions). The results strongly support the view that economic demand is influenced not only by the amount purchased but by the variables posited by the BPM – utilitarian reinforcement, informational reinforcement, and aversive consequences – all of which can be shown to influence amount spent (Foxall *et al.*, 2007; special issue of JOBM, 2010).

Experimental analyses. Numerous studies in the experimental analysis of behavior are relevant to the development of consumer behavior analysis (see, *inter alia*, Foxall, 2002). However, several recent approaches to the experimental analysis of consumer behavior are of particular interest to the progress of the model and research program. The first is the use of simulated shopping malls to test predictions of matching theory in a consumer context. A series of experiments investigated the influence of various marketing elements (e.g., price and service level measured in terms of delay) on the spending behavior of buyers of consumer products. This work is significant not only for its contribution to consumer behavior analysis but also for its insights into the nature of economic psychology, that is, the manner in which the all-too-often-separated disciplines of economics and psychology, and biobehavioral consumer research might be integrated. The integration is achieved in this case through foraging theory. Although it is only one of a number of important outcomes of this kind of investigation, the finding that the price of a product may be viewed as a temporal factor by which foraging may be understood is valuable for further research that treats temporally extended consumption by humans in terms of foraging (see special issue of JoEP, 2003).

The constant need in experimental work that is designed to have some impact on the interpretation of complex behavior is to move gradually closer to empirical investigations of choice that permit field experimentation; in this way, the rigor of experimental manipulations and the links with the principles of behavior analysis can be retained while the focus of research more closely resembles the kinds of

day-to-day behavior exhibited by consumers in natural settings. An interesting approach to this is found in experimental work on the influence of the base price of products on the amount of time prospective consumers spend on search. Observation of consumers during the prepurchase phase of their purchase sequence not only permits in-store methodologies to be evaluated in the context of consumer behavior analysis but also yields the result that search behavior is more extensive for higher-priced items. In-store experimentation within the consumer behavior analysis framework has also been undertaken, as well as simulated store choices to test the effects of both utilitarian reinforcement and informational reinforcement on consumer preference (JOBM, 2010).

DEVELOPMENT

The original aim of the research program – to ascertain the epistemological status of a radical behaviorist model of consumer choice – has been fulfilled. Not only is such a model feasible, it has provided unique interpretations of consumer behavior and permitted the prediction of such aspects of consumer choice as brand and product selection. In addition, it has explained such behaviors to the extent of identifying the contingencies that shape them: both utilitarian and informational reinforcement, and the scope of the consumer behavior setting. Wider aspects of the explanation of consumer behavior have not proved amenable to this kind of theorizing, however. Such features of behavior as its continuity and its relationship to the personal level of explanation including subjective experience require the use of intentional language and this implies a different mode of explanation from the extensional approach on which radical behaviorism is based (Foxall, 2004b). The use of the BPM as an interpretive device is also enhanced by the incorporation of intentionality. This does not mean that the original formulation of the model is superseded: it presents a means of predicting and potentially influencing consumer behavior that is not available from other sources. And it fulfills the expectations of a model of consumer choice that radical behaviorism itself would entertain. But the more general demands of consumer

research as a social science can be implemented by the development of intentional and cognitive versions of the model (Foxall, 2007). The main point of these developments is to ascertain the nature of intentional and cognitive explanations of consumer choice respectively, a program that parallels the original aim with respect to behaviorist explanation. As a part of this quest, the application of the BPM to new areas such as intertemporal decision making, compulsion, impulsivity, and addiction, and the nature of the marketing firm continues apace.

ACKNOWLEDGMENT

The author is grateful to other key players in the research program who include Erik Arntzen, Asle Fagerstrom, Donald Hantula, Victoria James, Mike Nicholson, Jorge Oliveira-Castro, Sarah Xiao, Valdimar Sigurdsson, Teresa Schrezenmaier, and Mirella Yani-de-Soriano.

family life cycle

Catherine A. Cole, Dhananjay
Nayakankuppam, and Jayati Sinha

The family life cycle (FLC) emerged as a fundamental marketing concept in the 1950s. Subsequent research on the concept addressed two questions: (i) how many different stages are there in the FLC? (Wells and Gubar, 1966; Murphy and Staples, 1979; Gilly and Enis, 1982; Du and Kamakura, 2006, 2008) and (ii) how do stages in the FLC affect household expenditure, savings, and the mix of products consumed? (see Redondo-Bellon, Royo-Vella, and Aldas-Manzano, 2001 for a review).

For managers, the FLC concept has obvious practical appeal. Stages of the FLC often replace the chronological age of the head of the household as a useful segmenting variable because households within the same FLC stage spend money in similar ways, while households in different FLC stages spend money in different ways. Furthermore, because the proportion of households at different FLC changes across time in predictable ways, the FLC stage can be used as an independent variable in models forecasting primary demand for certain products such as day care or food consumption at home.

However, we suggest that there is a need to better understand the theoretical underpinnings of the FLC model. If the concept is merely an agglomeration of a set of correlated demographic variables, it has little theoretical appeal – its value mainly lies in collapsing a large number of variables into a smaller set, thereby making it more practical and useful. Thus, differences in consumption across different categories formed through the agglomeration of these demographic variables might reflect cohort effects, or shifts in consumption patterns as a function of changing circumstances (for e.g., childcare consumption, and perhaps minivan purchases, are obviously precipitated by the birth of a child). A more interesting question might be to examine shifts in consumer processes as a function of the life cycle. This is an important issue because it is not just circumstances that change and dictate consumption – there are also real social changes brought about in consumer decision processes and these could dictate consumption in much more subtle

and powerful ways. More importantly, these changes are not obvious and could thus result in counterintuitive effects. For example, could the preferences of children influence the preferences of parents, and vice versa?

We start by providing a review of the extant literature on the consumption life cycle. We then review criticisms of this concept. We also propose a framework that might be useful in examining how life cycle might influence consumer processes. Finally, we report briefly on one study from our labs in which we studied how children might influence parent preferences and how household environmental variables (such as parenting style) may account for heterogeneity in preferences among households at the same stage of the FLC.

THE CURRENT HOUSEHOLD/FAMILY LIFE-CYCLE MODEL

The assumption underlying the current FLC model is that family changes (marriage, birth of children, breakup of marriage, etc.) impact both the income and the expenditures of households. On the basis of variables such as age and labor activity of the household head, marital status, and age of youngest child, we can classify families into different stages. The stages of the FLC remain at heart a multidimensional variable resulting from combining other unidimensional ones.

Stages of the FLC. Conceptually, the FLC has evolved over time, primarily through increases in the number of stages and through increases in the flexibility of households in moving between stages. The early years established the conceptual bases of the FLC, utilizing family composition as the organizing theme. Starting in the 1940s and 1950s, the FLC models incorporated new variables as further stages were added to the model. In the more recent literature, FLC models have evolved away from the notion that households pass through an orderly progression of stages (Wells and Gubar, 1966) to the notion that households pass back and forth between stages in a more disorderly pattern (Gilly and Enis, 1982).

Table 1 summarizes the life stages of four prominent models. Wells and Gubar's (1966) model utilizes the criteria of marital status, age of

head of household (HH), age of youngest child, the presence of dependent children, and whether the HH is part of the labor force. The model identifies nine consecutive stages through which an individual passes: bachelor, newly married couple, full nest I–II–III, empty nest I–II, solitary survivor in labor force, and solitary survivor retired.

Murphy and Staples (1979) propose 14 stages linked by multiple paths based on marital status and presence of children. Murphy and Staples (1979) sought to incorporate nontraditional families in response to the evolving family unit. The model considered new classification variables, such as adding the category divorced in marital status and parsing some of the other variables in a more fine-grained manner (e.g., HH age was divided into three bands as opposed to the two in the Wells and Gubar model). This model allowed the age of the children to be classified as (younger than 4, from 4 to 12, and between 13 and 18) to allow sub-stages. The modifications reduced the number of nonclassifiable households to less than 20% in the United States and less than 30% in the United Kingdom.

The Gilly and Enis (1982) model, which includes 13 stages, incorporates nontraditional unmarried cohabiting-couple households and remarriages. Like the Murphy and Staples (1979) model, the Gilly and Enis model is not a single sequence model. Instead, households can move in both directions along various routes. This model represents most HHs since it excludes only 2.8% on the same data of the US Bureau of Census. Wilkes (1995) proposed a 15-stage hybrid of the Wells and Gubar and the Gilly and Ennis typologies.

Du and Kamakura (2006) empirically developed a 13-stage model, which is summarized in Table 1. Instead of a priori defining stages, they empirically identify life stages using a hidden Markov model on household data that include characteristics such as marital status, age, and employment, and information about household size including the number of other adults and the presence of children at different ages. One interesting variable that emerges in their life-stage characterization is whether the household has children in college. Intuitively, this variable should influence household consumption because tuition often represents a major

household expenditure. The data, supporting the life-stage model, were collected from a panel of approximately 8000 households in the United States that were tracked annually from 1968 through the present.

Ability of the FLC to predict consumption. Evidence is accumulating that household/FLC stage affects both the size of the consumption budget and household spending priorities for a broad variety of categories including home ownership, entertainment, energy, and other expenditures (Lansing and Morgan, 1955; Wells and Gubar, 1966; Fritzsche, 1981; Schaninger and Danko, 1993; Wilkes, 1995; Redondo-Bellon, Royo-Vella, and Aldas-Manzano, 2001; Du and Kamakura, 2008). While the reports are too numerous to review extensively, we summarize a few findings. Lansing and Morgan (1955) as well as Wells and Gubar (1966) report that income, expenditures on durable goods, assets, debts, and subjective feelings about financial position differ at different life-cycle stages. Fritzsche (1981) reports that after controlling for income and the number of people in the household, young singles in the Wells and Gubar (1966) FLC classification consume less energy than households at any other stage of the FLC (except for gasoline). Du and Kamakura (2006) analyze discretionary spending across a wide range of expenditure categories. They find that the lowest levels of expenditures are observed for older households with single, divorced, or widowed heads, while the highest are observed for large households with children. They also find allocation differences across households. For example, the top tax- and rent-paying FLC stages are households (single/divorced or young couples) with no children. In summary, there are budget and budget allocation differences across the FLC.

Criticisms of the FLC concept. While much research has verified that FLC is a discriminating variable of consumption and expenditure in a wide range of products and services, there are a number of shortcomings. There is considerable uncertainty about the generalizability of these models. They require frequent updating in the face of social trends that change the dynamics that presumably underlie the different

stages. Further, these models have been developed primarily within the US context and are difficult to apply in other countries with different social contexts. For example, Redondo-Bellon, Royo-Vella, and Aldas-Manzano (2001) present plausible reasons for modifying the model for the Spanish environment and develop a model with 11 stages. Wells and Gubar (1966) note that these models may not generalize across social classes because, as sociologists have noted, there may be differences in consumption goals. Finally, stages of FLC may not affect consumption of all products and services.

Other problems with the concept include the observation that no two investigators have yet agreed on the numbers and types of stages. This makes comparing the results from one study with those from another difficult. Additionally, within a single study, the researcher often has difficulty defining categories. If they are defined too narrowly, they will include a very small portion of the respondents, but if they are too broad, they will squeeze everyone into a few categories. Most models do not cover all possible types of families, nor are the identified types of families always mutually exclusive. For example, the Wells and Gubar (1966) model does not

include household with children older than 17, single people older than 44, or widows with children living at home. Similarly, the Murphy and Staples (1979) model excludes families with children aged above 18, single parent households with a nondivorced parent, and those over 64 living with their children. The Gilly and Enis (1982) model treats cohabitating and married couples as the same, although their consumption patterns may differ.

Additionally, in all the models, older adults are typically lumped together in one or two stages depending on marital status. However, this categorization may mask substantial differences in the older population (those still working, living independently vs those supported by assisted living) that may account for differences in expenditures. Also, these models often do not incorporate the labor force participation of both partners.

Additionally, Commuri and Gentry (2000) raise the point that the most interesting changes in consumer behavior may be observed as households move between stages, not once they reach equilibrium in a stage. Finally, because most research on the FLC uses cross-sectional rather than longitudinal research, cohort effects may explain the observed pattern of results.

An overall problem is the focus on outcome (decisions) rather than processes (decision making). On the one hand, researchers frequently check whether the FLC model does better in predicting outcomes than socioeconomic variables such as size of the household, and characteristics of the main wage earner such as education level, job status, age, and income (Redondo-Bellon, Royo-Vella, and Aldas-Manzano, 2001). However, the models have neither identified underlying mechanisms, which explain how families make decisions, nor have they identified how these mechanisms might change across the FLC to explain different outcomes. In other words, there is little evidence suggesting that the FLC stage determines consumption.

PROPOSED NEW MODEL

Figure 1 contrasts the current and a proposed new FLC model. We propose a new model based on the following linkages: changed circumstances → life-cycle stage → (information processing, memory, attitudes) → behavior → consumption.

Because most people grow up in a family and continue as adults to live in social units, we believe that families have a pervasive influence on consumer behavior. We think that research in this area should shift from identifying characteristics of different life-cycle stages and consumption outcomes to analyzing how life-cycle stage affects the decision process.

Our proposed model suggests questions regarding a variety of interesting factors: how does life-cycle stage affect information processing, memory, attitudes, and behavior? For example, one difference that might emerge between different household types is the time pressure felt. It would be reasonable to predict that increases in the time pressure felt would reduce the amount of information processing for major household purchases. These changes in the time pressure felt might affect memory, attitudes, behavior, and consumption outcomes. Thus, in this example, the underlying variable of interest is not so much the stage of the FLC, but the time pressure felt by members of the household.

In the next section, we narrow down on a specific topic: the influence of college children on parents. Typical models of the FLC minimize this flow because the adult children are no longer living at home.

EXAMPLE RESEARCH: COLLEGE STUDENTS' INFLUENCE ON THEIR PARENTS' CONSUMPTION BEHAVIOR

The study we describe represents part of a larger effort to investigate how adult children “socialize” their parents, which represents a twist on traditional socialization theory, because we are not studying how adults influence their children’s brand choices but how children shape the choices of the adults. Specifically, we study the amount of attitudinal convergence between adult children and their parents for different

| Current family life cycle model | | | | |

Figure 1 The current and proposed new household/family life cycle model.

brands in different product categories. We expect that attitudinal convergence will vary across different types of product categories and across different types of families.

Product category. In our research, we investigated four different types of products: high-technology products, joint family use products, products used for individual purposes, and fast-moving consumer goods. We expect a family's opinions about brands in the high-technology products and in the joint family use categories to converge the most, but for different reasons. If a product is consumed by a family, then the family will confer about the brand and consumption is likely to be correlated—so there will likely be a convergence of attitudes. If a product is a high-technology product, then we expect the college-age student to influence the older parent—the college-age child is likely to be perceived as having expertise in the category and his/her preferences and recommendations would thus be more influential. However, for products consumed for individual purposes and for fast-moving consumer goods, it is likely that members of the household are less likely to discuss the brand choice and preferences with each other and there will thus be a divergence in family opinions. This leads to H1: attitudinal convergence will be higher for high technology products and for products that are consumed jointly and lower for frequently purchased consumer goods and items consumed for personal use. However, more important for the point we are making (namely, that these effects on attitudes are mediated through social processes), we suggest that this influence of college-age students on parents will surface only in certain kinds of households.

Family environment variables as moderators. Households within the same stage of the FLC may differ on constructs that capture family dynamics, such as nurturance, communication style, and parenting style.

Nurturance. We assessed parental warmth or nurturance using an 18-item scale with five-point Likert-type items measuring the degree to which a parent describes his/her interaction with his/her children as being

warm, affectionate, and encouraging. Thus, nurturance is likely to create an atmosphere where children are more comfortable about expressing their preferences, which could thus influence parents. Thus, while we expect greater attitudinal convergence within families for technology products and joint-consumption products, we expect this to be particularly the case in families high on nurturance (H2).

Communication style. Prior research suggests that communication within the family affects children's influence. We use a communication encouragement scale, which is composed of four five-point Likert-type statements measuring the degree to which a parent believes that children should be free to candidly express their own views and disagree with their parents when they feel like it. Prior research reports that parents scoring high on the communication encouragement scale are more likely to talk to their children about consumer issues. Parents are likely to be exposed to the opinions and attitudes of their children, leading to the greater possibility of influence, depending on the extent to which children are free to express their opinions. Thus, while we expect greater attitudinal convergence within families for technology products and joint-consumption products, we expect this to be particularly the case in families high on communication style (H3).

Parental style. Parenting style refers to a group of attitudes toward the child that influence the emotional climate in which the child is raised. Prior research reports that parental style affects both children's choice of influence strategy and their degree of influence indirectly through children's perceptions of parental power. The scale can be viewed as being made up of three subscales: demandingness, emotional responsiveness, and psychological autonomy granting. The demandingness dimension reflects the extent to which parents direct their children's development through maturity, and expectations, close supervision, discipline, and confrontation when a child disobeys. The responsiveness dimension is the extent to which parents encourage their children's individuality by staying attuned to and supporting their children's needs. The autonomy-granting subscale

reflects the parental attitude toward the child having an independent point of view. Thus, while we expect greater attitudinal convergence within families for technology products and joint-consumption products, we expect this to be particularly the case in families high on parenting style, especially on the responsiveness and autonomy-grating dimensions (H4).

Method. A total of 115 student participants took part in the study for partial course credit. They proceeded to fill out a questionnaire designed to assess their attitudes toward a variety of targets as well as containing scales designed to assess family environment–parenting-style scale. Each student addressed a questionnaire to one parent. This questionnaire assessed the parent's attitudes toward the same targets as well as their assessments of the family environment–scales to measure nurturance and communication style.

Analytic approach. Since the data have a nested design (with attitudes of parents and children toward various brands nested within families), with brands at the lower level (level 1) and family characteristics at the higher level (level 2), we adopted a hierarchical modeling technique. This technique is, in essence, a mixed model incorporating fixed as well as random effects, to incorporate heterogeneity. Thus, attitudes toward any stimuli are presumed to be the result of not only characteristics at level 1 (product category) but could also result from the fact that the attitudes come from a certain social unit with interdependencies. This approach allows us to explicitly test for the hypothesized cross-level interaction, where family characteristics (at level 2) impact attitudes of both constituents (at level 1).

For the purposes of the analysis, a deviance score was calculated for each target of judgment by squaring the difference between the parent and child's attitudes. This represents the degree of convergence in family opinion—that is, the higher the deviance score, the greater the divergence in opinion (or the lower the convergence in attitudes). Thus, the deviance scores for a number of targets are nested within families that vary on the family environment variables. One can then estimate whether there

is significant heterogeneity (i.e., do families differ significantly in their deviance scores across targets?). This separates the variance components across the two levels of analysis. One can then examine whether the deviance is impacted by product category, by family environment variables, and, importantly, by the cross-category interaction that has been hypothesized.

Results.

Brand attitudes. A null model yielded significant heterogeneity across families (estimate = 5.85, $z = 5.59$, $p < 0.0001$) and an intraclass correlation of 0.153, revealing that about 15% of the variance was at level 2 (at the level of the families). Adding the product-type variable yielded a significant main effect, $F(3, 342) = 12.64$, $p < 0.0001$. As predicted in H1, the deviance scores for technology ($M = 1.7$) and joint decisions ($M = 1.8$) were smaller than those for fast-moving consumer goods ($M = 3.7$) and personal items ($M = 2.4$). The next models added the perceptions of influence. Both parent's ($F(1, 1723) = 98.85$, $p < 0.0001$) and children's ($F(1, 1724) = 78.91$, $p < 0.0001$) perceptions of influence yielded main effects. We next proceeded to add the family environment variables.

Nurturance. Consistent with H2, analyses yielded a significant cross-level nurturance X product-type interaction, $F(3, 1719) = 3.29$, $p < 0.02$. This interaction is graphed in Figure 2, and shows that, consistent with the hypothesis, high-nurturance families have more convergent brand attitudes on the target categories than low-nurturance families. Families low in nurturance show little convergence across all categories, while families high on nurturance show a significant convergence in the target categories.

Communication encouragement style.

Consistent with H3, a main effect for communication style, $F(1, 113) = 8.11$, $p < 0.01$, was qualified by a significant cross-level product-type X-communication-style interaction, $F(3, 1719) = 7.71$, $p < 0.0001$. The interaction is graphed in Figure 3 and shows that families that scored high on communication encouragement scale had higher convergence of attitudes toward brands than families that scored low on this scale in the target categories.

Figure 2 Nurturance × product-type interaction.

Figure 3 Communication style × product-type interaction.

Parenting style. The main effects emerged for responsiveness, ($b = -0.85$), $F(1, 113) = 3.26$, $p < 0.07$, autonomy granting, ($b = -1.3$) $F(1, 113) = 10.98$, $p < 0.0001$, and demandingness, ($b = -0.75$), $F(1, 113) = 4.89$, $p < 0.03$. As predicted in H4, these main effects were all moderated by significant cross-level interactions with product type (all interactions significant at least at $p < 0.01$ level). These interactions are graphed in Figures 4–6.

Discussion. Analyses suggest that there is considerable convergence in attitudes within families. This suggests that there are, indeed, theoretically meaningful differences in the social processes

that accompany FLC stages. DINKs (double income–no kids) households, for instance, cannot be subject to the kinds of influence we have just outlined. This suggests that it might be worthwhile trying to explicate the social changes that accompany FLC stages and the impact these have on various consumer processes (information processing, memory, attitudes, etc.).

While it is difficult to parse out the direction of influence (is the convergence due to parents influencing children or children influencing parents) with the correlational data reported here, there appear to be the following reasons to think that children do influence parents' attitudes, at least to some extent. First, the

Figure 4 Parent’s responsiveness × product-type interaction.

Figure 5 Parent’s autonomy-granting × product-type interaction.

pattern of influence across the product types is more suggestive of children influencing parents. For example, the technology items were chosen as those that children would be more likely to have experience in (e.g., MP3 players, computers, etc.). Second, we asked participants for the extent of influence they thought they had on their parents for each of the targets of judgments. Children actually had fairly accurate perceptions of when they had an influence on their parent’s attitudes—that is, their impression was that they were more likely to have influenced their parents’ attitudes on the technology and joint-consumption items than the other categories. Third, the pattern

of moderation by the family environment variables lends further credence to this idea—the family environment variables were chosen as theoretical constructs that would suggest a greater propensity for children to express their opinions about products—this further supports the notion that children were likely to have influenced their parent’s attitudes.

CONCLUSION

We conclude by observing that there are several important directions for future research. First, prior research has identified meaningful parameters to use to classify households into life stages. These variables include demographics

Figure 6 Parent's demandingness \times product-type interaction.

such as marital status, age of the HH, employment status of the HH, and age of children (if any). Future researchers should use available sophisticated methodologies such as the hidden Markov models used by Du and Kamakura (2006) to empirically identify the most common types of households in a market and to estimate the probabilities that a household will follow an expected life path. Such an analysis could, for example, help school districts better predict enrollment trends at local elementary schools. Second, research needs to continue to identify how these emerging FLC stages influence consumption outcomes. However, such work would be enhanced if it were based on theoretically derived hypotheses about why consumption priorities shift across the FLC. Third, more research needs to be directed toward households in transition from one stage to the next stage. Households in transition may share characteristics such as a high degree of uncertainty about consumption priorities. Finally, and perhaps most importantly, more research on group consumer decision making would shed light on the processes that underlie consumption decisions made at each stage of the FLC. It is likely that such research will uncover considerable heterogeneity among families at the same life-cycle stage. Our lab study, for example, suggests that variables related to family

dynamics, such as parenting style, may explain some of the heterogeneity. We believe there are many exciting unanswered questions about how family decision making changes across the FLC.

consumer well-being

Aaron Ahuvia, Crystal Scott, and Elif Izberk
Bilgin

Early measures of consumer well-being (CWB) equated it with a person's quantity of consumption, such that the level of well-being in a society can be summarized by its gross domestic product (GDP) per capita. In the 1960s, this reliance on GDP came under criticism by the social indicators movement, which argued for a more holistic view of human well-being beyond GDP, by including factors such as health, education, and crime rates in measures of social progress (see SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE). This focus on diversifying *objective* indicators of well-being beyond GDP was further augmented in the 1970s by large-scale survey research on *subjective* indicators of well-being (SWB), such as happiness and life satisfaction. Our knowledge of subjectively experienced aspects of CWB increased dramatically in the 1990s as the rapidly growing research in positive psychology and behavioral economics brought attention to subjective well-being in all domains of life.

Income is a good proxy of a person's overall consumption level, and hence a commonly used indicator of CWB. Income, and hence consumption, is strongly linked to objective measures of well-being such as health, longevity, and education. But the link between income and subjective indicators of well-being such as happiness is much weaker and more complex (Ahuvia, 2008a, 2008b). At very low income levels where basic human needs are not met, increases in income produce lasting improvements in happiness. And at all income levels, increases in income produce *short term* increases in happiness. However, at even moderate income levels where basic needs have been met, the relationship between income and *long term sustained* happiness is extremely weak. In general, studies show that differences in income explain between 2 and 5% of individual differences in SWB, thus leaving upward of 95% of the difference between individuals in SWB to be explained by other factors such as genetics, social relationships, and the way people think about the events in their lives.

Why does increased consumption among the nonpoor fail to produce much lasting happiness? Is the problem that consumption just does not work, or is it that most people are not consuming in the right way? Spending money has been shown to produce the most lasting happiness when the money is spent on (i) charitable donations (Dunn, Aknin, and Norton, 2008), (ii) things which help foster social relationships (Lyubomirsky, 2007), and (iii) experiences as opposed to physical objects (Van Boven and Gilovich, 2003), so long as the experience was purchased with the primary goal of acquiring a life experience. Apparently, watching television is not such an experience, as it is negatively associated with CWB (Frey, Benesch, and Stutzer, 2007). Finally, there is also evidence that a good way to turn money into happiness is not to spend it at all, as savings is a good psychic investment (Headey, Muffels, and Wooden, 2008).

CWB is not only influenced by how much people spend and how they spend it, but also by their general attitudes about consumption. Higher levels of materialism are associated with lower levels of SWB (Ahuvia and Wong, 2002). Furthermore, though close social relationships are strongly linked to SWB, just thinking about money puts people in a frame of mind in which they are less inclined to reach out to others or offer others their help (Vohs, Mead, and Goode, 2006).

Marketing, and in particular advertising, has inspired controversy around its relationship to CWB (Klein, 2002; Schor and Holt, 2000). Advocates for marketing stress its role in researching consumer needs and aligning production to meet those needs (see MARKETING'S CORPORATE RESPONSIBILITY AND STAGES OF MARKET DEVELOPMENT). These advocates also emphasize the role of marketing in generating sales, and from them profits, employment, and the other benefits of a healthy economy. Finally, they argue that advertising increases CWB by providing consumers with needed information, and by enhancing the value consumers receive from products by investing the products with symbolic meanings (e.g., coolness, masculinity, etc.) which consumers find desirable. Critics of marketing, on the other hand, argue that marketing decreases CWB by increasing

materialism, creating consumer desires in order to fill them, shifting consumers' priorities away from more rewarding nonconsumer activities, promoting racial and gender stereotypes, and promoting unrealistic norms for physical attractiveness or professional success which lead to disappointment and reduced SWB.

knowledge accessibility

Robert S. Wyer, Jr.

GENERAL CONSIDERATIONS

Definition. Knowledge is accessible in memory if it comes to mind quickly and easily in the course of pursuing a goal to which it is relevant. As such, it is distinguished from *availability*, which refers to the existence of knowledge in memory. The distinction is important in light of the fact that people are normally neither motivated nor able to bring all of the knowledge they have accumulated that is relevant to a judgment or decision they make. Rather, they retrieve and use only a subset of this knowledge that comes easily to mind, ignoring other knowledge that is equally applicable but less easily accessible.

Theoretical formulations of the determinants and consequences of knowledge accessibility depend on the type of knowledge in question. *Declarative* knowledge includes single concepts that are used to interpret individual pieces of information, configurations of attributes that are used in combination as a basis for identifying a stimulus as a member of a more general category, beliefs, and attitudes. It can also include sequences of temporally and thematically related events. Some sequences characterize specific experiences one has had and constitute stories that are retrieved and communicated to others. Other, more general (prototypic) sequences can be used to infer the cause of a new event or to predict its likely consequences. These latter sequences can constitute *implicit theories* about the social or physical world. Other sequences may specify the steps required to attain a particular objective.

In addition, *procedural* knowledge concerns the sequences of cognitive or motor behavior that have been acquired through learning and are performed automatically when the configuration of stimuli with which they are associated are experienced. These procedures can include those that operate on declarative knowledge in the course of attaining a particular objective.

Determinants of accessibility. The accessibility of knowledge in memory typically increases with both the recency and the frequency with

which it has been activated and used in the past. Individuals who search memory for knowledge that is relevant to a goal they are pursuing presumably compile a set of features that specifies the type of knowledge required, and these features cue the retrieval of previously acquired units of knowledge that have the features in common.

If concepts and knowledge have been used recently, they typically come to mind more quickly and easily than other, equally relevant concepts and knowledge. Therefore, they are more likely to be used in attaining a goal to which they are relevant. For example, a person may evaluate a luxury car more favorably if (s)he has recently been asked to judge the aesthetic appeal of a series of paintings (thereby increasing the accessibility of aesthetics-related criteria) than if (s)he has recently been asked assess the speed and memory capacity of a computer (thus activating concepts associated with functional utility).

However, the likelihood of knowledge coming to mind in the course of goal-directed activity is also a function of the *frequency* with which it has been used in the past. Thus, concepts and knowledge that have been used very frequently over a period of time become *chronically* accessible in memory and, in the absence of other considerations, may be applied rather than other, potentially applicable but less accessible cognition.

Underlying processes. The situational and individual difference factors that determine the accessibility and use of knowledge are well documented. However, ambiguities continue to surround the cognitive processes that underlie their effects. These processes depend on both the type of knowledge in question and the theory of memory one assumes.

The processes that underlie the accessibility of declarative knowledge are most commonly conceptualized with reference to a spreading activation model of associative memory (Collins and Loftus, 1975; but see Wyer and Srull, 1989, for an alternative). According to this model, concepts and units of knowledge are represented in memory by nodes and the associations between them by pathways that connect them. When a unit of knowledge is activated (that is, thought

about), excitation spreads from the node at which it is located to other nodes along the pathways connecting them. When the excitation that has accumulated at one of these nodes exceeds a certain threshold value, the knowledge at this node is activated (comes to mind). When this knowledge is no longer thought about, the excitation that exists at the node dissipates. However, it takes time to dissipate entirely. Therefore, if a relatively short period of time has elapsed, residual activation may still exist at the node. Consequently, the knowledge is more likely to be reactivated by excitation that is transmitted to it from other sources (e.g., new stimulus information, or a directed search of memory for goal-relevant knowledge).

These processes govern the conscious use of declarative knowledge in the course of goal-directed activity. They also capture the conscious identification and use of a goal-directed procedure under conditions in which more than one strategy is potentially applicable. However, cognitive and motor procedures are often applied automatically, with little, if any, deliberation. These procedures, which constitute procedural knowledge, can be conceptualized as a set of *productions*, or learned “if [X], then [Y]” rules, where [X] is a configuration of externally or internally generated stimulus features and [Y] is a sequence of cognitive or motor acts that are elicited automatically when the preconditions specified in [X] are met (Anderson, 1983).

Productions can guide the cognitive and motor activity in a large number of situations, ranging from the generation of speech to driving a car or using a word processor. However, the activation of a production depends on the particular set of concepts and declarative knowledge that is accessible in memory at the time and, perhaps fortuitously, happens to be included among the features that compose a production’s precondition [X]. Thus, to borrow an example from Bargh, Chen, and Burrows (1996), experimental participants who fortuitously have the concept “slow,” accessible in memory as a result of thinking about the elderly, are likely to walk more slowly to the elevator upon leaving the experiment.

METHODOLOGICAL CONSIDERATIONS

The effect of knowledge accessibility on judgments and behavior has generally been investigated using *priming* techniques, that is, participants are typically asked to perform a task or engage in activity that requires the use of a particular concept, thus increasing its accessibility in memory. The effects of this activity on judgments and behavior in an unrelated situation are then observed. Furthermore, concepts and knowledge can often be activated subliminally in the course of performing an unrelated task.

However, concepts and knowledge can also become chronically accessible in memory as a result of their frequent application over an extended period of time. Thus, for example, cultural differences in the interpretation of information and the construal of its implications can be a reflection of differences in the chronic accessibility of concepts and knowledge that result from frequent exposure to them in the course of growing up. Although the effects of priming concepts and knowledge on their accessibility in memory can temporarily override the effects of their chronic accessibility, the latter effects are likely to predominate after a period of time has elapsed.

The role of awareness. Individuals are not always conscious of why a piece of knowledge comes to mind, and are likely to attribute it to the type of object they are judging or the decision they are called upon to make. Consequently, when two or more units of knowledge are equally useful in attaining a particular objective, objectively irrelevant factors that influence their relative accessibility in memory can determine which is applied, and this can occur without awareness that the influence has occurred.

In fact, when individuals *are* aware that concepts and knowledge come to mind for reasons that have nothing to do with the stimuli being judged, they may intentionally avoid using them. As a result, the cognitions are less likely to be applied than they might otherwise be. On the other hand, conscious attempts to suppress a concept or unit of knowledge require thinking about the knowledge to be suppressed.

Thus, ironically, knowledge may become more accessible in memory as a result of the attempts to suppress it, and, consequently, it may be *more* likely to be used once active attempts to suppress it no longer exist. Thus, for example, individuals who actively avoid using a person's ethnicity or social status as a basis for judgment in order to comply with sanctions imposed in one situation are more likely to use the stereotype in responding to a different person once the sanctions are lifted (Bodenhausen and Macrae, 1998).

Individuals are normally aware that they are applying certain criteria in arriving at a judgment or decision, but are nonetheless unaware of why they applied these particular criteria rather than others that are equally applicable. However, behavior of the sort that is governed by productions can be activated and applied without awareness of the behavior itself. Thus, as in the earlier example, activating concepts associated with the elderly may stimulate people to walk slowly without awareness of their walking speed. Similarly, if a driver who is on the way to the store happens to think about a meeting she has the next day, these thoughts may activate a product that leads her to wind up in front of her office rather than at her intended destination.

APPLICATIONS

The effects of stimulus information on behavior and decisions can be localized at several stages of processing, including the attention to information, its comprehension, inference, and evaluation, and the generation of an overt response or behavioral decision. The following review of representative research on the effects of knowledge accessibility at each stage of processing provides an indication of the range of phenomena in which knowledge accessibility plays a role. (For a more detailed discussion of this research, see Förster and Liberman, 2007; Wyer, 2008.)

Attention and search processes. *Effects of declarative knowledge accessibility.* When individuals receive specific items of information about an object for the purpose of making a judgment, they may first interpret information in terms of more general concepts that the information

exemplifies. However, information that can be interpreted in terms of concepts that are accessible in memory are likely to be more quickly identified and encoded in terms of them than is information that is less easily interpreted. This selective encoding can influence the judgments that are ultimately made.

The concepts that are accessible in memory are likely to be influenced by the goal that individuals are pursuing at the time. The selective attention to information that exemplifies these concepts can influence judgments of the object to which the information refers. For example, individuals who receive information about a person's behavior for the purpose of deciding whether the person is an extrovert may activate attributes of an extrovert and identify information that exemplifies these attributes, ignoring information that describes attributes of an introvert. Consequently, they are likely to judge the person as more extroverted than might otherwise be the case. Similarly, consumers who are asked to decide which of several products they like most may focus their attention on favorable attributes, whereas those who are asked to decide which they dislike most are more likely to focus on unfavorable attributes. Thus, the first group of subjects is likely to judge the products as a whole more favorably than the second group.

Attributes that happen to be accessible in memory for goal-irrelevant reasons can have similar effects. For example, exposing individuals to news stories that concern either domestic or foreign affairs can affect the criteria that individuals used to assess the performance of the United States President. Similarly, priming concepts associated with either taste or health can influence the criteria that consumers use to evaluate a product they encounter in an ostensibly unrelated situation.

Effects of activating procedural knowledge. Other studies show that the procedures that individuals use to search for information can be influenced by the procedures they have employed in the course of performing other, unrelated activities. For example, individuals who have previously rank ordered stimuli from high to low along a dimension, which requires a consideration of stimuli with high values before stimuli with low values, use a similar strategy

when scanning an array of information they encounter later (i.e., the prices of hotels in a given city, or individual consumers' ratings of a product's quality). Consequently, they make higher estimates of the implications of the information than do individuals who have previously ranked stimuli from low to high (Shen and Wyer, 2008). (This, of course, occurs only when individuals do not have the time or motivation to consider all of the information available.)

Comprehension processes. Effects of declarative knowledge accessibility. When people receive information that can be interpreted in different ways, the interpretation they give to it is likely to be determined by the applicable concepts that are most accessible in memory at the time. Thus, for example, exposing individuals to the words such as "adventurous" or "reckless" in the course of performing an ostensibly unrelated color-naming task can influence the concept they use to interpret information that a person wants to cross the Atlantic in a sailboat and, therefore, can influence the evaluation of this person. Similar effects can occur when the concepts used to interpret the behavioral information are primed subliminally.

Accessible concepts and knowledge can have more general effects. For example, statements that appear anomalous when encountered out of context (e.g., "The haystack was important because the cloth would rip") are given meaning, and consequently are better remembered, by preceding them with a single word (e.g., "parachute"). The word apparently activates a complex body of knowledge that permits recipients to construct a mental picture of the situation in which the statement makes sense.

A consideration of the impact of knowledge accessibility on the interpretation of information increases in importance by virtue of the fact that once this interpretation is made, it is used as a basis for later judgments of the information's referent independently of the information itself. Moreover, this tendency increases over time. For example, priming a concept of hostility may lead a target person to be judged as hostile on the basis of behavior that exemplifies this concept. However, this effect is greater a day after the original information is presented than

it is immediately afterwards. Similarly, once a person has been judged as honest on the basis of information that he told his girlfriend that her hairstyle was ugly, the person is judged as more kind than he would be if this initial judgment had not been made, and this tendency also increases over time (Carlston, 1980).

People's reliance on their interpretation of information rather than the information itself can produce distortions of memory. Research on eyewitness testimony (Loftus, 1975) indicates that individuals who have been shown a picture of an automobile accident make higher estimates of the car's speed if the question they are asked refers to the car "smashing into the tree" than if it refers to "hitting the tree." Furthermore, they are more likely to mistakenly remember that there was broken glass in the picture in the first case. Participants apparently reconstruct a mental image of the accident that is consistent with implications of the verbal description they are given and later use this reconstruction as a basis for their recall rather than the original picture they saw.

The chronic accessibility of concepts and knowledge can also affect the interpretation of information. The accessibility of these concepts can arise in part from the frequency of using them in the course of daily life. Thus, for example, music majors are more likely than physical education majors to interpret an ambiguous passage as pertaining to the rehearsal of a string ensemble rather than a game of cards. However, the physical education majors are relatively more likely to interpret a passage as being about a wrestling match rather than a jail break (Anderson *et al.*, 1977).

Assimilation and contrast effects. Primed concepts are more likely to be used as a basis for interpreting information only when the information is sufficiently ambiguous that the concept can plausibly be applied to it. If the possible meanings the information can have do not fall within the range to which the concept is applicable, the concept may be used as a standard of comparison, leading it to have a contrast effect. Thus, for example, exposing participants to the names of moderately hostile individuals may lead a target's ambiguous behavior to be interpreted as more hostile than it would otherwise be, but exposing them to

extreme exemplars of hostility (e.g., Adolf Hitler) may lead the behavior to be interpreted as *less* hostile than it would otherwise be. Correspondingly, consumers typically judge the price of a product, which is unambiguous, to be less expensive if they have previously been exposed to high prices than if they have been exposed to low prices. Furthermore, this is true even when the primed values are conveyed subliminally (Adaval and Monroe, 2002).

Effects of procedural knowledge accessibility. People may employ different strategies in comprehending information. Some individuals, for example, may have a disposition to interpret information in terms of semantic concepts regardless of the modality in which the information is conveyed. Others, however, may be disposed to construct visual images on the basis of the information even when the information is conveyed verbally. These dispositions, which can be either chronic or situationally primed, can influence the impact of the information. For example, individuals with a disposition to form visual images from verbal information may find it difficult to construct an image of an unfamiliar product and to organize descriptions of its attributes into this image. Thus, they may evaluate the product less favorably than persons who process the information semantically.

Furthermore, individuals with a disposition to form visual images may have difficulty processing information about an object (e.g., a hotel resort) if it is described from different perspectives (e.g., that of someone inside vs outside the hotel) and may evaluate the object less favorably than those who interpret the individual items in terms of semantic concepts without forming visual images.

A second processing style with implications for consumer judgment and decisions concerns the disposition to comprehend information items individually or in relation to one another or the context in which they are found. This disposition, like the disposition to process information verbally or visually, can be either chronic or situationally induced. For example, stimulating people to think of themselves as individuals or in relation to others can be induced by asking them to use either "I" or "we" repeatedly in a sentence construction task.

Once activated, these self-referent processing styles can influence the processing of information in quite unrelated domains. For example, inducing individuals to think of themselves in relation to others increases their memory for the positions of physical objects in a stimulus array independently of memory for the items themselves. It also increases their memory for contextual features of a stimulus array as well as the focal object.

The effects of priming independent versus relational thinking are paralleled by the effects of chronic differences in the accessibility of these thinking styles. North Americans typically think of themselves as independent of others, whereas Asians tend to think of themselves in relation to others. These chronic differences in self-construal, like situationally induced differences, are manifested in more general differences in thinking style (Nisbett, 2003). Thus, when asked to group stimuli (e.g., a man, a woman, and a child), Westerners are likely to group them on the basis of category membership (putting the man and woman together, as both are adults) whereas Asians are more likely to group them on the basis of their relation to one another (e.g., to group the woman with the child because the woman takes care of the child). Furthermore, although Asians and Westerners are equally able to identify and remember differences in the central features of a picture, Asians are more likely to remember peripheral, contextual features of the stimuli as well.

Inference and evaluation. Beliefs. When individuals are asked to report their belief that a statement is true, they are likely to search memory for previously acquired knowledge that has implications for its validity. However, they normally retrieve and use only a small subset of their knowledge that comes to mind quickly and easily. This knowledge may often include a semantically equivalent statement they have encountered at an earlier point in time. However, although individuals often remember having encountered such a statement before, they are less likely to remember where or when they did so. In such instances, they may base their judgment on the statement's familiarity. This, in turn, may depend on the ease with which the statement comes to mind.

Thus, if knowledge bearing on a statement's validity has been encountered recently and, therefore, is easily accessible in memory, individuals may often infer that the statement is true without considering the source of this information. For example, people are likely to judge a proposition to be true if they encountered it in a questionnaire they had completed a few days before. Similarly, they are likely to judge a fictitious person to be well known if his/her name was encountered in a different context 24 hours earlier. Perhaps more interesting is evidence that when consumers have been repeatedly exposed to an advertising claim along with an assertion that the claim is false, they later report this as more likely to be true than they would if they had never been exposed to it at all.

When a previously acquired representation of the statement to be judged does not come quickly to mind, individuals are likely to search for other relevant knowledge that bears on its validity. In doing so, they may retrieve and use only a subset of this knowledge that is most accessible in memory, assuming that it is representative of the larger subset that they have acquired and not considering other information that may be applicable. Thus, to give a simple example, they may report a stronger belief that drinking coffee is desirable if they are asked in the morning (when the knowledge that it wakes you up is easily accessible) than if they are asked late at night (when the fact that it gives you insomnia is more accessible).

Individuals' estimates of the likelihood of an event can often be based on their perception of the frequency of its occurrence and this perception, in turn, may depend on the ease with which exemplars of the event come to mind. Shrum, Wyer, and O'Guinn (1998) provide evidence of this in research on the effects of watching television on perceptions of social reality, that is, individuals typically overestimate the incidence of objects and events in the real world when the events occur frequently on television. Furthermore, this tendency increases with the amount of television they watch. Thus, for example, heavy television viewers are more likely than light viewers to overestimate the incidence of violent crime, the number of lawyers and doctors, and the number of individuals who have swimming pools in their backyard.

The assumption that these effects are mediated by the ease with which instances come to mind is strengthened by evidence that when instances are difficult to generate, they can have a negative effect on judgments that is independent of the number that are actually identified (Schwarz, 2004). Thus, for example, individuals report less favorable evaluations of a product after generating many favorable attributes of it (which is difficult to do) than after generating only a few such attributes (which is easy).

Attitudes. Attitudes toward an object, event, or state of affairs are often inferred from estimates of its desirability. Like beliefs, they can sometimes be based on the subset of knowledge that comes to mind most quickly. Although this knowledge can often include a previously formed evaluation of the stimulus in question, other judgment-relevant knowledge can be retrieved and used as well. To this extent, the stability of an attitude depends on whether the same or a different subset of previously acquired knowledge happens to come to mind each time the attitude is reported. In some cases, a recent behavior that has implications for one's attitude may be retrieved and used independently of other criteria. Thus, individuals who have recently volunteered to advocate a position on an issue may later recall this behavior and infer that they favor the position without considering other attitude-relevant knowledge they have acquired (Bem, 1972).

A major source of information about one's attitude toward a stimulus can be one's affective reactions to it. That is, an individual can have positive or negative reactions to a stimulus as a result of encounters with it in the past, and thinking about the stimulus can relicit these feelings. These feelings can then be used as a basis for evaluating it. However, individuals are often unable to distinguish clearly between the affect that is actually elicited by an object they are judging and the feelings they are experiencing for other, perhaps irrelevant reasons. Consequently, extraneous affect that is elicited by thinking about an unrelated past experience, or by objectively irrelevant features of the situation in which an object is judged (e.g., the weather, or music that happens to be playing) can influence judgments of the object (Schwarz and Clore, 1996). In the product domain, the

affect that is elicited by a picture of a product can influence consumers' evaluations of the product independently of more specific attribute information that they encounter later (Yeung and Wyer, 2004).

Decision processes. The implications of the effects of knowledge accessibility for consumer behavior are particularly evident at the decision stage of processing. Research on these effects has concerned both the criteria that individuals bring to bear on their decisions and the procedures they employ when making these decisions.

Effects of declarative knowledge. When the products that consumers consider purchasing have both desirable and undesirable attributes, their choices can depend on which type of attribute they weight more heavily. Suppose one product has a very favorable attribute but also a very unfavorable one. However, a second has a moderately favorable attribute and a moderately unfavorable one. In this case, consumers who focus on favorable attributes are likely to choose the first product, whereas consumers who are concerned with negative attributes are likely to choose the second.

These dispositions may be either chronic or induced by situational factors that are quite irrelevant to the decision to be made. For example, calling individuals' attention to a discrepancy between their actual self concept and their ideal self appears to stimulate a *promotion* focus, that is, a tendency to think about positive consequences of their behavior. In contrast, calling individuals' attention to a discrepancy between their actual self and standards established by others stimulates them to think about avoiding negative consequences. The latter, *prevention* focus can also be induced by increasing individuals' awareness of their membership in a group, thus activating thoughts about social responsibility and decreasing the willingness to take risks. Once activated, these dispositions influence choice behavior in situations that are unrelated to the situations that gave rise to them.

Cultural differences in the tendency to focus on positive or negative decision consequences have also been identified, that is, North Americans are disposed to focus on the positive

features of choice alternatives, whereas Asians are more concerned about the avoidance of negative features. However, these cultural differences may only be apparent if situational factors (e.g., the language in which individuals are communicating, or the need to give a reason for their choices) increase the accessibility of culture-related norms and values (Briley, Morris, and Simonson, 2000, 2005).

Effects of procedural knowledge. Making a purchase decision can involve three steps: deciding whether to make a purchase, deciding which of several alternatives to buy, and deciding how to implement the purchase (e.g., to pay by cash or credit card). Although these steps often occur in sequence, increasing the accessibility of later steps in the sequence can sometimes lead consumers to apply these steps without performing the earlier ones. For example, consumers may think about how to pay for a product without thinking about whether they actually want to purchase it. Similarly, they may consider which product to choose without thinking about whether they want to buy anything at all. To this extent, activating concepts associated with later stages in the decision process may lead consumers to apply these concepts without performing earlier steps, and this can affect their likelihood of making a purchase.

Thus, for example, consumers who are induced to make a small purchase early in an experimental session are more inclined to make a second purchase later in the session than they otherwise would be. Furthermore, inducing consumers to state a preference for one of two choice alternatives can induce a "which to choose" mind-set that increases their likelihood of making a purchase without considering the option of buying nothing at all. Moreover, this is true even if the preferences they report initially pertain to products that are quite different from the ones considered in their later purchase decision and, in fact, do not have to concern products at all (that is, reporting preferences for wild animals, like reporting preferences for products, can increase the likelihood of purchasing snacks that are on sale after the experiment; see Xu and Wyer, 2008).

Overt behavior. The subset of knowledge that is accessible in memory can influence overt behavior as well as judgments and decisions. Moreover, this influence can occur without awareness. A number of studies by Bargh (1997) and his colleagues provide evidence. For example, individuals who have been primed with concepts associated with rudeness in a sentence construction task are more likely to interrupt an experimenter's conversation with a graduate student in order to return a questionnaire. Similarly, individuals who have been primed with concepts associated with the elderly walk more slowly to the elevator after leaving the experiment. Subliminally exposing Caucasian students to faces of African Americans (who are stereotypically associated with aggressiveness) increases their nonverbal manifestations of irritation when they were asked to repeat a boring task. These and other studies suggest that priming semantic concepts activate a production that elicits overt behavior without awareness.

possessions and self

Russell Belk

The concept of extended self (Belk, 1988) posits that there is first an atomized individual self that radiates out into the world by means of both tangible possessions and other people to whom one feels connected. This notion can be traced to William James (1890) who observed that

A man's Self is the sum total of all that he CAN call his, not only his body and psychic powers, but his clothes and his house, his wife and his children, his ancestors and friends, his reputation and works, his lands, and yacht, and bank account. All these things give him the same emotions. If they wax and prosper, he feels triumphant; if they whither and die away, he feels cast down,—not necessarily in the same degree for each thing, but in much the same way for all (291–292).

Belk (1987, 1988) presents various primary and secondary evidence demonstrating that we regard our possessions as constitutive parts of our selves and that both things and people are commonly perceived as varying in their centrality as components of our self conception. When our key definitional objects are people, we construe the self in a more aggregate way. Thus, our children's accomplishments or setbacks are felt as our own and our parents' behaviors can be a source of pride or shame for us as children. Aggregate extended self provides one mechanism to explain why we are more willing to share with those whom we regard as a part of us ("sharing in") than with others ("sharing out") (Belk, 2010). At a more extended aggregate level it helps to understand why our sports team's, university's, or nation's achievements or failures can bring us pleasure or pain.

A related concept is that of attachment to possessions (Belk, 1992; Kleine and Baker, 2004). Because certain possessions are seen as more central to our sense of self, they are protected more, shared less, cared for better, and mourned more when they are lost or damaged. Even internal bodily organs are less likely to be donated when they are seen as more central to our identity (Belk, 1987). An additional individual characteristic that is related to unwillingness to share possessions is materialism (Belk, 1985;

CONSUMER MATERIALISM). *Materialism* is the belief that having or not having desired possessions is a primary source of happiness or unhappiness in life. Theorized subcomponents of materialism include nongenerosity and possessiveness, both of which help explain why more materialistic people may be less generous in sharing their possessions with others. Ironically, despite materialists' beliefs that possessions contribute to feelings of well-being, those who are more materialistic tend to be less happy and report lower feelings of well-being than those who are less materialistic. Although it might seem that those who eschew acquiring or upgrading possessions in favor of experiences might be less attached to possessions, experiences too can be regarded possessively and as self-extending. This is the case, for instance, when we claim bragging rights to places we have visited and things we have done. And even those who practice voluntary simplicity may be attached to those things they own, perhaps even more than those who have more things, but regard them more superficially. In this sense, a wasteful society of abundance may cause a problem in which we are insufficiently materialistic rather than overly so.

POSSESSIONS AND IDENTITY

It should not be assumed however that possessions reflect on us only in terms of their quantity or monetary worth. Rather, the choice of particular possessions and groups of possessions help to define our lifestyles, group affiliations, and perceived personalities. Because the meanings of possessions are defined socially as well as by marketing in an age of branded and increasingly global commodities, the role of particular possessions in identity and impression formation is a changing one. Fashions, novelty, affordability, and the adoption patterns of others all influence these image-related aspects of possessions. Moreover, it is seldom a single good that provides a recognizable identity, but instead a particular ensemble or constellation of goods allows recognition of coherent patterns that can be interpreted as conveying consumption meanings. It takes a coherent and recognizable set of possessions to make an intelligible statement about our identity. In addition, it is not only

2 possessions and self

ownership of certain things or affiliations with certain people that conveys meanings. If the consumer does not have the requisite knowledge or skill to deploy these goods or interact with these people effectively, their possession or affiliation will fail to allow us to bask in their glory. For example, knowing the right wines to order or having the right acquaintances may not be enough to convey sophistication if the consumer is unable to master a meaningful conversation about viniculture or topics of interest to the people who might otherwise enhance our image by virtue of our association with them.

One important study of favorite self-expressive possessions was a three-generation study carried out in Chicago by Csikszentmihalyi and Rochberg-Halton (1981). The youngest, largely teenaged, generation treasured things that helped them perform (e.g., musical instruments, sports equipment). Their 40- to 50-year-old parents favored things that showed their status or power (e.g., automobiles, gadgets). And their grandparents cited objects that showed their connections to friends and family members (e.g., photographs, gifts from others). While this was a cross-sectional study, other studies have found similar life-cycle differences in the meanings of things as well as the degree of materialism exhibited by different generations (*see* FAMILY LIFE CYCLE). Earlier in the life cycle, possessions may help the infant to define a separate identity from his or her mother and subsequently possessions may act as transitional objects like a security blanket to ease the separation from mother and home. Later in the life cycle, as we prepare for death, there is often an attempt among the middle class of the world to leave a legacy for children via heirlooms and other mementos that hopefully leave a trace of our life behind for subsequent generations (e.g., Price, Arnould, and Curasi 2000).

Because of their functions in potentially creating meaningful identities and links to other people over the life cycle, possessions in a society without fixed and inherited roles also help us to envision and enact different selves. Some of these different selves are situational, as when we don different shoes, clothes, and cosmetics to go to work, go to a play, or go running. But there are other self transformations and possession-related rites of passage that

ease us through transitions related to aging, educational and career milestones, marriage, divorce, parenthood, sickness, mourning, and other changes in status, health, appearance, employment, and social connections. In cultures that value independence and self-determination, our desire for expressing uniqueness may be stronger than our desire for expressing affiliation. But normally, both of these forces shape our behavior and both are manifest in the products, brands, and experiences that we acquire as consumers. In efforts to defy aging or try on new personas we may change wardrobes, visit beauty spas, acquire cosmetic surgery, accumulate travel experiences, or simply change brands.

Because possessions are often central to our identity, the involuntary loss of possessions to theft or disaster is often traumatic. Wicklund and Gollwitzer (1992) theorize that at such times as well as when we otherwise feel a lessened sense of self, we attempt to shore up or reconstitute our identity through acquiring new possessions as an act of symbolic self completion. They found, for example, that MBA students who were less secure about their job prospects were more likely to attempt to compensate by acquiring stereotypical business artifacts like new shoes and suits, expensive pens, and attaché cases. This can be seen as a case of trying to improve the image conveyed by the extended self and what we have rather than by what we do or the person we are in some deeper sense.

One approach to understanding the role of possessions in identity is to ask people to describe themselves. Although there are cultural differences in the responses people give to this question, in the West it might be common to list our name, age, sex, occupation, religion, and hometown first. But after that we might begin to list our consumption interests (e.g., musical tastes, sports allegiances, recreational preferences) and the family and friends with whom we identify (Belk, 1987). Maffesoli (1996) has suggested that the contemporary equivalents of tribal affiliations are the “brand tribes” with which we identify (*see* BRAND COMMUNITY). Thus, we might identify ourselves as being a member of the “cult” of Macintosh, a “Red Devil” supporter of Manchester United Football Club, a Phish Phan, or a Harley Davidson motorcycle rider. We may also display these allegiances through

decals, signature clothing, and tattoos so that our affiliations are evident even in contexts where the focus of our loyalty is absent.

More subtly, we often express our moods, lifestyles, religions, personalities, political orientations, and much more by our choices of foods, clothing, homes, automobiles, and other visible consumption choices. There is a behavioral advantage in such attempts at nonverbal communication via consumption choices. Although it would be considered gauche, ostentatious, or crude to introduce yourself to other people by saying such things as "I am rich," "I am adventurous," "I've been to Bali," or "I am looking for love," such messages may be presented in more socially acceptable ways via our visible consumption choices. Nonverbal consumption choices are largely visual, but can also be olfactory, as with perfumes, incense, and cigarettes. Such material expressions of self are enacted largely through our possessions, but they can also involve such patronage choices in areas such as travel (e.g., first class, tour groups), clubs, restaurants, and retailers. And as we invest more of ourselves in digital representations and social networking sites (*see* SOCIAL NETWORKS), identity creation and expression can also include our photographs, web links, taste statements, virtual friendships, and other creative activities made visible to those who visit our Facebook page, website, or blog, as well as to those who receive our e-mails and text messages. With such means at our disposal, the lines of what is socially acceptable have been extended and more and more of our consumption and consumption-related aspirations have potentially become visible to others. Likewise, our network of other people who comprise a part of our extended self has also potentially become more readily apparent.

THE NATURE OF THE SELF

One take on the contemporary self is that we are not only adapting a more malleable extended self that is increasingly external to our physical self and personal traits, but is also more postmodern, fragmented, decentered, and uncertain. Rather than a singular coherent core self that is consistent throughout our lives, in this view, we have multiple selves that we can put on and take off just as we change our wardrobe and clothing.

Although the original conception of the extended self envisioned a central core self with various aggregate levels that are more or less central to our identity as well as various possessions that are also regarded as more proximate or distal to our sense of self, there are other possibilities.

One alternative conception of self that is consistent with the postmodern idea of fragmented selves is that we have a flexible cast of selves that we can call up depending on the situation and the others to whom we are presenting our selves. Thus we behave, dress, eat, and talk differently in a job interview, with our parents, with our children, with our significant other, and with our friends. In a study (Tian and Belk, 2005) of the office place possessions of employees at a high-tech firm in the United States, it was found that their offices, cubicles, and desks were a battleground where conflicting loyalties to the firm and their families were played out. Family members sought to keep themselves foremost in the employee's thoughts through photographs, mementos, children's artworks, telephone calls, e-mails, and other reminders and links. Meanwhile, the corporate culture of the firm made demands for offices uncluttered by such personal items and for some display of the corporate colors, especially when clients came to visit. In addition, the corporation's hold on employees was extended through expectations of employees putting in overtime hours as well as links to them outside of the office via telephone, e-mail, the Internet, pagers, and corporate events like picnics. Thus, rather than forming differing concentric levels of self, the familial and corporate selves engaged one another as adversaries competing for the employee/family member's time and devotion.

Another alternative to conceptualization of self that is more premodern than postmodern is when the nature of the self is more collective and inclusive rather than individual and exclusionary. For example, among the Iñupiaq of Alaska, it is believed that humans and whales share a kindred spirit (Bodenhorn, 2005). The whale gives itself to the people in order to sustain them, but its spirit does not die. Rather it returns again and again to feed the people when they are hungry. As Bodenhorn (2005) explains:

4 possessions and self

What we are talking about here is neither the bounded individual nor performative fragmentary individuals who sound so postmodern. Instead we are talking about being part of a whole that is neither indistinguishable nor separate from it. The cosmology of the whale/human relationship is profoundly unifying (p. 91).

As Belk (1988) recognized, the concept of extended self is both Western and male. To the Inupiaq sense, self is not an individualistic one radiating outward to incorporate more things and people in the environment. Rather, both the people and the environment are part of an integrated whole. The concept of individual ownership and possession is less relevant in this context and the alternative formulation of a giving holistic environment emphasizes the inseparability and interpenetration of people, animals, and the natural world.

THE NATURE OF POSSESSIONS

The nature of possessions seems much more fixed than the existential question of who we are. Yet, notions of property, ownership, and the more general issue of our relationship with the world around us are all less stable and immutable than might initially appear to be the case. For example, just as the concept of self can be more shared and mutual rather than individual, so can the concept of ownership. Communal ownership is a case in point here. What European settlers in North and South America derisively called *Indian giving* was merely a case of Native Americans viewing the land and its resources as jointly owned, or more properly as unowned and unownable by anyone (e.g., Parry, 1986). Similar differences in notions of property and systems of property rights imposed by colonialists have eventually led to conflicts on every continent. Although planned communal societies based on common ownership have often failed and been dismissed as utopian, the vision of communities based on shared ownership has lasted thousands of years. On a smaller scale, the sharing that takes place within families has likely lasted hundreds of thousands of years (Belk, 2010). Infants depend upon parental sharing for their survival. Children typically do not need permission to eat from the family's food pantry, enter the family's

home, or use most of the resources that the family owns. Nor, in using these pooled resources, do they incur a debt that must be specifically repaid. The family in its pooling and allocation of resources comes close to fulfilling Louis Blanc's prescription: from each according to his or her abilities and to each according to his or her needs.

This is not to say that the possessions of families are all held in common. What may have once been the family's joint participation in musical performance through singing, playing musical instruments, and dancing, has subsequently been commodified through subsequent iterations as written music, phonograph recordings, tape recordings, compact discs, music videos, and digital files. In the process, the former family possessions of radios, record players, VCR, and hi-fi systems have become privatized as his/her/their transistor radios, boom boxes, Walkman devices, iPods, and personal computer files. The same is true of many other former family-shared possessions and rituals including rooms, meals, televisions, and cars.

What is true in the family is true in society as well. On one hand, the rise of the Internet and the ability to give and receive digital files while losing nothing and expending little more than electricity has led to an economy in which the majority of music and films are now exchanged either freely or outside of authorized channels in the form of so-called pirated or counterfeit copies. This is truly an economy of sharing rather than proprietary ownership. The same is true of many other things that we regularly give away and consume thanks to the Internet: e-mails, instant messages, websites, bulletin boards, chat rooms, and blogs full of free advice, reviews, recipes, directions, maps, and so on. On the other hand, this free sharing of information has led to a rapid and expansive rise of intellectual property rights legislation designed to preserve the profits and proprietary ownership of music, films, genetic codes, software, and brand property, even (and especially) when it exists in the form of digital information (e.g., see Benkler, 2006). Mark Getty, chairman of Getty Images, has referred to intellectual property as the oil of the twenty-first century. No doubt there will be many more battles in the post-Napster post-Pirate Bay world of

file-sharing and fair-use skirmishes, but meanwhile entities like Google, Wikipedia, Linux, Flickr, Facebook, and others show how a nonproprietary sharing-based orientation toward information can still be an enormously successful business model. In an age of finite and dwindling resources, global warming, and vast inequalities between rich and poor, an economy of sharing looms as a highly enticing alternative to individualistic property and ownership.

Perhaps the world of academic journal publishing offers a model of how sharing, at least in the case of ideas and information, can be a win-win situation. The open model of science that has prevailed since the scientific revolution is based on the premise that science will advance much faster and all will benefit if we publish and share our ideas openly rather than seeking to profit from them. So we submit accounts of our research to journals for which we and others volunteer our reviewing expertise without compensation. We sign over the copyright of our work to the journals that agree to publish it. And we are happy when someone references our work and builds on our ideas. None of this needs to be done out of a spirit of altruism and generosity, for when our work is published and cited, when we are listed as a member of an editorial review board or an editor, and when we send hard or digital copies of our work to anyone who seeks them, we are publicizing ourselves and building our academic reputations. But we have found a way to do this by giving away our ideas and services with the facilitating help of publishers, journals, and web sites who stand to earn a profit in the process. However, even here we can see the beginning of a more proprietary attitude toward the ownership of such ideas. Especially in the sciences such as genetic research, and in certain applied fields like electrical engineering, universities, laboratories, and corporations all seek to protect their inventions through patents, copyrights, and other forms of intellectual property. Scientists are reluctant to publish their work until they are certain they will obtain the patent rights to their discoveries. Thus, even within the hallowed halls of academia, the battle for property rights is increasingly in evidence.

CREATING AND PROTECTING AN INTANGIBLE POSSESSION: THE BRAND

Consumers are not the only ones concerned with creating self meanings through objects in the marketplace. Marketers are critically interested in investing meanings in their intangible brands. The two processes—marketers instilling meanings in their brands and consumers using these brands to create and maintain their self meanings—are interdependent. Moreover, since marketers can only do so much in their attempts to create brand meanings, the completion of this process ultimately depends to varying degrees on consumers to cocreate meanings for the brands they acquire in the marketplace. For example, the image of a model of Nike basketball shoe or Apple iPod depends partly on who the various people are who are first to adopt these objects, their characteristics such as the coolness that others ascribe to them, and what they have to say about their new acquisitions. Therefore, when a marketer attempts to measure the personality or image of a brand, they are partly measuring the image of the consumers who use the brand. And consumers for their part depend on the meanings that marketers have been able to impart to their brands via design, advertising, merchandizing, packaging, pricing, distribution, and other marketing activities. Celebrity endorsers often help in this process as well, as with the successes of Nike and Michael Jordan. It is easy to see this as a case of contagious magic in which the characteristics of the endorser transfer to the brand and from there hopefully to the purchaser of the goods being endorsed.

One category of goods where brand and user image is all-important is luxury goods. In fashions, accessories, handbags, luggage, fragrances, jewelry, and watches, luxury brands can sell for premium prices that can be as much as 10 times more expensive than average brands in these categories, or even more. Exclusivity, quality, and hip and elegant design are a part of the appeal of such goods, as is their exorbitant price and their sometimes limited availability. But their appeal also benefits from the image imparted through the use of celebrities and models promoting the brands, including Tiger

Woods, George Clooney, Chris Jorgensen, Uma Thurman, Kate Moss, Naomi Campbell, and Scarlett Johansson. Contagious magic is no less implicated in luxury goods than it is for more moderately priced offerings. In the case of Louis Vuitton, celebrities are also sought in the art world for design collaborations (e.g., Takeshi Murakami, Stephen Sprouse) and the company also sponsors art exhibitions featuring the work of these and other artists. Such cobranding seeks to draw on the high cultural capital of associating with the world of fine art; something that would be lost for example in sponsoring NASCAR race cars. Luxury goods companies like Tag Heuer that do seek sports celebrity endorsements confine themselves to higher status sports like golf and tennis rather than boxing, for example. Thus just as consumers can enhance their self image by surrounding themselves with popular goods and people, so can luxury brands enhance their images through associating themselves with high-status people, events, and settings.

Given the coproduction of brand meanings by consumers and marketers of luxury goods, one problematic occurrence is counterfeiting. In this case, the much lower prices of counterfeit goods make them available to more people and less-affluent people than comprise the target market of the authentic brands. This creates a dilemma. On one hand, such counterfeit brand proliferation threatens to dilute the brand and reduce its exclusivity. But, on the other hand, to have a luxury brand that is not the object of counterfeiting would suggest that the brand is not sufficiently desirable to warrant imitation. France, the home of many luxury brands including those of Louis Vuitton Moët Hennessy, has enacted legislation that makes it a crime to be in possession of a counterfeit good, with penalties of up to 3000 Euros per item, plus jail time.

On the other hand, brands like Nike, Stussy, Hilfiger, Polo, and DKNY all tolerated, if not encouraged, counterfeit copies of their brands among members of hip-hop culture in New York City. Their reason is simple. Rather than selling an exclusive luxury image, they are selling cool. By associating their brands with rap music and cool kids, they are trying to endow the goods with coolness. Product placements with

popular cool kids in schools are another way that such brands sometimes try to achieve cool status. And another tactic is to use cool celebrities. For example, in a 2006 ad in *Transworld Skateboarding*, Vans promotes a skateboarding shoe called the *Hosoi SK8-HI*. The only copy reads "Very Limited Edition, Available April 1." The ad shows an action shot of skateboarding star Christian Hosoi, for whom the shoe is named. In the same way that Nike was able to exploit Michael Jordan's coolness with the Air Jordan, Vans hopes that Hosoi's cool image will transfer to the shoe. His cool image derives not only from his prominent role in early California skateboard culture, but also from his drug-dealing past. He was imprisoned for three years and was released shortly before the ad ran. He also appeared in the Vans-financed film, *Dogtown and Z-Boys*, about the origins of skateboarding in southern California. Vans has successfully used their early popularity in skateboarding subculture in order to borrow the cool renegade image of skateboarders. They have parlayed this image with products centered on music and cool sports including surfing, snowboarding, BMX wakeboarding, motocross, and supercross. Other shoes have tried to create a cool image by showing ads with cool cars and their owners (e.g., K-Swiss, 310), adult film stars (e.g., Pony), or simply cool-looking people with tattoos and a look of cool indifference (e.g., GBX).

So it can be seen in these examples that the implications of possessions for self image can be commercial as well as personal. By focusing on extended self, celebrity endorsement, cool people, cool settings, and contagious magic, it is sometimes possible to build a brand into an aspirational prop for self image. If William Shakespeare and Erving Goffman are correct, all the world is a stage, and we increasingly rely on ensembles of branded consumer goods in order to try on the various roles that we imagine ourselves playing.

CONCLUSION

It is easy to condemn our reliance on possessions to enlarge our sense of self as being a shallow substitute for the alternative character-based sense of self that presumably hides behind our

façade of consumer goods. Materialism, waste, excessive consumption, and the vicious cycle of striving to have the latest gadgets ultimately prove unfulfilling. And there is much to be said for striving for a simpler material lifestyle and reducing our ecological footprint, especially among those of us who have much more than we need in order to live comfortably. But despite these easy criticisms, possessions also play some very positive roles in our lives. By accumulating certain possessions, we are accumulating visual mnemonic cues to our pasts and potential cues to the meaning of our lives. These material cues often take the form of photographs, gifts, souvenirs, awards, and heirlooms, but they can as easily be a fragment of a song, the whiff or a perfume, or the taste of a particular food like Proust's lime-blossom tea and petite madeleines. At more aggregate levels of self, we also have national monuments, national buildings, flags, and other icons to remind us of our country's past.

Besides looking backward and reminding ourselves of who we are, possessions that we aspire to own can also provide goals that drive us forward in education, career, personal relationships, travel, and other spheres of life. Aesthetic objects can be a source of contemplation, relaxation, and reflection about who we are and what is important in life. We have come to rely on material goods in our rituals of birth, death, marriage, childbirth, and other rites of passage that help us get through life and feel that we are honoring life's sacred moments. Even in our so-called disposable age of ephemeral possessions, it is likely that some of our individual and collective possessions will outlive us. They are sometimes our link to immortality and parts of the trace that we leave behind that will help others remember us when we are gone. For academics, artists, writers, playwrights, poets, filmmakers, craftspeople, builders, cabinetmakers, and others who create, it is their creations that they hope will fulfill this function. For others, it may be any of the many goods that have become embedded in their lives and identities. But regardless of how humble or magnificent the object, the power of possessions lies not only in

their role in our present lives, but potentially in the past and future as well.

attitudes

Paul M. Herr

Any comprehensive treatment of the attitude construct in general and its applications in marketing in particular could easily fill this volume, let alone a single article. Hence, the focus here is to simply identify the construct, describe some of the major stages in its development, and briefly trace its recent history in consumer behavior. Consequently, this article will be far more selective than comprehensive in nature.

EARLY DEVELOPMENT

Throughout this discussion, one is struck by the singular contributions of attitude theorists in social psychology to applications in consumer research. Attitude has long been viewed as a central construct in social psychology, and its role in consumption has been viewed as no less important. Clearly, the ability to elicit from consumers a simple, summary evaluation of goods and services with predictive utility has had strong allure. This appeal, however, is tempered by a history rich with disappointment and debate. Even something as (deceptively) simple as defining the attitude construct (which could also easily fill this volume), not to mention settling debate over the construct's very existence, has filled academic journal pages for many decades. Thurstone's (1928) triumphant claim that attitudes can be measured presupposed both their stable existence and their directive influence on an individual's behavior. Allport's (1935) early definition of attitude continues to guide current thinking about attitude's functional role, as well as spur debate. According to Allport, "An attitude is a mental and neural state of readiness, organized through experience, exerting a directive or dynamic influence upon the individual's response to all objects and situations with which it is related" (1935, p. 810). Central to this definition is attitude's enduring nature, that it is learned through experience, and its directive influence on behavior.

Attitudes' functional role was considered by Katz (1960). His analysis provides compelling reasons why consumers may hold attitudes as

well. Katz suggested that individuals might be well-served by holding stable attitudes about persons and objects in their environment, as useful functions might be served by attitudes. Specifically, Katz identified four functions that attitudes might provide. It is a simple extension to note what each provides the consumers. First, consumer attitudes may serve a *utilitarian* function. That is order and structure are provided by knowing which brands fill needs well and which do not. Likewise, a *value expressive* function is served to the extent a consumer is able to identify which brands and products allow them to best express their central values and who they believe themselves to be. Attitudes of both valences about luxury goods may serve this function. An *ego-defense* function is served by attitudes that protect against damage to the self-concept. Finally, a *knowledge* function allows the holder of attitudes to make sense of an otherwise chaotic and disorganized world; knowing which brands are loved and which are hated.

THE THEORY OF REASONED ACTION

The existence of functionally sound reasons to hold attitudes notwithstanding, prominent failures of attitudes to in fact predict behaviors led Wicker (1969) to suggest that attitudes are epiphenomenal; after-the-fact explanations of behavior, rather than guiding influences, and as such should be abandoned as a scientific construct. Two responses to this attack on attitudes are particularly noteworthy, with respect to both their impact within traditional attitude theory and their influence on marketing. First, with their Theory of Reasoned Action Fishbein and Ajzen (1975) attempted to salvage the attitude construct by (i) redefining attitude as an expected value of the sum of an individual's beliefs about an attitude-object, weighted by individual's evaluations of each of those beliefs, (ii) considering the impact of subjective norms for engaging in attitude-relevant behavior, and (iii) weighting the attitude and subjective norms in predicting the individual's intention to engage in a particular behavior. This development's impact on marketing has been profound. The bulk of academic marketing work, as well as marketing practitioners' work

in attitudes, employs this framework or variants (and more recently, the Theory of Planned Behavior, Ajzen, 1985).

Academic research explicitly studying consumers generally has taken one of two paths: either directly applying the model to consumption settings (and more recently, applying the models to social marketing settings) or engaging in theoretical discussions of the model itself. Representative of the former research is work by Shimp and Kavas (1984) investigating consumer coupon usage and Hansen, Jensen, and Solgaard (2004) examining online grocery purchase intentions.

A great deal of work has investigated modified versions of the Theory of Reasoned Action, as well as questioned the assumptions of and made extensions to the original model. Representative work includes Bagozzi (1981, 1982), Sheppard, Hartwick, and Warshaw (1988), Miniard and Cohen (1983), and Mitchell and Olsen (1981). Central to this work are concerns for the ability of attitudes (affective judgments) to be fully mediated by expectancy-value judgments, the process by which expectancy-value judgments are expected to influence behavior, and how the entire Theory of Reasoned Action model's components is expected to influence behavior.

THE PROCESS MODEL OF ATTITUDE-BEHAVIOR CONSISTENCY

The second significant response to Wicker's (1969) assault on attitudes was a focus on *how* attitudes may influence behavior (Fazio and Zanna, 1981; Fazio *et al.*, 1986). This latter development shifted focus away from "Do attitudes predict behavior?" to a process question "How do attitudes guide behavior?" Moreover, the definition of attitude proposed in this work is conceptually closer to Allport's definition of four decades earlier, but without the necessity that attitudes be linked to behavior. Rather, that link's existence was left as an empirical question. An attitude is considered to be a learned association between a concept and an evaluation (e.g., an affective categorization of a person or an object). Structurally, this may be represented in memory as a link between a node representing the object or person, and its evaluation (e.g., good, bad, and likable.).

Operationally, attitudes may vary in strength, reflecting the strength of the associative link between the object and its evaluation. Relatively weak links reflect relatively weak (or nonexistent) attitudes. Encountering the attitude-object (or its representation) is insufficient to activate the associated evaluation from memory, so the attitude fails to influence behavior directed toward the person or object. Relatively strong links, however, reflect strong attitudes. Simply encountering the attitude-object (or its representation) may automatically activate the individual's evaluation of the person or object from memory. Once activated, the attitude serves as a filter, through which the object and situation are perceived, filtering out attitude-inconsistent information and coloring ambiguous information attitudinally consistent. The individual's behavior is determined by their immediate perceptions of the situation (biased by the attitudinal filter). Attitude-behavior consistency occurs not because of a striving for consistency, or as an end result of a conscious, rational process but rather as a natural end state of the attitude's activation (of which the attitude holder may be wholly unaware). Moreover, for strong attitudes, the activation itself may be automatic and wholly outside the control of the individual (Fazio *et al.*, 1986).

Applications of Fazio's model in marketing have been relatively few, but its applicability is well demonstrated by Fazio, Powell, and Williams (1989). The authors demonstrated that, even after controlling for attitude extremity, product choice was influenced by attitude accessibility. Branded products for which participants held relatively accessible attitudes were more likely to be chosen than products for whom participants held less accessible attitudes. Moreover, prominently positioned products (those placed in the front row of a display) were more likely to be chosen by participants holding less accessible attitudes. That is, their choice was determined by a situational factor (salience of position) rather than an attitudinal factor (strength).

To a considerable extent, attitude's definition has determined the types of models employed in predicting attitude's influence on behavior. While debate over attitude's definition appeared

to be subsiding in the last decade of the twentieth century, the distinction between implicit and explicit attitudes has revived interest in definitional matters, and the debate has been rejoined. This distinction will be visited below.

ATTITUDES AND PERSUASION

A central task facing consumer researchers is to understand the conditions under which product and service communications will produce a sufficiently strong attitude to result in consumer choice favoring a given product or service. During the 1980s considerable research addressed exactly this issue, growing out of Chaiken's (1980) Heuristic-Systematic Persuasion model and Petty and Cacioppo's (1986) Elaboration Likelihood models. The models make largely similar predictions. The ELM (Elaboration Likelihood Model) identifies two "routes" to persuasion; central and peripheral. The central route involves cognitively effortful consideration of the arguments (content) of the communication message. Central processing occurs only when the individual is both motivated and able to think about the message and product. If either is lacking (e.g., the individual does not care about the message or product due to irrelevance, or is distracted, or otherwise lacks the cognitive resources to process the message) the central processing route will be aborted in favor of the peripheral route.

Message-consistent attitudes growing out of the peripheral route to persuasion are based not on the strength of the message arguments, but rather on peripheral cues to message strength, that may be wholly invalid with respect to indicating actual strength of the message. For instance, cues such as number of arguments, length of the argument, communicator attractiveness and confidence all signal that the message may be credible. Without analyzing the actual content of the message, though, a judgment of message credibility is premature. Followers of the peripheral route are insufficiently motivated, or lacking in ability (or both) to effortfully process the content of the message and instead simply rely on the peripheral cues when forming their communication-based attitude.

Central to the ELM is the notion that attitudes changed or formed via the central route will have different effects than will attitudes changed through the peripheral route. Specifically, central route-based attitudes show greater temporal persistence, greater resistance to change, and are better predictors of behavior than attitudes that result mostly from peripheral cues.

The ELM and heuristic-systematic model (HSM) have garnered considerable empirical support, within both the field of consumer behavior and a far-ranging variety of other areas. In a consumer setting, Petty, Cacioppo, and Schumann (1983) exposed participants to print advertisements for a new razor blade. Whether the central or peripheral route would be followed was manipulated by the relevance of the ad to readers. High issue relevance (involvement) was induced by indicating that the razor would be available for purchase in their local market area. It was expected (and confirmed) that this would lead to greater reliance on central processing. Low issue relevance was induced by indicating to participants that the advertised razor would not be available in their market area. Under low relevance conditions, individual's attitudes were most affected by the celebrity status of the product endorsers. In contrast, the quality of product arguments was a more important determinant of the attitudes of individuals exposed to the advertisements under high relevance conditions.

While the ELM and HSM deal primarily with persuasion (attitude change) Fazio's (1990) Mode model addresses how attitudes influence behavior, and reconciles the Theory of Reasoned Action with his own process model. A key distinction between the two models involves the amount of cognitive processing involved in deciding how one will behave in the presence of the attitude object. The Theory of Reasoned Action presents behavior as a reasoned, cognitively cumbersome, and highly deliberative process on the part of the individual. Individuals are said to make systematic use of the information at hand. Salient beliefs about the attitude-object are weighted by their evaluations, summed, and compared with norms to form a behavioral intention. The individual is expected to behave consistently with the intention. Fazio's process

model presents an alternative in which activation of an attitude is relatively effortless and automatic. The attitude colors immediate perceptions of the object in the current situation, which in turn may prompt attitudinally congruent behavior. The MODE model suggests that both attitude-behavior processes may occur, but the antecedents of each differ. Specifically, the more cognitively effortful process occurs only when the individual is motivated and has the opportunity to engage in the more taxing process. If either antecedent is absent, the default value is the relatively effortless process of the Fazio model. In the realm of consumer behavior, the expected differences in attitude-to-behavior processes are relatively straightforward. When consumers are highly involved and have the ability to process, they will likely engage in reasoned action. Such cases include big-ticket items, or purchases of considerable significance in some other regard. Frequent purchases or purchases with small downside potential seem more likely to be driven by the relatively effortless, top-down guidance provided by a highly accessible attitude.

IMPLICIT ATTITUDES

A relatively recent development of some significance is the notion of implicit attitudes and the development by Greenwald and his colleagues of the Implicit Association Test (IAT). Greenwald and Banaji (1995) define *implicit attitude* as "... introspectively unidentified (or inaccurately identified) traces of past experience that mediate favorable or unfavorable feeling, thought, or action toward social objects." (p. 8). This definition grew out of the work in social psychology examining "automatic" (as used by Bargh and his colleagues, e.g. Bargh, 1994) behavior, as well as Fazio's definition of attitude as an association (of varying strength) between an object and its evaluation. "Automatic" behavior is said to proceed in an implicit or unconscious fashion. It is characterized by its spontaneous, unplanned nature, over which the actor has neither awareness nor control, nor, most importantly, awareness of (or conscious access to) cognitions (including attitudes) causally precipitating the behavior. Behavior of this type is at an extreme end of the planned-spontaneous behavior continuum.

The implicit nature of attitudes (and their measurement) is interesting and important, according to Nosek, Greenwald, and Banaji (2007) because, "... implicit cognition could reveal traces of past experience that people might explicitly reject because it conflicts with values or beliefs, or might avoid revealing because the expression could have negative social consequences. Even more likely, implicit cognition can reveal information that is not available to introspective access even if people were motivated to retrieve and express it (see Wilson, Lindsey, and Schooler, 2000, for a similar theoretical distinction for the attitude construct specifically) The term *implicit* has come to be applied to measurement methods that avoid requiring introspective access, decrease the mental control available to produce the response, reduce the role of conscious intention, and reduce the role of self-reflective, deliberative processes" (p. 266).

Greenwald and his colleagues have developed a measure of implicit attitudes (the IAT) that is both widely available and easily used. A description of the test from his website follows:

"In the IAT a subject responds to a series of items that are to be classified into four categories—typically, two representing a concept discrimination such as *flowers* versus *insects* and two representing an attribute discrimination such as *pleasant* versus *unpleasant* valence. Subjects are asked to respond rapidly with a right-hand key press to items representing one concept and one attribute (e.g., *insects* and *pleasant*), and with a left-hand key press to items from the remaining two categories (e.g., *flowers* and *unpleasant*). Subjects then perform a second task in which the key assignments for one of the pairs is switched (such that *flowers* and *pleasant* share a response, likewise *insects* and *unpleasant*). The IAT produces measures derived from latencies of responses to these two tasks. These measures are interpreted in terms of association strengths by assuming that subjects respond more rapidly when the concept and attribute mapped onto the same response are strongly associated (e.g., *flowers* and *pleasant*) than when they are weakly associated (e.g., *insects* and *pleasant*)." (http://faculty.washington.edu/agg/iat_materials.htm)

The IAT measure is not without its critics. Blanton and Jaccard (2008) note that many variables are confounded with associative strength, and influence the IAT, including the similarity between two objects (De Houwer, Geldof, and De Bruycker, 2005), different degrees of familiarity with stimulus items on the IAT (Brendl, Markman, and Messner, 2001), and “salience asymmetry,” of items on the IAT (Rothermund and Wentura, 2004). Reliability concerns with the IAT have also been raised. Steffens and Buchner (2003) found test-retest correlations ranging from 0.50 to 0.62. Greenwald, Nosek, and Sriram (2006) reported average test-retest scores of the IAT across a range of studies of 0.56. Cunningham, Preacher, and Banaji (2001) reported average test-retest correlations over a two week measurement period of 0.27.

Moreover, Han *et al.* (2010) found that the IAT’s susceptibility to extrapersonal (essentially nonattitudinal) associations increases its sensitivity to transient contextual influences (that render both reliability and validity suspect). Specifically, the authors compared the IAT with Olson and Fazio’s Personalized IAT (in which the evaluative labels include “I” (e.g. “I like” or “I dislike”) rather than a general “Like” or “Dislike.” This forces respondents to interpret the stimuli in terms of their own experience, rather than the ambiguous interpretation (either personal or normative) that is possible when a nonspecific label (such as “good”) is used. In the first experiment, the traditional IAT was found susceptible to mindset priming effects. An earlier experience in an unrelated task influenced how respondents disambiguated the IAT labels, and whether they adopted a normative or a personal focus while completing the IAT. Subsequent experiments revealed that scores on the IAT indicated attitude change when it was unlikely to have occurred, and failed to detect attitude change in a situation when all other indications were that attitude change had in fact occurred. In each case, by personalizing the IAT the influence of contextual factors was eliminated.

In spite of predating the formal development of the implicit attitude construct, the MODE model anticipates its relevance and accommodates its existence in consideration of attitude function surprisingly well. This is partly due to

the definition of attitude in both cases as dependent on associative strength, but also due to the MODE model’s explicit accounting for how attitudes are expected to influence behavior. That is, a person’s awareness of the attitude (or its basis) may have little to do with whether the attitude can influence behavior. As discussed previously, of greater import is the strength of the attitude and the motivation and opportunity of the individual to process. When the association between the object and its evaluation is sufficiently strong, evaluations may be activated automatically upon the encounter of an object-relevant stimulus.

The activated attitude’s influence on further evaluative judgments of the attitude-object depends on the individual’s motivation and opportunity to engage in elaborate processing of evaluative characteristics of the attitude-object.

Fazio (2007) notes that the correspondence between implicit and explicit measures of attitudes also depends on the motivation and opportunity of the individual. Specifically, he suggests that since the verbal expression of any object-judgment occurs following the automatic activation of any relevant attitude, such attitude-relevant verbal responses may be influenced by motivational factors as well. Hence, greater correspondence between implicit and explicit measures is expected when motivation to deliberate is low and (or) the opportunity to do so is low. When both are high, additional information is likely to be at least to some extent inconsistent with the attitude indicated by the implicit measure, rendering correlation low.

CONCLUSION

Albeit well-intentioned and within constrained limits successful, the quest for a simple measure of attitudes’ influence on behavior appears all but finished, and for those interested in simple answers, the news is not good. As noted, though, the journey has provided insight into a far more interesting set of questions, and uncovered relations between attitudinal processing and behavior that are both more interesting and important for a far broader range of attitudinal phenomena than the answer to the simpler “Does attitude predict behavior?” question. Specifically, attitude existence, verbal expressions of, formation, strength, change,

resistance to attack, persuasion, conditions under which some kinds of attitudes predict some kinds of behavior for some kinds of people, and attitudes' relations to other constructs have all become substantial areas of investigation in their own right. Each also has much to inform the student of consumer behavior.

implicit consumer cognition

Patrick T. Vargas and Sangdo Oh

Advertisers worry about clutter; they worry about getting their message noticed amid all the other messages aimed at consumers. Some estimates suggest that the average American is exposed to over 3000 advertisements each day. It would be impossible for even the most motivated and patient consumer to wade through all of that information attentively. Fortunately for advertisers, focused attention may not be absolutely necessary. Consumers may be affected by information outside of their conscious awareness. There is a large and growing body of psychological and consumer research demonstrating that people need not intentionally process information to be affected by it. In this article, we offer a brief review of research on implicit consumer cognition.

Implicit cognition (*see* KNOWLEDGE ACCESSIBILITY), more generally, refers to the influence of past experience without conscious recollection or awareness of the influencing experience. For example, consider a classic study of memory (Warrington and Weiskrantz, 1970). Amnesiacs have difficulty with short-term memory. When shown a list of words for study and later asked to recall words from the list, amnesiacs perform substantially worse than non-amnesiacs. However, on certain types of tests, amnesiacs show roughly the same evidence of prior exposure to the studied words as non-amnesiacs. These are implicit tests, in which the memory “test” is presented as a simple task to be completed rather than an explicit demand for conscious recollection, for example, word stem completion: deter_ _ _ could be either detergent or deterrent. Amnesiacs and non-amnesiacs that had recently studied a list of words including the word detergent are more likely to use detergent to complete the stem. Thus, amnesiacs show evidence of prior exposure to the words, at almost exactly the same rate as non-amnesiacs, but only on implicit measures of memory.

Implicit consumer cognition may be defined as the unacknowledged or misidentified influence of prior experience on consumer-related judgment and behavior. In this article, we review research on implicit consumer cognition. We

begin with an overview of implicit measures, with a focus on how they may be applied to marketing and consumer behavior; and then we address implicit processes and effects, including topics such as subliminal persuasion and priming.

IMPLICIT MEASURES OF ATTITUDES

ATTITUDES are central to the study of marketing and consumer behavior. Consumers rarely choose products or patronize services that they dislike, so it is important for marketers to engender positive attitudes. Advertising agency Saatchi & Saatchi conceptualizes brand strength in terms of “lovemarks,” employing ideas like love, respect, inspiration, sensuality, and intimacy. Very often consumers report definitive attitudes toward brands, sometimes positive and sometimes negative. Traditionally, attitudes are measured using explicit, self-report measures, in which respondents indicate on, say 10-point scales, how much they like or dislike an object (semantic differential scales). Other explicit attitude measures present respondents with a series of valenced statements about an object, and respondents are asked to indicate their level of agreement with the statements (Likert-type scales), or select a few statements that most closely match their own feelings (Thurstone scales). However, sometimes research participants may be unwilling to express their true feelings, or, in some cases, they may not know how they really feel about some object. In these cases, researchers have turned to implicit measures of attitudes.

Like implicit measures of memory (described briefly, above), implicit measures of attitudes are presented to research respondents simply as tasks to be completed. Respondents’ performance on the task can then be used to infer their attitudes. In one early consumer study involving an implicit measure, respondents were simply given a seven-item grocery shopping list and asked to make some judgments about the woman who made the list (Haire, 1950). There were actually two versions of the list: one version contained Maxwell House drip coffee, and the other version contained Nescafe instant coffee. The lists were identical in all other respects. Half of the research participants received the Maxwell House version

2 implicit consumer cognition

of the list and the other half received the Nescafe version of the list. Those who received the Nescafe version were more likely to describe the woman who wrote the list as “lazy,” “a poor planner,” and a “bad wife.” These characteristics strongly suggest that consumers had negative attitudes toward Nescafe instant coffee. Implicit measures of attitudes have come a long way since 1950.

Two of the most popular contemporary measures are computer-based and rely on millisecond differences in response times. The Implicit Association Test (IAT, *see* Greenwald *et al.*, 2009) is presented to respondents as a series of classification tasks. Four categories of stimuli are presented sequentially on a computer screen, and respondents must categorize the stimuli as quickly as possible by pressing one of two keys associated with the different categories. Initial trials of a typical IAT involve two categories, for example, good and bad, or fruit and cigarettes. Respondents must press one key if the stimulus is a good word or picture, and another key if the stimulus is a bad word or picture. Some subsequent trials involve all four categories, forcing respondents to pair categories on the keys. For example, one block of trials may require respondents to press one key if the stimulus is either fruit-related or good, and another key if the stimulus is either cigarette-related or bad. A later block of trials will reverse the pairings, requiring respondents to press one key if the stimulus is either cigarette-related or good, and another key if the stimulus is either fruit-related or bad. In this example, we refer to these blocks of trials as consistent (fruit/good and cigarettes/bad) and inconsistent (cigarettes/good and fruit/bad). For most Americans, categorizing the consistent trials would be easier, and faster, than categorizing the inconsistent trials. Average response times for each block of trials can be calculated, and the difference between these times is known as the *IAT effect*. It is really a measure of the strength of an individual's associations between the concepts used in the task. If someone finds it easier to associate fruit/good and cigarettes/bad than cigarettes/good and fruit/bad, we can infer that they have relatively favorable attitudes toward fruit, and relatively negative attitudes toward cigarettes.

The IAT has generated an enormous amount of research. A recent review of the research considered 184 distinct studies involving a total of 14,900 respondents (Greenwald *et al.*, 2009). A meta-analysis of these studies revealed that the IAT was moderately correlated with a wide variety of different behaviors, judgments, and physiological measures ($r = 0.274$). In the domain of consumer preferences (40 studies involving 3257 respondents), the IAT showed a slightly higher correlation with relevant outcomes ($r = 0.323$). Studies of political preference (11 studies, 2903 respondents) obtained average IAT-criterion correlations of 0.483; studies of alcohol and drug use (16 studies, 1718 respondents) obtained average IAT-criterion correlations of 0.221.

A second popular, computer-mediated implicit measure of attitudes relies on priming (*see* Wittenbrink, 2007). Measuring attitudes with priming also involves the sequential presentation of stimuli on the screen, and requires respondents to categorize the stimuli as quickly and accurately as possible. Again, respondents categorize the stimuli using two keys, each assigned to one of the two categories – usually one key for “good” and one key for “bad.” The judgment task is influenced by the brief presentation of an attitude object immediately prior to the task, a prime. Reusing the example from above, a prime (picture of a cigarette or picture of a piece of fruit) would appear very briefly on the screen, and disappear, replaced with a good or bad word. The respondent's task is to categorize that target word. In general, people are faster to categorize the target words when they have been preceded by an evaluatively consistent prime. So, for example, people would be faster to categorize a good word when it is preceded by an image of grapes, than to categorize a bad word when preceded by an image of grapes. Likewise, they would be faster to categorize a bad word when a picture of a cigarette precedes it, than to categorize a good word when a picture of a cigarette precedes it. However, someone who loves cigarettes and hates fruit would likely be faster to categorize cigarette → good and grapes → bad, compared to grapes → good and cigarette → bad. This priming measure has also been used in a wide variety of studies, and

reliably predicted relevant behaviors and judgments. This measure has been shown to work when the primes are presented subliminally – so the procedure can be administered to respondents who are completely unaware of the attitude objects under consideration.

There are dozens of implicit measures in use now, each with different characteristics. Many of these implicit measures do not require millisecond-resolution for response times, and may therefore be easier to use in the absence of dedicated computer software. One such measure is the Affect Misattribution Procedure (AMP; Payne *et al.*, 2005). This measure is procedurally similar to the priming measure, but does not require respondents to categorize target stimuli. In the AMP, respondents are presented with a prime, that is, some attitude object (e.g., grapes or cigarettes), which then disappears from the screen and is replaced by some neutral, abstract stimulus (e.g., a Chinese ideograph). Respondents then have to indicate how much they like the ideograph. Their responses are influenced by the primes. Ideographs that are preceded by pleasant primes are rated as more favorable than those that are preceded by unpleasant primes. This effect occurs even when respondents are explicitly warned that the primes could influence their judgments, and instructed to try to prevent that from happening.

Other implicit measures are even easier to implement, requiring only willing respondents, a pencil, and some paper (*see* Vargas, Sekaquaptewa, and von Hippel, 2007). These measures come in many different forms, and have been used to predict judgments and behaviors, as well. One such measure involves presenting respondents with sentence beginnings, and simply asking respondents to complete the sentence in any way that is grammatically correct. Some of the sentence beginnings are constructed so that they violate or confirm commonly held beliefs, like the belief that Toyota automobiles are very reliable: “Paul’s Toyota broke down ...” or “The odometer on Paul’s Toyota was approaching 150 000 miles ...” Because people have a natural tendency to explain unexpected events, their completed sentences often imply favorable or unfavorable attitudes toward the targets. Thus, someone who had favorable attitudes

toward Toyota might be inclined to try to explain the Toyota’s breakdown (“... because Paul drove like a madman.”), but not the Toyota’s resiliency (“... and he expected it to last for another 150 000 miles.”). Someone with negative attitudes toward Toyota might be expected to show the opposite pattern – explaining sentence beginnings featuring good things about Toyota (“... because Paul was the luckiest guy on the planet.”), and simply continuing sentence beginnings featuring bad things about Toyota (“... and Paul knew he wouldn’t get to the job interview in time.”).

As noted above, implicit measures have typically been reserved for use when explicit attitude measures are not expected to perform well, such as when social desirability concerns would influence respondents to report so-called politically correct attitudes, rather than their true feelings. At least one type of paper-and-pencil implicit measure has also been shown to predict unique variance in behavior, beyond what can be predicted by traditional explicit measures – even when the attitude object under consideration is not a socially sensitive topic. Attitudes are complex constructs, with many different facets, each of which may play some unique role in driving behavior. Implicit measures most likely tap different components of attitudes than explicit measures (Gawronski and Bodenhausen, 2006). Traditional, explicit measures are believed to assess propositional components of attitudes – essentially, these are evaluative statements about some object that are stored in memory, such as, “I believe that Apple is a good brand.” Response-time-based implicit measures are believed to assess stored evaluations that are automatically activated by the presence of some attitude object. A crude example of an automatically activated concept can be seen in the facility with which “butter” comes to mind when someone says “bread and...” Bread and butter have been paired together so often that invoking bread automatically activates the concept of butter. In the same way that bread and butter are linked, many attitude objects are linked to evaluations (e.g., puppies + good). These evaluations may not be consciously endorsed, but they are automatically activated in the presence of the attitude object, and this activation is reflected in

4 implicit consumer cognition

the speed with which someone might categorize rainbows as good following a cuddly puppy prime in a priming implicit measure.

Research on implicit attitude measures is exceptionally fast-moving. In 1995, there were fewer than 10 published articles on implicit attitudes, but just a decade later there were nearly 100 articles published on the topic. It is an exciting area that continues to develop, and is likely to have an increasingly profound impact on consumer research.

IMPLICIT PROCESSES

As noted above, people cannot possibly consciously process all the advertising and marketing-related stimuli they encounter, much less than all the other stimuli they are faced with. A great deal of cognition goes on outside of our conscious awareness. When it comes to consumer cognition, we can lack conscious awareness of (i) environmental stimuli that may influence our behavior; (ii) automatic cognitive processes that are driving our behavior; and (iii) outcomes, including preferences, judgments, behaviors, emotions, and so forth (Chartrand, 2005). In this section, we review additional work on implicit consumer cognition, beginning with the influence of environmental stimuli that are outside of conscious awareness.

Lacking awareness of stimuli. “I saw a subliminal advertising executive, but only for a second,” (attributed to Steven Wright, comedian). One of the greatest obstacles to successfully marketing goods and services is the consumer’s resistance to new information and persuasion (see CHOICE MODELS) attempts. When consumers are aware of persuasive intent, they are much more likely to try to counterargue, disengage, or otherwise refuse to go along with the would-be persuader. From a marketer’s perspective, it would be great to be able to bypass consumers’ resistance to persuasion, and just plant ideas to like and buy specific brands directly in the consumers’ minds. From a consumer perspective, the prospect of marketers bypassing our ability to resist is terrifying – it would be just a short step from mind control.

For these reasons, marketers and consumers, alike, seem to share a fascination with the idea

of bypassing the conscious mind, persuading without allowing any opportunity to resist. This idea ostensibly came to fruition in September 1957, when James Vicary announced that he had used subliminal persuasion to increase popcorn and soda sales. Vicary claimed to have subliminally presented messages (“Eat popcorn” and “Drink Coca-Cola”) during a movie. The messages, presented at 1/3000th of a second, were well below the threshold for conscious perception – moviegoers would not have even realized that they had been commanded to eat and drink. And Vicary claimed that this technique increased sales of popcorn and soda in the theater by 18.1 and 57.5%, respectively. The implications of this “experiment” were profoundly troubling. It would be a few years before *The Manchurian Candidate* was popularized (the book was published in 1959; the film debuted in 1962), but by using Vicary’s technique one could imagine nudging an unsuspecting public to do any number of things – work harder for less pay, vote for a crooked politician, discriminate or even wage war against some unfortunate group.

The public was nervous. Letters and editorials appeared in the news, Congress and the Federal Communications Commission discussed the ethical implications of subliminal persuasion, and the National Association of Broadcasters banned SUBLIMINAL ADVERTISING. The public disquiet turned out to be unfounded. Attempts to duplicate Vicary’s claims were unsuccessful, and in a 1962 interview in *Advertising Age* Vicary admitted that his claim was bogus. He had made the claim in an effort to promote a company in which he was a partner, the Subliminal Projection Company. Despite no solid evidence in support of subliminal persuasion, the concept remained firmly embedded in the public mind.

Several best-selling books promoted the idea of subliminal persuasion, including Vance Packard’s (1957) *The Hidden Persuaders*, and Wilson Brian Key’s luridly titled, *Subliminal Seduction: Are You Being Sexually Aroused by this Picture?* (1973) and *The Clam-Plate Orgy: And Other Subliminals the Media Use to Manipulate Your Behavior* (1980). Surveys reveal that roughly three-fourths of Americans are aware of subliminal advertising, and of those

who are aware nearly all believe it is actually used, and close to half believe that they may be susceptible to subliminal advertising.

The truth about subliminal persuasion is a little more down-to-earth. For one thing, the term *subliminal* is very often misused in the general media. Steven Wright's clever line about a subliminal advertising executive exemplifies this misuse. The term subliminal evokes the limen, which is the threshold, or point, at which a stimulus evokes a sensation. A subliminally presented stimulus is one that evokes no sensation in the respondent; that is, the respondent has no conscious sense of having seen (or heard, smelled, tasted, touched) the stimulus. Mr. Wright would not have perceived a truly subliminal advertising executive. As well, the limen varies among people, such that one person's subliminal stimulus may be another's supraliminal (consciously perceived) stimulus; the limen also varies within individuals, so that stimuli presented at the same level of intensity may evoke a response at some times, but no response at other times. Objectively operationalizing a subliminal stimulus is therefore quite difficult. Most researchers have opted for a more subjective approach, in which a stimulus is considered subliminal if the respondent cannot notice its presentation (even when they are highly motivated to do so, such as when they are offered cash incentives for correctly identifying the presence of a stimulus).

Subliminal stimuli should be differentiated from transformed stimuli, or unattended stimuli. The former are distorted, blurred, or otherwise degraded so as to be less recognizable; the latter may be clearly recognizable, but are not intended to serve as focal points for attention. An auditory example of transformed stimuli might be music in which different lyrics are audible when played in reverse. An auditory example of unattended stimuli is when different messages are played in left and right headphone channels, while the respondent is instructed to attend to just one channel. Many of the examples used in books by Key and Vicary are transformed, or unattended, rather than strictly subliminal; so most of the claims by Key and Vicary are misinformed, at best, and downright misleading, at worst.

Good, solid evidence for subliminal persuasion is scarce, but it does exist. A review of

over 150 mass media articles and over 200 academic papers obtained no solid support for subliminal persuasion (Pratkanis and Aronson, 1992). The articles were seriously flawed in a variety of different ways, making it difficult to infer valid and reliable effects of subliminal stimuli. However, several recent academic articles have offered some evidence that subliminally presented stimuli can have an impact on consumer behavior.

In one study, participants watched an episode of *The Simpsons*. Half of the participants were presented with subliminal primes pertaining to thirst, and the other half were not. Participants who were exposed to the thirst primes later rated themselves as being thirstier than those who were not exposed to the thirst primes (Cooper and Cooper, 2002). In another study, the researchers experimentally manipulated thirst by having all of the participants eat cookies and having half of the participants then drink a glass of water. Next, participants were subliminally exposed to thirst-related words, or words unrelated to thirst. In this study, there was no effect of the thirst prime on participants' self-reported thirst; however, in a fake taste test, participants who were both thirsty and primed with thirst-related words drank the most Kool-Aid (Strahan, Spencer, and Zanna, 2002). In yet another study, researchers experimentally manipulated participants' thirst, and then subliminally exposed participants to a particular brand of beverage or neutral words. Participants who were thirsty and exposed to neutral words expressed no preference for one beverage over another, but those who were thirsty and exposed to the branded beverage showed a marked preference for the brand of beverage that had been subliminally primed (Karremans, Stroebe, and Claus, 2006).

Work on subliminal persuasion continues, but the evidence to date suggests that subliminally presented stimuli most definitely cannot induce moviegoers to get up during a film, go to the concessions stand, and buy a tub of popcorn and a Coca-Cola. Subliminal stimuli seem to be most influential when people are already motivated to engage in some behavior – the subliminal stimuli tend to nudge people further in the direction in which they are already leaning.

6 implicit consumer cognition

Lacking awareness of cognitive processes.

Supraliminal stimuli can also influence consumer judgment, emotion, and behavior. A popular classroom demonstration of this effect begins with a list of words that students are instructed to memorize: ocean, waves, gravity, beach, and moon. In order to prevent students from rehearsing the words (the most common strategy for memorizing a handful of items), the instructor asks students a series of questions and instructs them to answer each question aloud. "Name a brand of automobile." In a crowded classroom, the response is an indistinguishable rumble of different brands. "Name a brand of shoes." Again, the response is an indistinguishable rumble. After a few more questions the instructor says, "Name a brand of laundry detergent." The class responds, almost unanimously, "Tide."

When asked about the surprising unanimity of the Tide response students often volunteer that Tide is a brand leader, or that their family uses Tide, or that it just came to mind. Usually, at least one student will also make the connection between the list of words and the conceptually related brand name. The word list serves as a prime, increasing accessibility of the concept of tides. When an opportunity to use the accessible concept arises, many students will do so. In theory, the laundry detergent brand "Cheer" could be elicited by using the words stadium, fan, mascot, game, and team. Priming is an example of a case where people are aware of some stimulus, but generally unaware of the cognitive processes mediating their behavior, or that the prime has had an influence on their behavior (for a thorough review of accessibility effects, see Wyer, 2008).

Priming a familiar brand increases the likelihood that the brand enters the consumers' consideration set and is selected as a final choice (Coates, Butler, and Berry, 2006). A single exposure to a previously unfamiliar brand name is sufficient to induce a reliable increase in the selection rate of the primed brand over already familiar brand names. A similar effect has been demonstrated with auditory stimuli. Hearing a brand name once may be enough to increase a brand's familiarity. Increased feelings of familiarity may provoke consumers to misattribute their familiarity of the brand to

an assumption that the brand is popular and well known. If the exposure context is unable to be retrieved, the brand name tends to be considered an existing established brand (Holden and Vanhule, 1999). Even asking consumers about their general purchase intentions (e.g., how likely are you to buy a new automobile?) can increase the likelihood that they make a purchase (Morwitz and Fitzsimons, 2004). This "mere-measurement" effect seems to operate, like more traditional priming effects, by increasing the accessibility of relevant attitudes and beliefs about the object in question.

Priming has been shown to directly influence consumer behavior, as well. Participants primed with prestige goals were more likely to choose relatively expensive and prestigious socks with the Nike brand; participants primed with thrift goals were more likely to choose relatively inexpensive and less prestigious socks with the Hanes brand (Chartrand *et al.*, 2008). Primes do not have to be presented supraliminally in order to have an effect on behavior: participants subliminally primed with the Apple computer logos showed higher creativity scores than those exposed to IBM logos, and participants primed with the Disney channel reported more honest responses to social undesirable questions than did those primed with E! (Entertainment network; Fitzsimons, Chartrand, and Fitzsimons, 2008).

Implicit memory. Marketers have primarily focused their attention on retrieval, or explicit memory (Shapiro and Krishnan, 2001). Explicit memory is assessed via respondents' conscious recollection of a prior exposure to some stimulus, and an intentional attempt to access the information acquired previously. A great deal of consumer behavior is driven by explicit memory (e.g., "Remember to buy eggs and milk," and "I liked the pie at that restaurant."), but implicit memory also has an important role in consumer behavior. *Implicit memory* may be defined as the unintentional, unconscious retrieval of previously acquired information. It is frequently observed by increased performance on indirect tasks that do not demand conscious recollection of past experience. An example of an implicit memory test comparing amnesiac and

non-amnesiac respondents was provided at the beginning of this article.

In assessing ADVERTISING EFFECTIVENESS, Lee (2002) argued that there are two distinct types of implicit memory, perceptual and conceptual, and that these distinct types of implicit memory can be tapped by different measures. She created conceptual primes by having respondents read brand names in sentences (i.e., in a context where conceptual features are salient), and perceptual primes by having respondents read brand names in isolation (i.e., perceptual features of the brand name are salient). Further, consumer behavior was differentially impacted by conceptual and perceptual primes; the former increased the likelihood that consumers would select a primed brand from memory, whereas the latter increased the likelihood that consumers would select a primed brand from a physical layout of different brands. This result has important practical implications for advertisers: when customers are expected to retrieve different product alternatives from memory, persuasive messages should provide relevant contexts to motivate elaborative processing of the brand or product. Otherwise, displaying a prominent product image (perceptual cues) might be a better strategy.

Researchers have supported implicit memory measures as alternatives to explicit recall tasks by showing dissociations between explicit and implicit measures. When participants were asked to do dual tasks (i.e., listen to a short story audio program while advertisements were displayed on slides), their inability to keep their attention focused on the advertisements at the moment of exposure caused different memory performance later in the explicit recall tasks. The number of correct recognitions among participants who were asked immediately after the exposure was quite high (significantly greater than chance levels); however, those who received the recognition task after a week failed at explicit memory retrieval. On the contrary, indirect memory measures were unaffected by either the week delay or attentive states. Overall, implicit tasks revealed an increased likelihood of choosing the advertised brands in all conditions (Shapiro and Krishnan, 2001).

Advertising and product placement seem to have independent and distinct effects on implicit and explicit memory. It is not yet clear whether information that is consciously accessible (explicit memory), and consciously inaccessible (implicit memory) can have additive, or interactive, effects on consumer behavior, but future research should illuminate further effects of implicit memory.

Lacking awareness of behavior. Perhaps one has found oneself unpacking groceries at home, feeling surprised at finding an item come out of his/her grocery bag that he/she does not remember selecting from the shelf: a jar of peanut butter or some Ziploc baggies. Certainly most people have, at one time or another, found themselves parking their own car in their own driveway without any conscious recollection of driving the last few miles home. We have an astounding ability to conduct routine behaviors on autopilot. Riding a bicycle is a remarkably complex task involving the coordinated tasks of steering, balancing, pedaling, breathing, and so on – and it is a task that most people can do without even thinking about it. These are examples of behavior without awareness.

People may be unaware of different aspects of their behavior. Often we are unaware of basic physiological processes, such as breathing. At other times, we are unaware of simple nervous habits, such as repetitive foot tapping. We may also be unaware that a behavior is contingent upon some previous event, such as the effect of a prime. Studying behavior that is outside of awareness is difficult because there are so many ways in which behavior may be outside of awareness – there is no generally agreed upon conceptualization of what, exactly, behavior without awareness actually means.

Still, it is interesting to consider how, and the extent to which, consumer behavior operates outside of conscious awareness. This is an undeveloped area that is wide open for future researchers. As a whole, implicit consumer cognition is a relatively new area of research, so there are numerous gaps where researchers may add substantial contributions. It is an exciting and quickly developing area, with new findings appearing in academic journals monthly.

INTRODUCTION

As new global markets emerge, and existing markets become increasingly segmented along ethnic or subcultural lines, the need to market effectively to consumers who have different cultural values has never been more important. Thus, it is no surprise that in the last several years, culture has rapidly emerged as a central focus of research in consumer behavior. This development followed on the heels of extensive social psychological research on culture, which provided a strong theoretical foundation for the consumer-behavior studies that followed.

What is culture? Culture consists of shared knowledge that provides the standards for perceiving, believing, evaluating, feeling, communicating, and acting among those who share a language, a historical period, and a geographic location. As a psychological construct, culture can be studied in multiple ways – across nations, across ethnic groups within nations, across individuals within nations (focusing on cultural orientation), and across situations through the priming of cultural values. The dimensions of individualism versus collectivism, independence versus interdependence, and analysis versus holism have in recent years received significant research attention. This attention has resulted in a great number of studies revealing both antecedents and consequences of the cultural differences between East Asian and North American cultures. As discussed subsequently, regardless of how culture is studied, cultural distinctions have important implications for advertising content, persuasiveness of appeals, consumer motivation, and consumer judgment processes.

Article scope and overview This article reviews major cultural constructs and theoretical implications of cultural differences in consumer information processing, judgments, and choices. Our review is necessarily selective, focusing on findings specific to the consumer domain rather than

providing a general review of cultural differences (for an excellent general review, see Wyer, Chiu, and Hong, 2009). It should also be noted that because of space limitations, this article does not cover some major topics in cross-cultural consumer behaviors such as self-regulation and risk-taking, as well as methodological issues such as response styles and biases (Shavitt, Lee, and Torelli, 2009; Shavitt, Torelli, and Wong, 2009).

In this article, the cultural constructs of individualism/collectivism and the independent/interdependent self-construals associated with them are given special attention because extensive research has demonstrated the implications of these distinctions for processes and outcomes relevant to consumer behavior. The most recent refinements to these constructs are briefly reviewed in an attempt to identify additional cultural variables likely to enhance the understanding of cross-cultural consumer behavior. We also review cultural differences in thinking styles as a major emerging cultural distinction and focus on their implications for consumer-behavior research. Finally, we close with a review of cross-cultural differences in advertising content and the persuasiveness of appeals.

KEY CONSTRUCTS AND DIMENSIONS OF CULTURE

Individualism versus collectivism. The constructs of *individualism* and *collectivism* represent the most broadly used dimensions of cultural variability for cross-cultural comparison. In individualistic cultures, people value independence from others and subordinate the goals of their in-groups to their own personal goals. In collectivistic cultures, in contrast, individuals value interdependent relationships to others and subordinate their personal goals to those of their in-groups (Hofstede, 1980; Triandis, 1995). The key distinction involves the extent to which one defines the self in relation to others. In individualistic cultural contexts, people tend to have an independent self-construal whereby the self is defined as autonomous and unique. In collectivistic cultural contexts, by contrast, people tend to have an interdependent self-construal whereby

the self is seen as inextricably and fundamentally embedded within a larger social network of roles and relationships (Markus and Kitayama, 1991).

National cultures that celebrate the values of independence, such as the United States, Canada, Germany, and Denmark, are typically categorized as individualistic societies in which an independent self-construal is common. In contrast, cultures that nurture the values of fulfilling one's obligations over one's own personal wishes, including most East Asian and Latin American countries, are categorized as collectivistic societies in which an interdependent self-construal is common (Hofstede, 1980; Triandis, 1995).

A large body of research in psychology has demonstrated the many implications of individualism/collectivism and independent/interdependent self-construals for social perception and social behavior (Markus and Kitayama, 1991; Triandis, 1995). These findings indicate consistently that individualists and people with an independent self-construal are oriented toward products and experiences that promote achievement and autonomy, offer personal benefits, and enable expression of one's distinctive qualities. On the other hand, collectivists and people with an interdependent self-construal are oriented toward products and experiences that allow one to avoid negative outcomes, maintain harmony and strong social connections with others, and dutifully fulfill social roles.

Although a given self-construal can be more chronically accessible in a particular culture, cultures generally provide sufficient experiences with independent and interdependent views of the self to allow either type of self-construal to be primed (Oyserman, Coon, and Kimmelmeier, 2002; Oyserman and Lee, 2007). Numerous studies have established that these activated self-views impact judgments in ways that parallel cross-national differences (Shavitt, Lee, and Torelli, 2009), for instance, by activating distinct self goals (Lalwani and Shavitt, 2009). People in general, and especially bicultural people, can readily switch back and forth between independent and interdependent cultural frames in response to their contexts. For instance, Lau-Gesk (2003) found that independent (interdependent) self-construals were temporarily activated when bicultural

consumers were exposed to individually focused (interpersonally focused) appeals.

In sum, the distinctions between individualistic and collectivistic societies, and independent and interdependent self-construals, are crucial to the understanding of cross-cultural differences in consumer behavior. The studies to be reviewed here offer extensive evidence that these cultural classifications have fundamental implications for consumption-related outcomes.

Refined individualism versus collectivism. The conceptualizations of individualism and collectivism, and independence/interdependence, have historically been broad and multidimensional, summarizing a host of differences in focus of attention, self-definitions, motivations, emotional connections to in-groups, as well as belief systems and behavioral patterns (Hofstede, 1980; Oyserman, Coon, and Kimmelmeier, 2002). In addition, recent studies have proposed useful refinements to these broader cultural categories (Shavitt, Lee, and Torelli, 2009). These studies suggest that the nature and meaning of individualism and collectivism varies across gender and ethnic lines, as well as across family groupings and institutions. Although the breadth of the individualism-collectivism constructs lends integrative strengths, research indicates that further refinements of these categories can enhance the prediction of consumer behavior.

The horizontal/vertical distinction. With in the individualism-collectivism framework, Triandis *et al.* (Triandis, 1995; Triandis and Gelfand, 1998) have recently introduced a further distinction between societies that are *horizontal* (valuing equality) and those that are *vertical* (emphasizing hierarchy), and a scale to measure these orientations at the individual level. The horizontal/vertical distinction emerges from the observation that American or British individualism differs from, say, Norwegian or Danish individualism in much the same way that Japanese or Korean collectivism differs from the collectivism of the Israeli kibbutz. Specifically, in vertical individualist (VI) societies (e.g., United States and Great Britain), people strive to become distinguished and acquire status via competition (Shavitt, Torelli and Wong,

2009); whereas in horizontal individualist (HI) cultural contexts (e.g., Sweden and Norway), people value uniqueness but are not especially interested in becoming distinguished and achieving high status (Nelson and Shavitt, 2002). In contrast, in vertical collectivistic (VC) societies (e.g., Korea and Japan), people emphasize the subordination of their goals to those of their in-groups, submit to the will of authority, and support competitions between their in-groups and out-groups. Finally, in horizontal collectivist (HC) cultural contexts (e.g., exemplified historically by the Israeli Kibbutz), people see themselves as similar to others, and emphasize shared goals and sociability, but instead of submitting to authority, their view of power focuses on benevolence and helping others (Shavitt, Lee, and Torelli, 2009).

However, the modal comparisons in consumer research are between the United States (VI) and any of a number of Pacific Rim countries (VC). This means that much of what is known about consumer behavior in individualistic and collectivistic societies reflects vertical forms of these syndromes and may not generalize, for example, comparisons between Sweden (HI) and Israel (HC) or other sets of horizontal cultures. As an example, conformity in product choice, as examined by Kim and Markus (1999), may be a tendency specific to VC cultures, in which deference to authority and to in-group wishes is stressed. Much lower levels of conformity may be observed in HC cultures, which emphasize sociability but not deference (Triandis and Gelfand, 1998). Thus, differences in consumers' conformity between Korea (VC) and the United States (VI) may not characterize broad individualism-collectivism differences, because levels of product conformity in HC contexts might not exceed those in HI contexts.

Indeed, several recent studies of this horizontal/vertical cultural distinction have provided evidence for its value as a predictor of new consumer psychology phenomena and as a basis for refining the understanding of known phenomena (Shavitt *et al.*, 2006). For instance, Lalwani, Shavitt, and Johnson (2006) showed that differences in the self-presentational responses observed for individualists and collectivists are mediated at the individual level

by the horizontal but not the vertical versions of these cultural orientations. This suggests that culturally linked self-presentational efforts reflect distinct goals of being seen as self-reliant and capable (valued in HI contexts) versus sociable and benevolent (valued in HC contexts).

Further evidence for the value of the horizontal-vertical distinction comes from a study of country-of-origin effects. Gürhan-Canli and Maheswaran (2000) demonstrated that the tendency to favor products from one's own country over foreign products emerged more strongly in Japan (a VC culture) than in the United States (a VI culture). Mediation analyses using individual consumers' self-rated cultural values further indicated that only the vertical aspect of individualism and collectivism accounted for the country-of-origin effects in Japan. In other words, the collectivistic tendency to favor one's own country's products appeared to be driven by cultural values that stress hierarchy, competition, and deference to in-group wishes, not by values that stress interdependence more generally.

In line with this, as noted earlier, research suggests that mental representations of power in terms of status and competition versus benevolence differ reliably between vertical and horizontal cultural backgrounds and orientations. These differences impact consumer information processing and the interpretation of power-related stimuli (Shavitt, Lee, and Torelli, 2009). Finally, content analyses of magazine advertisements in several countries suggested that status-oriented themes of hierarchy, luxury, prestige, and distinction were generally more prevalent in societies presumed to have vertical cultural profiles (e.g., Korea, Russia) than a horizontal cultural profile (Denmark) (Shavitt *et al.*, 2006).

Culture and thinking styles. East Asian and North American cultural differences have been well documented in social psychological research, especially in terms of the differences in individualistic-collectivistic values and independent-interdependent self-systems (Markus and Kitayama, 1991). Many of these cross-cultural studies of consumer behavior have provided evidence that advertising (such

as magazine ads, Internet advertising, and TV commercials) from Western cultures is in general more individualistic and less collectivistic than advertising from Asian cultures (Morling and Lamoreaux, 2008), and that consumers from Western cultures are more likely to be persuaded by individualistic ads and those from East Asian cultures are more likely to be persuaded by collectivistic ads (Han and Shavitt, 1994). However, relatively little research has been done on cross-cultural differences in consumers' thinking orientations. The following section provides a general review of cultural differences in thinking styles in addition to the findings of relevant studies of consumer behavior and advertising effects.

Analytic versus holistic thinking. Broadly speaking, Westerners tend to adopt an analytic thinking style that emphasizes the independence of individual objects, whereas East Asians tend to adopt a holistic view emphasizing that the world is composed of interrelated elements (Nisbett *et al.*, 2001). The analytic style of Westerners and the holistic style of East Asians have been demonstrated in various cognitive domains such as attention, causal reasoning, perception of change, tolerance of contradiction, and categorization.

The analytic style of attention is field independent (mainly oriented toward an object itself), whereas holistic attention is field dependent (focused on the relationship between objects and/or the field in which they are embedded) (Nisbett *et al.*, 2001). This difference in the orientation of attention is also seen in the way East Asians and Westerners perceive and explain social events. East Asians tend to assume that each element in the world is somehow intertwined, and thus an event or object can be understood only in the context of the whole set of relevant factors. By contrast, Westerners tend to explain a certain event in terms of direct causal links, thereby considering fewer reasons than East Asians, who tend to consider a broader set of reasons, regardless of their relevance to the event (Choi *et al.*, 2003).

Furthermore, in explaining causality of a social event, analytic thinkers tend to focus on the internal dispositions of an actor, whereas holistic thinkers tend to consider a broader set of

reasons (including both dispositional and contextual information) and are therefore less likely to attribute an outcome to an actor's internal characteristics (Nisbett *et al.*, 2001). This has implications for brand judgments, as well. Monga and John (2007) found that negative publicity influences analytic (vs. holistic) thinkers more heavily, and thus changes their beliefs about a brand to a greater degree because analytic thinkers are less likely to consider contextual information, and thus are more likely to attribute negative product information to the brand.

From the analytic perspective, objects exist independently, and thus the essence of the objects is stable over time. This assumption promotes a linear perception of change in which no drastic deviation is expected in the pattern of stability or change of a phenomenon (Nisbett, 2003). By contrast, the holistic view of the world assumes that objects are interrelated, and therefore it is less likely that a phenomenon will remain stable over time. This perspective results in a cyclic perception in which people tend to predict fluctuating trends for an event. For example, in predicting future stock-market trends and making investment decisions, Canadians are more likely to make judgments based on recent trends than are Chinese people; thus, when compared to the Chinese, Canadians are more willing to buy stocks when they are in an increasing trend and less willing to buy when stock prices are decreasing (Ji, Zhang, and Guo, 2008).

The cyclic perception of change and expectation of instability prevalent among East Asians renders a Yin-Yang belief that a characteristic of an object can potentially transform into its opposite. Consequently, East Asians tend to hold a dialectical perception in which apparently opposing concepts can simultaneously be true and can peacefully coexist (Nisbett *et al.*, 2001). When confronted with opposing propositions, East Asians tend to resolve contradictions by choosing a middle ground, whereas Westerners tend to rely on formal logic in resolving contradictions by choosing one of the opposing propositions. For example, US consumers tend to resolve incongruities with an attenuation strategy in which one piece of information is favored over another inconsistent piece of information. In contrast, Hong Kong Chinese consumers tend

to follow an additive strategy in which both pieces of information are combined to influence judgments (Aaker and Sengupta, 2000).

East Asians and Westerners also perceive conflicting emotions in different ways. For example, Bagozzi, Wong, and Yi (1999) showed that Chinese tend to hold a dialectical perception that pleasant and unpleasant emotions can be experienced at the same time. Thus, their frequency judgment for pleasant emotions is positively correlated with their frequency judgment for unpleasant emotions. By contrast, this study found that for Americans the perceived frequency of pleasant emotions is inversely correlated with the perceived frequency of unpleasant emotions. Schimmack, Oishi, and Diener (2002) analyzed 38 nationalities and demonstrated that this cultural difference results from dialectical thinking, not from a difference in individualistic-collectivistic values. Moreover, Williams and Aaker (2002) demonstrated that opposing emotions (e.g., both happiness and sadness) in persuasion appeals elicit more positive attitudes among Asian Americans than among European Americans.

Westerners pay more attention to individual objects and attribute causality to them, whereas East Asians focus more on the field. Westerners are more accustomed to formulating rules that govern internal properties of objects and tend to categorize things by applying those rules. In contrast, East Asians organize objects on the basis of their relationship to other objects or to the field (Nisbett, 2003), and therefore they tend to categorize objects according to their overall similarities. Thus, when presented with pictures of a panda, a monkey, and a banana, East Asians tend to categorize the monkey and banana together based on the relationship between the two, whereas Westerners tend to categorize the panda and monkey into one group based on the traits that characterize them (Ji, Zhang, and Nisbett, 2004).

Cultural differences in the way people categorize objects (rule/trait-based vs. similarity/relationship-based) also appear in the way they organize and store brand information. For example, Ng and Houston (2006) showed that Americans are less likely to retrieve brand exemplars (i.e., specific products or subcategories) than brand beliefs (i.e., general

descriptive or evaluative thoughts), whereas the reverse was the case for Singaporeans. These results emerged from an analytic tendency to focus on "global beliefs" abstracted from prior product experiences and a holistic tendency to focus on contextual and incidental details about the product. Similarly, Monga and John (2008) found that, compared to Americans, Indians tend to perceive a higher degree of fit between a parent brand (e.g., Kodak) and its brand extension (e.g., Kodak filing cabinet, Kodak greeting cards), and to evaluate the brand extension more positively. This result reflects Indians' holistic tendency to base their judgments more heavily on the relationships between brand extensions and parent brands than do their American counterparts.

A variety of methods and techniques have been developed to measure cultural differences in thinking styles (Choi, Koo, and Choi, 2007; Ji, Zhang, and Nisbett, 2004; Monga and John, 2007), including responses to cognitive tasks, scenarios and questions, physiological measures, a scale, and analyses of various cultural products. Furthermore, priming an independent versus interdependent view of self has also been found to promote analytic and holistic modes of thinking, respectively. For example, people primed with an independent self-view were more likely to focus on a focal object and thus were better at finding an embedded figure by separating the figure from its background than were those primed with an interdependent self-view (see Oyserman and Lee, 2007, for a review).

Additional dimensions. Numerous other cultural distinctions deserve further attention in consumer research. A focus upon these relatively under-researched constructs as antecedents may allow for broadening the range of cultural differences beyond those currently investigated. For instance, Schwartz's (1992) circumplex structure of values, which is highly robust cross-nationally, parallels the HI, VI, HC, VC typology and offers a particularly detailed and comprehensive basis for classification. In his large-scale studies of work values, Hofstede (1980) derived three other dimensions of cultural variation in addition to individualism: *power distance* (acceptance of power inequality in

organizations, a construct conceptually relevant to the vertical/horizontal distinction), *uncertainty avoidance* (the degree of tolerance for ambiguity or uncertainty about the future), and *masculinity/femininity* (preference for achievement and assertiveness versus modesty and nurturing relationships). Indeed, individualism was the second dimension identified by Hofstede (1980), whereas power distance emerged as the first dimension. A few marketing-oriented studies have employed Hofstede's nation-level classifications (Shavitt, Lee, and Torelli, 2009), but more potential remains for identifying consequences for consumer judgments and behaviors. For instance, uncertainty avoidance has been conceptualized as a syndrome related to anxiety, rule orientation, need for security, and deference to experts (Hofstede, 1980). As such, one might speculate that the level of uncertainty avoidance in a culture will predict the tendency for advertisements to use fear appeals or appeals to safety and security, and the tendency for advertisements to employ expert spokespersons. Differences along this cultural dimension may also predict patterns in the diffusion of product innovations, particularly innovations whose purchase entails a degree of risk.

CULTURE AND PERSUASIVE APPEALS

Most research on cultural influences on judgment and persuasion has examined the implications of individualism/collectivism or independent/interdependent self-construals. In general, the findings suggest that the prevalence or the persuasiveness of a given type of appeal matches the cultural value orientation of the society (Shavitt, Lee, and Torelli, 2009). For instance, appeals to individuality, personal benefits, and achievement are usually more prevalent and persuasive in individualistic compared to collectivistic cultures, whereas appeals to group benefits, harmony, and conformity are usually more prevalent and persuasive in collectivistic compared to individualistic cultures. Such evidence for "cultural matching" in the nature of appeals has been followed by studies examining the distinct psychological processes driving persuasion across cultures. These studies suggest that culture can affect how people process and interpret product-related

information. It can determine the type of information that is weighed more heavily for making judgments (e.g., product attributes vs other consumers' opinions). However, brand and product characteristics can constrain the role of cultural variables in information processing and persuasion, with some brands and products serving as stronger carriers of cultural values (Shavitt, Torelli and Wong, 2009).

Cultural differences in the content of message appeals. Cross-cultural content analyses of advertisements can yield valuable evidence about distinctions in cultural values. For instance, American advertisers and consumer researchers often assume that consumer learning about the brand precedes other marketing effects, such as liking and buying the brand. Thus, advertisements that attempt to teach the consumer about the brand are typical in the United States, although other types of advertisements are also used.

In contrast, as Miracle (1987) suggested, the typical goal of advertisements in Japan appears very different. There, advertisements tend to focus on "making friends" with the audience and showing that the company understands their feelings. The assumption is that consumers will buy once they feel familiar with and have a sense of trust in the company. Because Japan, Korea, and other Pacific Rim countries are collectivist cultures that tend toward implicit and indirect communication practices (Triandis, 1995), Miracle suggested that the mood and tone of commercials in these countries will be particularly important in establishing good feelings about the advertiser. Several studies have supported these notions, showing that advertisements in Japan and Korea, compared to those in the United States, rely more on symbolism, mood, and aesthetics and less on direct approaches such as brand comparisons (Shavitt, Lee, and Torelli, 2009). The ads may be equally informative about the brand across cultures. It is the type of appeal that will vary.

For instance, a content analysis of magazine advertisements revealed that in Korea, compared to the United States, advertisements are more focused on family well-being, interdependence, group goals, and harmony, whereas they are

less focused on self-improvement, ambition, personal goals, independence, and individuality (Han and Shavitt, 1994). However, as one might expect, the nature of the advertised product moderated these effects. Cultural differences emerged strongly only for products that tend to be purchased and used along with other persons (e.g., groceries, cars). Products that do not tend to be shared (e.g., health and beauty aids, clothing) are promoted more in terms of personal, individualistic benefits in both countries.

Paralleling the overall cross-national differences, a content analysis by Kim and Markus (1999) indicated that Korean advertisements, compared to US advertisements, were characterized by more conformity themes (e.g., respect for collective values and beliefs) and fewer uniqueness themes (e.g., rebelling against collective values and beliefs). Website content in Eastern and Western countries also appears to differ in the emphasis on individual versus collective activities (Shavitt, Lee, and Torelli, 2009).

Finally, it is important to note that, in countries experiencing rapid economic growth, advertising content does not necessarily reflect existing cultural values, instead promoting new, aspirational values such as individuality and modernity. For instance, in China, in recent years, westernized ad appeals are increasingly common. Appeals to youth/modernity, individuality/independence, and technology are especially salient in Chinese advertisements that target the younger generation (Zhang and Shavitt, 2003). Similarly, during a period of rapid transition in South Korea's economy (1968–1998), content analysis of advertisements revealed substantial shifts toward individualistic, modernity-oriented appeals (Han and Shavitt, 2005).

Cultural differences in judgment and persuasion.

Research suggests that the persuasiveness of appeals may mirror the cultural differences in their prevalence. An experiment by Han and Shavitt (1994) showed that appeals to individualistic values (e.g., “Solo cleans with a softness that you will love”) were more persuasive in the United States and appeals to collectivistic values (e.g., “Solo cleans with a softness that your family will love”) were more persuasive in Korea.

Again, however, this effect was much more evident for products that are shared (laundry detergent, clothes iron) than for those that are not (chewing gum, running shoes).

Zhang and Gelb (1996) found a similar pattern in the persuasiveness of individualistic versus collectivistic appeals in an experiment conducted in the United States and China. Moreover, this effect appeared to be moderated by whether the advertised product is socially visible (camera) versus privately used (toothbrush). Finally, Wang and Mowen (1997) showed in a US sample that individual differences in separateness/connectedness self-schema (i.e., the degree to which one views the self as independent of or interconnected with important others) predicts attitudes toward individualistic versus collectivistic ad appeals for a credit card. Thus, cultural orientation and national culture have implications for the effectiveness of appeals. However, such cultural differences would only be anticipated for those products or uses that are relevant to both personal and group goals.

Cultural differences in persuasion are also revealed in the diagnosticity of certain types of information. For instance, Aaker and Maheswaran (1997) showed that consensus information regarding other consumers' opinions is not treated as a heuristic cue by Hong Kong Chinese (as it is in the United States) but is instead perceived and processed as diagnostic information. Thus, collectivists resolve incongruity in favor of consensus information, not brand attributes. This would be expected in a culture that stresses conformity and responsiveness to others' views. On the other hand, cues whose (low) diagnosticity is not expected to vary cross-culturally (e.g., number of attributes presented) elicit similar heuristic processing in the United States and Hong Kong.

Finally, because cognitive associations with power vary with horizontal and vertical cultural orientations and with ethnicity, as noted earlier, Torelli *et al.*, found differences in the interpretive processes and mindsets triggered when power is salient. Specifically, people whose cultural orientation predisposes a status-oriented view of power activate cognitive processes that facilitate defending their power, such as reasserting control by confirming

prior stereotypes about a brand. In contrast, people whose cultural orientation predisposes a benevolence-oriented view of power activate cognitive processes that facilitate helping others, such as by forming accurate, careful impressions of brands (Shavitt, Torelli and Wong, 2009).

CONCLUSIONS

As marketing efforts are increasingly globalized, understanding cross-cultural consumer behavior has become a key focus of consumer research. In recent years, research in consumer behavior has addressed a broadening set of cross-cultural issues and dimensions. Research has provided an enhanced understanding of the relations between culture and self-construal, motivation, thinking style, and consumer persuasion. Research has also begun to address the psychological mechanisms underlying cross-cultural differences in consumer judgments, and the products and contexts for which these differences are most likely to be observed. Understanding cultural differences has become crucial for effective marketing and advertising. In future research, it will be important to further distinguish cultural similarities and differences in consumer judgments, identify within-culture or subgroup differences that parallel between-culture differences, and explore their rich implications in consumer behavior.

consumer decision making

Haiyang Yang and Ziv Carmon

INTRODUCTION

The standard benchmark for models of consumer decision making against which all other models are typically compared is that of *homo economicus* (economic man). This elegant model suggests that consumers are rational actors who evaluate all relevant choice alternatives, assess the utility (value) that each can provide, and choose the one that they expect to provide the most utility. Different versions of this prescriptive model vary in their assumptions and in their descriptive fidelity (the extent to which they accurately describe how consumers actually think and behave), but on the whole, that view of consumer decision making is overly simple. For example, it assumes that consumers are sophisticated thinkers who process information effectively, efficiently, and without bias, and know their preferences.

Decades of descriptive research about consumer judgment and decision making shows that consumers systematically deviate from this model in important ways. Consumers' capacity to process information is limited, yet they commonly face a great deal of information and must therefore trade-off the accuracy of their decisions and the mental effort involved. Rather than choosing the optimal option (the one that they expect will maximize utility), many tend to select an option that is "good enough". Moreover, consumers often do *not* know their preferences. They construct rather than reveal their preferences when those are elicited, and these constructed preferences are sensitive to the decision context and the manner in which these preferences are elicited (Bettman, Luce, and Payne, 1998). In addition, consumers are influenced by meta-goals such as a desire to manage negative emotions like potential regret or conflict, or the extent to which their choice seems easy to justify. Complicating the picture further, rather than simply maximizing pleasure and minimizing pain, consumers sometimes pursue higher order goals such as bolstering their self-esteem, achieving a sense of mastery, or seeking deeper meaning.

In this chapter, we review some of the current knowledge on consumer decision making, highlighting a few ways in which consumers deviate from *homo economicus*. The review is *very* selective as we were restricted in how much we could write and cite, allowing us to cover and to acknowledge few of the papers that contributed to the body of knowledge that we describe. In the following sections we first discuss the impact of decision task and context on consumer preference, and then look at how the interplay of affect and cognition shapes consumer decision making. We also review factors influencing consumers' forecasts of future consumption experiences and discuss the relationship between utility maximization behavior and consumer well-being.

DECISION TASK AND CONTEXT

Decisions are easy when consumers know what they want. Unfortunately that is frequently not the case; there are many instances in which consumers have but a sense of what they prefer, and must construct their preferences "on the fly" when a judgment or a choice is called for. Because consumers are affected by a variety of perceptual and judgmental biases, and since they are also often unable or unwilling to invest much time, effort, or attention in constructing their preferences, these preferences can be sensitive to how they were elicited. Examples of significant preference elicitation characteristics discussed below include choice set size, attribute quantity, option similarity and justifiability, presentation format, and response mode.

Choice set size and attribute quantity. Consumers who face a complex judgment or decision frequently use heuristics, decision strategies that simplify the task and are hoped to lead to a decision that is close to the best possible one (see Bettman, Luce, and Payne, 1998). Some heuristics avoid trading off attributes against one another. Such strategies are named *noncompensatory*, as an advantage in one attribute cannot compensate for a disadvantage in others. A lexicographic strategy is a notable example: consumers select the option with the highest value on the attribute that they consider most important, ignoring information about other attributes (in case of ties, they also consider

2 consumer decision making

the second most important attribute, etc.). Elimination by aspects is another noncompensatory strategy: consumers screen the choice options, and at each round of screening they select the most important attribute and eliminate options that do not exceed a minimum level on that attribute; this process continues until a single option remains. Compensatory strategies, on the other hand, do trade-off among attributes: a high value on one attribute can thus compensate for a low value on another. An example of a compensatory strategy is weighted adding: consumers evaluate each attribute of an option and compute a weighted total score for the option; after obtaining the scores for all the options in the set, consumers can then identify the option with the highest rating. Note that the examples we describe are “pure” strategies, whereas in reality, consumers may use a mixture of strategies or simplified variants of the strategies for a given decision.

Consumers tend to believe that to reach a good decision it is desirable to examine many alternatives, and seek as much information as they can reasonably find about these choice alternatives. However, information about many attributes or choice sets consisting of many options can make decisions too difficult. To illustrate, Iyengar and Lepper (2000) found that more consumers were drawn to a sampling booth of gourmet jams when it displayed 24 different types of jams, compared to when only 6 types were displayed. However, when only 6 jams were displayed more purchases were made – 10 times more than when 24 jams were displayed. These researchers also found that consumers were more satisfied with their choices when they chose from smaller sets of options. In conclusion, it appears that although people often want more options and more information, these are not necessarily beneficial.

Option similarity and justifiability. Consumer decisions are influenced by the extent to which choice options seem similar to one another. For instance, consider consumers choosing between two shirts: *A* that is comfortable to wear but not very stylish, and *B* that is stylish but not so comfortable. Adding to the choice set another shirt, *C*, that is slightly less comfortable and stylish than *A*, but more comfortable than *B*, can increase the attractiveness and relative choice

share of shirt *A*. This phenomenon, known as the *asymmetric dominance effect* (attraction effect), violates the economic principle of regularity: adding an alternative to a choice set should not increase the choice share of any option in the original set (Huber, Payne, and Puto, 1982). This effect occurs because presence of the dominated option (shirt *C*) increases the appeal of the dominating option (shirt *A* in our example) as contrast between the former and the latter options helps the trade-off between the different dimensions (style and comfort) appear more favorable to the dominating option (shirt *A*) versus the alternative (shirt *B*).

Consumers are influenced by the extent to which they feel that they can easily justify their decisions, a notion named *reason-based choice*. This notion predicts a variety of interesting phenomena, such as a preference for so-called compromise options (Simonson, 1989). To illustrate, consider our shirt example; if we add to the original choice set of shirts *A* and *B* a shirt *D* that is more comfortable but less stylish than *A* and *B*, both the attractiveness and choice probability of shirt *A* are likely to increase. This is because consumers tend to find choosing an intermediate option (shirt *A*) easier to justify than extreme options (shirt *B* and *D*). This phenomenon is known as the *compromise effect* or *extremeness aversion*.

Presentation format. Consumer decision making is often influenced by how information is organized and presented, as consumers tend to focus on the information that is explicitly displayed and use it in the form that it is displayed. For example, consumers can use price information better when product and price information is presented in a list sorted by unit price than when the same information is displayed in a traditional store setting, price tags on product shelves (Russo, 1977). That said, consumers do sometimes restructure information to make it more suitable for decision making when it seems too arduous to follow the given format.

Information can be displayed so as to establish different standards of comparison (referred to as *reference points*), which, in turn, influence consumer decision making. For example, if consumers are offered a full-featured product

and asked to delete features that they do not want, they tend to choose significantly more features than if they are given a base model and asked to add the features they desire (Park, Jun, and MacInnis, 2000). This tendency has been attributed to two important notions in consumer decision making: reference dependence and loss aversion. According to reference dependence, consumers evaluate options by comparing them to reference points rather than evaluating them in absolute terms. In our example, the configuration that consumers first see serves as the reference point against which subsequent configurations are compared. The notion of loss aversion suggests that giving up an item, a feature, or a level of a feature, hurts more than acquiring the same thing feels good; in other words, losing something looms larger than gaining the same thing (Kahneman and Tversky, 1979). In our example, loss aversion drives consumers to add more features than they detract.

Loss aversion can also lead to a preference for the status quo. For instance, in countries where organ donation is the default decision (status quo) and people are given the option to opt out, consent rates tend to be very high, while in countries that generally seem comparable where the default decision is not to donate (an alternative status quo) and people can choose to opt in, consent rates are much lower (3–20 times lower according to Johnson and Goldstein, 2003).

Even arbitrary reference points can impact decision making. For example, Tversky and Kahneman (1974) used a roulette wheel to randomly generate a number, then asked participants in their experiment whether the number of African countries in the UN was higher or lower than that number, and then asked the participants to estimate the actual number of African UN member countries. Those who first saw a large (roulette derived) number estimated the number of African countries in the UN as significantly greater than those who saw a small (roulette derived) number.

More recent research showed that arbitrary anchors can also influence assessments of a sequence of items. The subsequent valuations tend to be “coherent” with respect to perceived differences among the products, “the entire pattern of valuations can easily create an illusion of order, as if it is being generated by stable

underlying preferences” (Ariely, Loewenstein, and Prelec, 2003, p. 73). For example, the willingness to pay for a single bottle of wine was shown to be heavily influenced by an arbitrary number, but bids for multiple units of the same wine followed a reasonable logic: if willingness to pay for one bottle was \$X, the willingness to pay for two bottles was a bit less than 200% of \$X, for three bottles it was a bit less than 150% of the bid for two bottles, and so on. This phenomenon was named *coherent arbitrariness*, as the first bid is arbitrary but subsequent bids follow a coherent pattern.

Consumers’ judgment of an option can also be shaped by whether the option is presented and evaluated separately or jointly with other options; if a choice option is rated favorably in singular evaluation, consumers may prefer the option less if the option is evaluated jointly with other options; conversely, if the option is not rated very positively in singular presentation and evaluation, its rating may improve in joint judgment (Hsee and Leclerc, 1998).

Meta-cognitive experiences related to presentation format can also influence choice. As an example, when choice information is presented in a fuzzy, difficult-to-read font, the resulting perceptual difficulty (of reading) can be attributed to the choice set. Consumers may infer that choosing between the options is difficult, and this can increase the likelihood of choosing to put off a decision (choice deferral) (Novemsky *et al.*, 2007).

Response mode. Procedure invariance, another important principle in the classical economic decision-making paradigm, requires that equivalent preference elicitation procedures elicit the same preferences. A well-known violation of procedure invariance is the prominence effect (Tversky, Sattath, and Slovic, 1988): prominent (important) attributes are weighed more heavily when people choose among options than when they evaluate the same options in other ways, such as matching. Price matching, for example, asks for the price level at which the options will be equally attractive. To illustrate, when choosing between two programs to reduce traffic accident fatalities, one saving more lives but costing more than the other, people weigh saved lives (the more prominent attribute) more

4 consumer decision making

heavily than cost. They therefore tend to choose expensive programs saving more lives, reflecting high willingness to pay to save a life. But when asked a price matching question, such as at what price the program saving more lives is equivalent to the inexpensive program saving fewer lives (the price beyond which the less expensive program saving fewer lives is preferred), they indicate a price roughly proportional in cost per life saved, reflecting lower willingness to pay to save a life.

As another example, consumers' value assessment of the same item can vary greatly depending on how it is assessed. For instance, the highest sum consumers will pay to obtain an item is typically very different from the lowest sum for which they will part from the item. This is true even if potential differences between buyers and sellers (such as liquidity constraints and information asymmetries) are controlled for, and although both types of value assessments should reflect the value that the consumer associates with owning the item. This robust phenomenon (see Maddux et al., in press, for discussion on variation across cultures), named the *endowment effect* (Kahneman, Knetsch, and Thaler, 1990), is due to a combination of factors. One is loss aversion. Another is that buyers and sellers use different heuristics to assess value, each focusing on and thus assessing different aspects of the potential transaction. Buyers focus on the money they stand to forgo should the transaction take place, and thus consider such things as opportunity costs (e.g., other things they could purchase with the money). Sellers, on the other hand, focus on the item that they would forgo should the transaction take place (Carmon and Ariely, 2000).

As yet another example, hedonic dimensions are weighed less heavily in acquisition decisions (which of several options to obtain) than in forfeiture decisions (which of several options to forgo). To illustrate, consumers wishing to buy a chocolate bar and an equally priced notepad, but who can only afford one, are more likely to buy the chocolate when choosing which option to forgo (e.g., if they have both items in their shopping cart when they notice the budget constraint) than when choosing which to select (e.g., if they have neither item in the cart when

they notice the budget constraint; Dhar and Wertenbroch, 2000).

AFFECT IN DECISION MAKING

Affect can have considerable impact on consumer decision making. Choices can be so affect-laden that trade-offs among them evoke strong unpleasant emotions. Some consumer decisions reflect reluctance to experience such emotions. For example, consumers sometimes choose to maintain a status quo so as to avoid the unsettling emotions involved with agonizing over which option they should choose instead (Luce, 1998).

Affective state. Affect can significantly influence decision-making processes. Positive affect can sometimes lead to more efficient decision making, for example. Also, when in a positive mood, consumers can decide more quickly and search less for redundant information. When experiencing negative emotions, on the other hand, consumers may seek to make accurate choices to improve how they feel, and may thus engage in more systematic, effortful information processing (Isen, 2001).

How consumers feel as they decide can also color their evaluations. For example, when assessing an object, consumers partly infer their assessment from how the product experience "seems to feel." This is referred to as the "how-do-I-feel-about-it heuristic," or "affect-as-information" (Pham, 1998; Schwarz and Clore, 1988). Incidental emotions (having little to do with the evaluated product, such as gloominess on a cloudy day), can affect how consumers feel at that point in time and can thus contaminate their product assessments, as consumers partly infer their evaluations from how they feel when they assess the product. Thus, positive incidental emotions can lead to more favorable assessments and the opposite is true of negative incidental emotions. Such effects of incidental emotions can be reduced if their true source is made salient. For example, negative effects of gloominess during a cloudy day on product assessment can be reduced if consumers are first explicitly asked what the weather is like then.

Anticipated regret. Anticipated emotions can also influence consumer decision making. For example, when consumers try to predict how they would feel if they were to have made a poor decision, they are more likely to purchase a product that is currently on sale rather than wait for a better sale; they are also more likely to choose higher priced well-known brands (Simonson, 1992). Bar-Hillel and Neter 1996 describe another interesting example of the impact of anticipated affect: participants were first given a lottery ticket and then asked if they would exchange the ticket for another that had objectively better odds. Surprisingly, most participants did not want to trade due to the regret they expected to feel if their original ticket won. More generally, consumers' concerns about the regret that they might feel should their choice turn out badly drive them to seek "safe" choices (*see* EMOTION).

SELF-CONTROL

Consumers regularly face choice situations involving indulgent and utilitarian options. They often choose the short lived satisfaction that comes from indulging themselves at the expense of their longer term goals and interests, even when the negative consequences of their decisions are clear. Owing to the so-called "hot-cold empathy gap," consumers often fail to predict such transgressions when they are in a "cold state" – removed from the tempting situation, in physical distance, in time, or in their thoughts. Being in such a cold state, it is easy to mispredict one's ability to act virtuously in the face of temptation. Worse yet, lapses are often exacerbated by visceral states such as feeling significant deprivation, hunger, or lust (Loewenstein, 1996). For example, consumers who shop for food while they are hungry, tend to buy more than they would otherwise purchase, or will want to consume.

Wertenbroch (1998) distinguishes between vice and virtue goods. Vices (such as rich chocolate cake, or cigarettes) are typically preferred to virtues (such as fresh broccoli, or fat free versions of fatty foods) when consumers focus on the immediate consequences of consumption. To solve their self-control problems, consumers sometimes proactively ration their decisions. For

example, they sometimes ration purchase quantity, limiting their stock of vice goods and thus consumption opportunities. Consumers of vice goods seeking to regulate their behavior may thus agree to pay higher unit price (for instance, avoid buying cigarette cartons despite the expected savings). Interestingly, some consumers become so future-oriented that they find it difficult to indulge (Kivetz and Simonson, 2002); to cope with this difficulty, they sometimes precommit to indulge (for example, choose luxury items rather than cash of equal or greater value, as a reward from a loyalty program).

Consumer decision making is shaped by spontaneous affect as well as by cognitive processes. When consumers' cognitive resources are constrained, they are more likely to choose options with higher immediate affective rewards (e.g., chocolate cake); conversely, when processing resources are less constrained, consumers are more likely to choose options with more favorable cognitions (e.g., fruit salad; Shiv and Fedorikhin, 1999). If options are presented vividly (e.g., real chocolate cake and fruit salad are physically placed in front of the consumer), even consumers with sufficient cognitive resources to elaborate on their decisions are likely to be swayed by affective considerations and choose to indulge (*see* IMPULSIVE AND COMPULSIVE BUYING).

MISFORECASTING CONSUMPTION EXPERIENCES

Another reason consumers often fail to select those options that seem best for them is that they often mispredict their satisfaction with their choices. In this section, we discuss examples of prediction errors that can lead to suboptimal decisions.

Consumers' decisions often rely on intuitive predictions about future consumption experiences. Forecasts of how satisfied consumers will be with the consequences of their choices can unfortunately be quite poor. To illustrate this, Kahneman and Snell (1992) asked participants in an experiment to consume a serving of plain yogurt every day for eight days. The participants incorrectly predicted increasing dislike of yogurt, whereas most came to like it more (or dislike it less). Note that this experience of

eating yogurt is quite familiar, suggesting that consumers may fair more poorly when it comes to experiences with which they are less familiar.

Another reason that consumers tend to mispredict which decisions will be most satisfying for them has to do with a distinction between how a consumption episode is experienced as it happens and how it is summarized and remembered in retrospect. When consumers retrospectively summarize a consumption episode, they tend to focus only on a few key characteristics, such as the rate at which the experience became more or less pleasant over time, the intensity of the most extreme sensation, and the sensation at the final moment of the experience (Ariely and Carmon, 2000). Summary evaluations tend to represent only few aspects of the actual experience, and can thus be poor representations of the actual episode. Nevertheless, they are the best predictor of future decisions.

Incorrect but self-fulfilling expectations. Consumers' assessment of consumption experiences are influenced by their expectations, as the latter serve as a standard against which the actual experience is compared. Some expectations are based on widely held but incorrect beliefs, such as the notion that lower prices reflect lower quality (in this example the reality is that the empirical correlation between price and quality is negligible). Interestingly, in some instances, expectations that are incorrect can nevertheless be self-fulfilling.

For example, consumers who paid a discounted price for an energy drink that was said to increase mental acuity, derived less benefit from consuming the product (they were able to solve fewer puzzles) versus those who purchased the same product at its regular price (Shiv, Carmon, and Ariely, 2005). Similarly, Lee, Frederick, and Ariely (2006) asked patrons of a pub to evaluate the "MIT Brew" which was made of regular beer to which a few drops of balsamic vinegar was added. When the ingredients were revealed before participants sampled the brew, few liked it. However, when participants received the information immediately after they had sampled the brew, they rated the beer highly and were more likely to choose the special brew over regular beer. In other words, only when they (incorrectly)

expected the beer to taste badly did it in fact taste that way.

Impact bias. Impact bias occurs when consumers "overestimate the intensity and duration of their emotional reactions to future events" (Wilson and Gilbert, 2005, p. 131). Focalism, the tendency to fixate on certain attributes or events but ignore (or under weigh) others, is one of the causes of the impact bias. For example, Schkade and Kahneman (1998) found that although people's self-reported life satisfaction was similar whether they lived in the Midwest or in California, when asked to rate a similar person living at the other location, they thought Californians would be more satisfied than Midwesterners. This was explained by people's assessments focusing too heavily on the salient qualities of California (climate and cultural opportunities), and largely ignoring other important determinants of happiness. As another example, consumers tend to recall atypical instances (e.g., the worst experience at a restaurant) and may rely on those rare instances in forecasting how they will react to future consumption events.

A related cause of impact bias is a tendency to neglect or underweigh adaptation to changes in circumstances. In a provocative example, Brickman, Coates, and Janoff-Bulman (1978) describe data suggesting that lottery winners are no happier than the average person, and people who became paralyzed in an accident are no less happy than the average person, a year after the dramatic change to their lives. While this example is controversial and may well overstate people's ability to adapt, due to difficulties in measuring and comparing happiness across people, the general point that, people tend to underestimate their ability to adapt, is widely accepted.

Projection bias. Consumer decisions are also influenced by a projection bias, the inability to sufficiently consider how their preferences may change when circumstances become different (Gilbert, Gill, and Wilson, 2002). For example, when in a "hot" state such as hunger or thirst, consumers tend to overweigh the impact of temporary visceral factors on projections of needs and wants (Loewenstein, 1996). For

example, when sexually aroused, men are significantly more willing to engage in unsafe and morally questionable sexual behaviors than they would otherwise consider. (Ariely and Loewenstein, 2006).

IRONIC EFFECTS OF TRYING TO CHOOSE WELL

Consumers' attempt to choose the very best alternative has interesting consequences for their satisfaction. Studies by Wilson *et al.* (1993) suggest that careful consideration of choices can cause consumers to pay more attention to less important criteria, and therefore choose less satisfying options. Ironically, maximization (seeking the best option) can not only result in normatively better decision outcomes (e.g., better paying jobs) but also in more negative subjective evaluations of the outcomes (e.g., lower job satisfaction). The lower satisfaction of maximizers is said to be due to heavier reliance on criteria that seem objectively important rather than criteria that feel important to them, and greater fixation on unrealized options (Iyengar, Wells, and Schwartz, 2006). Furthermore, those who maximize tend to be more affected by upward social comparisons (naturally dissatisfying comparisons to others who are in a better position), and experience more depression and regret.

Sometimes consumers experience buyers' regret, unsettling displeasure with having made a choice. Ironically, this is common with choices over which consumers extensively elaborated (made an effort to determine the very best option). This happens because elaboration can induce feelings of attachment to the choice options, a sense of prefactual possession of those options. When consumers eventually choose, they effectively lose the prefactual ownership of nonchosen options, which evokes negative feelings associated with loss and increases the appeal of forgone options compared to their appeal before the choice was made (Carmon, Wertenbroch, and Zeelenberg, 2003).

Similarly, over time, satisfaction with the chosen outcome can decrease for those consumers who considered alternatives before they chose. Ironically, satisfaction with a randomly assigned option, as well as satisfaction

of consumers who did not consider alternatives, tends to remain comparatively stable (Ritov, 2006). On a related note, when consumers make hyperopic choices (choices emphasizing long-rather than short-term benefits) of virtue over vice, they may experience increasing regret over time because time attenuates emotions of indulgence guilt, but accentuates wistful feelings of missing out on hedonic pleasures, leading to intensified regret (Kivetz and Keinan, 2006) (*see* CONSUMER WELL-BEING).

SUMMARY

Many thoughtful researchers still defend the view that consumer decisions should be considered rational. In contrast, there is a large and growing body of evidence suggesting that consumers are not the *homo economicus* that the classical economic paradigm portrays. Consumers are limited by finite mental capacity; in many situations they have only a sense of what they prefer and must therefore construct their preferences on the fly, and those preferences tend to be contingent on the characteristics of the decision task and context. Consumers' decisions are often swayed by the affect they experience and anticipate and by their predictions regarding future consumption experiences that are often inaccurate. Consumers' attempt to seek utility-maximizing outcomes, ironically, may harm rather than improve their well-being. Although these insights do not yet make up a coherent theory of consumer decision making, they do suggest that *Homo sapiens'* rationality is predictably fallible.

Consumers' decision biases and errors, such as those we review here, can lead to suboptimal decisions. That said, consumers' decisions are often "good enough." In part this is because the heuristics that consumers use are often reasonably effective, and partly since many decisions, including ones in which consumers invest much energy are largely inconsequential, either because the decision is between good alternatives or because the decision is of little real importance. However, in some situations errors can have serious consequences (such as failing to save enough for retirement). The notion of Libertarian Paternalism (Thaler and Sunstein, 2008) proposes that "... knowledge of how people

think be used to design choice environments that make it easier for people to choose what is best for themselves, their families and their society.’’ For example, a simple change to employees’ default decision so that they regularly contribute money to their retirement savings account unless they choose to opt out (instead of the default being not to save unless they choose to opt in) could greatly help combat failure to save enough for retirement. The paternalistic flavor is controversial, though its proponents point out that it does *not* affect the freedom to choose.

In conclusion, the debate over whether and to what extent consumer decisions can be considered rational has spurred a large body of research yielding many insights into how consumers decide. Beyond that, however, approaches such as that of Libertarian Paternalism, using research on customer decision making to help consumers, seem more productive. We hope that future research will not only work toward developing a complete theory of consumer decision making but also shed more light on how this knowledge can be used to help consumers become better decision makers.

motivation and goals

Hans Baumgartner and Rik Pieters

Motivation deals with the question of why consumers do the things they do. It is frequently contrasted with cognition and affect. While cognition refers to the thinking aspect of functioning, and affect to the feeling aspect, motivation deals with the wanting or striving aspect. Two issues are involved: what people want (the direction of motivation) and how much they want something (the force of motivation). Psychological constructs such as needs, motives, desires, wishes, values, drives, and goals all fall within the purview of motivation. It is frequently difficult to distinguish between these constructs precisely, but in general needs and motives are higher level reasons for engaging in a behavior, usually thought to be limited in number so that classifications of human needs and motives can be developed. Desires and wishes tend to refer to lower level wants, often ones whose feasibility may be questionable, with desires being stronger than wishes. Values are high-level ideals that are considered socially desirable by some segments of society, and they may be used as criteria for evaluating objects, events, and behaviors. Drives are hypothetical internal states (often arising from a discrepancy between a desired and actual state and considered to be aversive) that impel people to action and energize behavior. Finally, goals are internal representations of desirable states that people try to attain (approach goals) and undesirable states that they try to avoid (avoidance goals).

In this article, we focus on goals as the central construct of motivation and use the notion of goal in a general sense ranging from relatively concrete aims that provide specific direction for behavior to more abstract purposes (including motives, needs, and values) that imbue subordinate goals with affect. We emphasize the directional aspect of motivation, since involvement (which captures the intensity aspect) is covered in a separate chapter. We start the presentation with a discussion of goal structure and then move to the dynamics of goal pursuit, including both conscious and nonconscious goal setting and goal striving.

THE STRUCTURE OF GOALS

Structural approaches to the study of motivation are well established (see Austin and Vancouver, 1996; Carver and Scheier, 1998; Heckhausen, 1991). These frameworks describe different levels of motivations that people are assumed to have, either in general or in a specific situation, ranging from concrete to abstract motivations, and the linkages between motivations at the same or different levels in the hierarchy in terms of their associative, temporal, conditional, or causal relationships. We begin our discussion with two approaches that are well known but usually not mentioned under the rubric of goals (Maslow's hierarchy of needs and Schwartz's classification of values), although they are closely related since needs and values can be conceived as high-level goals. We then describe means-end chain analysis and its extension to modeling consumer goal structures. We end with a brief discussion of purchase motives.

Needs and values. In general, needs and values are abstract motivational constructs that are linked to the more concrete goals that consumers have in specific life-domains and situations.

Maslow's hierarchy of needs. Maslow (1943) proposed a famous theory of motivation that posits five basic human needs: physiological needs (hunger, thirst, sex), safety needs, love needs (belonging, affection), esteem needs (including both self-esteem based on achievement or independence and esteem from others based on prestige or appreciation), and need for self-actualization. The five needs are hypothesized to be organized into a "hierarchy of relative prepotency" such that lower order needs have to be satisfied before higher order needs can emerge. Applied to marketing, and as described in consumer behavior textbooks, the theory suggests that products are differentially relevant to the five needs (e.g., insurance presumably satisfies the need for safety) and that when appealing to consumers' needs, account has to be taken of where in the need hierarchy a target segment is situated. Among the criticisms of the theory are that the posited hierarchy of prepotency may not be valid and that the theory may not be cross-culturally applicable. Importantly, interest in the basic

2 motivation and goals

needs proposed by Maslow has been growing in recent years, with specific theories and measures being developed for each of them, such as the need to belong (Baumeister and Leary, 1995). In the domain of consumer behavior, Belk, Ger, and Askegaard (2003) provide a rich framework of needs and wants and their connections to consumer passions.

The structure of values. Particularly for purposes of market segmentation, research on values has a long tradition in marketing. Market segmentation aims to identify groups of consumers with similar within-group and different between-group “preferences.” Values are considered such abstract “preferences” that give direction to consumer behavior in a wide range of situations. The most sophisticated framework is Schwartz’s (1992) work on universals in the content and structure of values. Extending Rokeach’s (1973) structural theory of instrumental (lower level) and terminal (higher level) values, Schwartz distinguishes 10 different value types, corresponding to basic human motivations. The value types can be arranged in a circular order to reflect their compatibilities and conflicts. Furthermore, the 10 value types can be grouped into four higher order value domains (roughly four quadrants of a circle): self-enhancement (achievement, power) versus self-transcendence (universalism, benevolence), and conservation (tradition, conformity, and security) versus openness to change (self-direction, stimulation), with hedonism falling between the openness to change and self-enhancement values. Schwartz also constructed an instrument in which participants rate over 50 individual values based on importance, and research using this instrument, involving cultures from around the globe, suggests that the hypothesized structure of values may be universal.

Hierarchical conceptualizations of goals.

Means-end chain analysis. A hierarchical approach to goals, which was developed in marketing and builds on some of the earlier work on values, is means-end chain theory (Reynolds and Olson, 2001; see also Huffman, Ratneshwar, and Mick, 2000). According to means-end chain theory, consumers purchase products

because these products (via their need-satisfying attributes) help them attain certain values. Specifically, product attributes (both concrete attributes such as a car’s horsepower and more abstract attributes such as its sportiness) have certain functional (e.g., being able to drive fast) and psycho-social (e.g., being admired by others) consequences of product use, which ultimately relate to important instrumental (e.g., being independent, imaginative) and terminal (e.g., pleasure, sense of accomplishment) values. The task of marketers is to uncover the salient means-end connections for a product category of interest (via data collection techniques such as laddering), and the resulting hierarchical value map (HVM) can then be used to segment the market and develop positioning strategies that will appeal to the chosen target segments, by emphasizing self-relevant attributes, consequences, and values and the linkages between them.

Goal structures as means-end chains.

Pieters, Baumgartner and Allen (1995) extended the means-end chain approach to the modeling of consumer goal structures (see also Bagozzi and Dholakia, 1999; Baumgartner and Pieters, 2008). The notion that goal-directed behavior is structured hierarchically is a common assumption in research on goals (Austin and Vancouver, 1996). Pieters and his coauthors specifically assume that behavior is usually controlled by a basic-level goal (e.g., losing weight, purchasing a new car) at an intermediate level in the goal hierarchy (which identifies *what* the consumer is trying to do), but that in order to understand behavior more completely, one also needs to know *how* the consumer is trying to attain this goal (the subordinate goal or operation level) and *why* he or she is trying to attain this goal (the superordinate goal or motivation level). Interestingly, the goal hierarchy is closely related to two important goal features, namely, their desirability and importance on the one hand and their feasibility on the other hand. Superordinate goals are relevant for understanding why goals are desirable and important to people, whereas subordinate goals are critical for evaluating the feasibility of goal pursuit. Importantly, the three levels in the goal hierarchy are not fixed but flexible, depending on person and task

characteristics. Different consumers in different circumstances may be guided by goals at different levels in the hierarchy (ranging from wanting to avoid sugary snacks at a rather concrete level to wanting to have a more attractive body or better self-esteem at a very abstract level), and this determines which goals are subordinate and superordinate relative to the basic-level goal.

Consumers' decision making goals and purchase motives. Consumer behavior researchers have considered goals that guide decision making and the processing of other marketing stimuli (e.g., ads). For example, Bettman, Luce, and Payne (1998) proposed four goals (maximizing decision accuracy, minimizing decision effort, minimizing negative emotions during decision making, and maximizing the ease of justification of a decision) that are relevant to decision making. However, surprisingly little research has investigated the motives that underlie consumers' buying behavior (i.e., why consumers make certain buying decisions, not how they make them). Recently, Baumgartner (2010) conducted a comprehensive review of prior classifications of purchase behavior and proposed a new, empirically based typology derived from consumers' categorization of 44 purchase motives. The full typology consists of eight different purchase behaviors corresponding to the eight cells of a $2 \times 2 \times 2$ cross-classification of three orthogonal dimensions: functional versus psycho-social purchases; low versus high purchase involvement; and spontaneous versus deliberate purchases.

As might be expected, purchases that are made spontaneously and entail little effort and care (this includes casual purchases at the functional end and impulsive purchases at the psycho-social end of the continuum) are not well-defined in terms of purchase motives (i.e., buying things more or less mindlessly or based on convenience vs making unplanned or impulsive purchases). Spontaneous purchases that are higher in purchase involvement include promotional purchases (based on functional motives of getting a good deal) and exploratory purchases (based on psycho-social motives of variety, change, and curiosity).

Deliberate purchases made with little involvement comprise repetitive purchases

(characterized by functional motives of loyalty, habit, routine, and familiarity) and hedonic purchases (characterized by psycho-social motives of sensory gratification and simple liking/wanting). Deliberate purchases higher in purchase involvement include extended purchase decision making (based on utilitarian motives such as logical problem solving and a concern with performance, quality, and value) and symbolic purchase behavior (involving psychological motives of wanting to express one's personality and feeling good about oneself and social motives of projecting a certain image, attaining status, and being socially accepted).

CONSCIOUS GOAL PURSUIT

Although they are often intertwined in practice, we distinguish two separate stages of goal pursuit: goal setting and goal striving (Bagozzi and Dholakia, 1999; Baumgartner and Pieters, 2008; Heckhausen, 1991). The discussion of goal setting will focus on the decision to pursue the basic-level goal, where the consumer commits to pursuing a goal. But, of course, goals also have to be set during goal striving at lower levels of the hierarchy, consistent with our earlier discussion about flexibility in means-end chains of goals. Once a consumer has formed an intention to pursue a particular goal (avoiding sugary snacks before dinner or eating less during the week), steps are taken to strive toward the chosen goal. According to Heckhausen (1991), goal setting is a motivational process of deciding whether or not to pursue a given goal, or choosing between conflicting goals, whereas goal striving is a volitional process focused on reaching the desired goal. We emphasize goals that are pursued deliberately in this section, but we touch upon subconscious goal pursuit too.

Goal setting. Sometimes consumers do not set goals themselves but pursue goals that are "assigned" to them (e.g., buying a wedding present using a gift registry, using someone else's shopping list to buy groceries). But often consumers set their own goals, although rarely in a social vacuum. Usually, the goal-setting process is conceptualized as some variant of subjective-expected utility or expectancy-value theory. The notion is that consumers consider

the consequences of pursuing a goal, taking into account both the desirability of the outcomes emanating from goal achievement (“part utilities” or “evaluations”) and the feasibility of reaching the goal and/or the outcomes associated with the goal (“expectations” or “beliefs”). In addition, other influences are sometimes considered as well. A well-known framework, which was originally developed for explaining and predicting volitional behaviors (e.g., buying a soft drink, going out for dinner, voting for a certain candidate) but which has often been applied to goals (e.g., losing weight, donating blood), is the theory of reasoned action or TRA (Fishbein and Ajzen, 1975). According to this theory, behavior is a function of a person’s intention to engage in the behavior, which in turn depends on the person’s attitude toward the act and the subjective norms governing the behavior (i.e., the expectations of relevant others and the person’s motivation to comply with these expectations). Attitudes toward the behavior are determined based on a person’s evaluation of the consequences of engaging in the behavior weighted by the likelihood that the behavior in question will lead to these consequences. Applied to goals, the theory suggests that consumers will form a goal intention (which implies a commitment to reach the goal) if the goal is evaluated favorably by the decision maker (i.e., the outcomes associated with goal achievement are valued highly and it is deemed likely that reaching the goal will lead to these outcomes) and if relevant others are in favor of the decision maker’s goal pursuit.

Bagozzi and Warshaw (1990) reformulated TRA to make it more relevant for explaining goal pursuit. This so-called theory of trying assumes that in the context of goal-directed behavior the relevant dependent variable is consumers’ attempts to reach the goal in question (i.e., trying), that trying is preceded by a conscious decision to try (intention to try), and that intention to try is a function of attitude toward trying, social norms toward trying, and the frequency of past trying. Attitude toward trying depends on considerations of desirability and feasibility involving success and failure at attaining the goal as well as attitudes toward the process of goal pursuit.

Expectancy-values models have typically been applied to single behaviors and goals, but they can be extended to the choice between behaviors and goals by assuming that the behavior or goal with the highest subjective utility and/or the highest behavioral/goal intention is selected. When choosing between multiple goals, conflicts may arise. There are at least three types of conflict: approach–approach conflict (several goals are desirable, such as taking a vacation or having a baby), avoidance–avoidance conflict (one goal has to be adopted, but all choices have undesirable features, such as cleaning up the garage or painting the house) and approach–avoidance conflict (a goal has both desirable and undesirable features, such as spending one’s savings when taking a vacation). Goal conflicts are omnipresent in everyday consumer behavior, but surprisingly little is known about how consumers cope with such conflicts.

Goal striving.

Goal striving with single goals. Once a consumer has formed a goal intention, which implies a commitment to attain the goal, a course of action aimed at reaching the goal has to be planned, the plan has to be implemented, progress toward goal achievement has to be monitored, and if difficulties are encountered, decisions have to be made about whether goal pursuit should be continued, reconsidered, suspended, or abandoned (see Baumgartner and Pieters, 2008).

With simple behaviors and goals, such as those usually studied with TRA, goal striving is not an issue, particularly if the necessary behaviors have been enacted frequently in the past. However, when goal achievement requires a sequence of more complex behaviors, the consumer has to develop a plan for goal pursuit. One tool for planning is mental simulation. Two types of mental simulations have been distinguished in the literature. Outcome simulation involves imagining the consequences of reaching the goal, and particularly anticipated emotional reactions to goal success and goal failure can serve a useful motivational function for energizing goal pursuit. More relevant for planning purposes are process simulations, in which the consumer imagines the steps necessary to reach the desired end.

Prior research shows that engaging in process simulations is more beneficial for goal attainment than engaging in outcome simulations (see Baumgartner and Pieters, 2008).

In a tradition strongly rooted in German psychology (Heckhausen, 1991), Gollwitzer and his associates (e.g., Gollwitzer, 1996) have argued that implementation intentions and an implemental mind-set are useful tools for enacting goal-directed behaviors. Implementation intentions are self-instructions to execute certain behaviors when a particular situation is encountered (i.e., I will do x when situation y arises). They are effective because relevant behaviors are linked to critical situations so that encountering the critical situation automatically triggers the relevant behavior or activates relevant plans in working-memory, which also increases the likelihood of enacting the intention. In a similar way, an implemental mindset has been found to facilitate the enactment of goal-relevant behaviors because instead of deliberating the pros and cons of potential courses of action (which is characteristic of a deliberative mindset), the consumer focuses single-mindedly on the execution of behaviors necessary for goal achievement, and doubts about feasibility and desirability are put aside.

Consumers need to self-regulate during goal pursuit (i.e., they have to stay focused on striving toward the goal and not be distracted by momentary temptations, and they have to be able to resume goal pursuit after an interruption). Following Baumeister (see Baumeister *et al.*, 2008, for a recent review), self-regulation involves monitoring goal progress with regard to standards and it requires self-regulatory strength. Since people's capacity for self-regulation is limited, engaging in self-regulation is ego-depleting. Various tasks have been shown to result in ego depletion, including making choices between consumer products and trading off quality and price. Furthermore, ego depletion has been demonstrated to make it more difficult for consumers to control their eating and spending, among other things, and it may lead to the use of simplistic decision strategies such as choosing options based on the attraction effect.

The final step of goal striving is the evaluation of goal achievement. If the goal is an outcome goal

("buying a Porsche sports car"), goal pursuit is terminated when the goal has been reached (i.e., the consumer has purchased the car). However, when the goal is a process goal ("learning to drive a Porsche like the pros"), goal pursuit consists of a continuous process of goal monitoring and involves attempts to either ensure goal progress or maintain adherence to appropriate standards.

If the consumer encounters difficulties during goal striving, several coping strategies are available. These include putting additional effort into goal striving, revising the initial plan, suspending the goal, or abandoning the goal. Research has shown that emotions play an important role in alerting people to those aspects of goal pursuit that require attention, and emotions are also an important consequence of goal success and goal failure (see Baumgartner and Pieters, 2008, for details).

Goal striving with multiple goals. In practice, consumers usually do not pursue single goals, but have to juggle multiple goals. One question is how they accomplish this multiple-goal pursuit over time. Will they first pursue one goal, and then move on to the next, in an orderly sequence? An integrative model of the dynamics of multiple-goal pursuit was recently proposed by Louro, Pieters, and Zeelenberg (2007). These authors argue that, when several goals compete for resources (i.e., the goals do not conflict intrinsically, but compete for the same resource pool), effort allocation to the focal goal is a joint function of the valence of goal-relevant emotions and people's proximity to the goal. When goal progress is slower (faster) than expected and people therefore experience negative (positive) emotions, less (more) effort will be allocated to the focal goal when goal attainment is distant, whereas more (less) effort will be allocated to the focal goal when goal attainment is near. Furthermore, the proposed effects are mediated by people's expectancies of success, such that either positive emotions (when the goal is distant) or negative emotions (when the goal is close) lead to moderate expectancies of success, which maximize effort allocation relative to situations of low or high expectancies of success. In other words, positive emotions have a facilitating effect on goal pursuit when people are far away from the

goal (“It is still a long way, but I’m doing well”), whereas negative emotions encourage goal pursuit when people get close to the focal goal (“It’s so close, but I’m doing badly”). The reason is that these are the situations in which goal attainment is uncertain but plausible and allocation of effort promises to further goal progress. In three studies involving goals that compete for consumers’ attentional and time resources, such as dieting and studying, Louro, Pieters, and Zeelenberg (2007) found support for these predictions.

Regulatory focus theory in goal pursuit. A motivational theory that has had a substantial impact on consumer research is regulatory focus theory (e.g., Pham and Higgins, 2005). The theory distinguishes two types of regulatory orientations. When people are in a promotion focus, they are concerned with accomplishments, the relevant self-guide is the ideal self (one’s hopes and aspirations), and behavior is sensitive to the presence and absence of positive outcomes. In contrast, when people are in a prevention focus, they are concerned with safety, the relevant self-guide is the ought-self (one’s duties and obligations), and behavior is sensitive to the presence and absence of negative outcomes. Research has shown that, consistent with these different outcome foci, promotion-oriented consumers have a preference for products signaling luxury and technical innovation, whereas prevention-oriented consumers assign greater value to safety and reliability. In addition, consumers prefer decisions for which there is a match between their regulatory orientation and the means of goal pursuit (value from fit). This occurs when a goal is pursued in an eager fashion (taking chances and avoiding missed opportunities) under a promotion orientation or in a vigilant fashion (being careful and avoiding mistakes) under a prevention orientation. Because of the dual emphasis of the theory on outcome value and value from fit, the theory is relevant for both goal setting and goal striving and has proven useful in areas as diverse as message framing and persuasion, emotional reactions to past and future decision outcomes, and cultural differences in conceptions of the self (independent vs. interdependent self-views).

NONCONSCIOUS GOAL PURSUIT

Thus far we have emphasized consumers’ conscious pursuit of goals when a goal is set deliberately and consumers are fully aware of their attempts to strive toward the goal. Many important consumer behaviors are consistent with this process, such as when somebody decides to buy a new car or books a flight to spend the holidays with family. However, it is possible for goals to be activated outside of consumers’ awareness, and even the process of goal striving may occur subconsciously. The idea of subconscious goal pursuit is an old one and in the 1950s and 1960s the term *motivation research* actually referred to the study of the hidden motives underlying purchase and consumption. Motivation research fell into disrepute and except for occasional forays into subliminal persuasion (following the journalistic report of James Vicary about the effectiveness of subliminally flashing “eat popcorn” on a movie screen), researchers showed little interest in nonconscious influences on consumer behavior. However, recently there has been a new surge of interest in automatic influences on human behavior in general and consumer behavior in particular (see Bargh, 2002; Chartrand *et al.*, 2008).

According to this perspective, processes that are functionally similar to goal setting and goal striving can occur without conscious awareness. First, cues in the environment, which have become strongly associated with certain goals through past exposure, can activate goals automatically. In laboratory studies, nonconscious activation is usually achieved through subliminal priming, in which participants are exposed to goal concepts so briefly that they are not consciously aware of the priming stimuli, or supraliminal priming, in which participants are exposed to goal concepts in the context of an ostensibly unrelated study. The real-world analog of such manipulations would be situations in which the consumer happens to get exposed to symbols that are associated with certain goals (e.g., prestige and status when seeing a store sign for Nordstrom). Prior research shows that the nonconscious activation of a goal can indeed affect consumer choices (e.g., priming prestige vs thrift increases the choice of a higher priced product).

Second, not only can goals become activated nonconsciously, but the entire process of goal pursuit can occur outside conscious awareness. The reason is that the steps necessary to reach the goal (the means of goal achievement) have been automatized and once the goal is activated, the associated action plan is enacted as well. Furthermore, this nonconscious goal pursuit exhibits many of the features characteristics of conscious goal striving. When a goal is unfulfilled, motivational strength increases over time, whereas when a goal has been achieved, motivational strength decreases. In addition, similar to conscious goals, nonconscious goals increase people's persistence when there are obstacles to goal achievement, and they encourage resumption of goal-directed behavior after interruption. For example, in the study in which either a prestige or thrift goal was primed, choice of the higher priced product as a function of the prestige prime increased when the time interval between the goal priming and the choice task was longer. Overall, there is now convincing evidence that at least relatively simple goals can be activated automatically and that the ensuing goal pursuit can also occur without consumers' conscious awareness.

CONCLUSION

Despite the importance of motivation and goals for understanding consumer behavior, the wanting or striving aspect of psychological functioning was not at the forefront of research for many years. However, motivation has experienced a renaissance recently, and goal concepts, both conscious and nonconscious, are now employed quite frequently in published research. We hope that this renewed emphasis will motivate additional research to deepen our understanding of consumer behavior, and that the current essay contributes to this goal.

consumer expertise

Eric M. Eisenstein

INTRODUCTION

Consumer learning has been a focus of research in models of consumer behavior since the early days of marketing as an academic discipline. Research on consumer knowledge and expertise is more recent (e.g., Alba and Hutchinson, 1987), but both streams of investigation share a heritage within cognitive psychology. However, within psychology, the topics of learning and expertise have had quite different research foci. Models of learning have been explored in tasks ranging from those performed by animals (e.g., pigeons and rats) to complex skills available only to humans (e.g., reading, driving, language acquisition). Many of the paradigms that have been used to investigate learning involve laboratory experiments in which subjects are “trained up” to be expert in some (usually fairly simple) task. Thus, in psychology, research into learning has largely focused on the earliest stages of learning – moving from zero or near-zero expertise to some greater level. Cognitive psychologists have traditionally viewed expertise as the end result of many years of learning and practice, and the paradigms used to identify expertise have tended toward observational studies in which learning has occurred naturally over many years rather than in the laboratory (Chi *et al.*, 1988; Shanteau, 1988a). In contrast to cognitive psychology, in consumer research neither expertise nor learning has received extensive attention, and the paradigms that have been used have not typically been the same as those used in cognitive psychology. Among other differences, in consumer research learning and expertise have generally been treated as closely related to each other.

What is expertise? Historically, there has been little agreement on the definition of expertise, which has hampered research. The layman’s conception of expertise generally suggests broad-based, superior problem solving skills. This conception was shared by early researchers, who conceived experts as general problem solvers, but this formulation was short-lived,

because it was soon discovered that learning experiences are bound to a specific environment, and that the superior performance of experts is tied to a domain. Initially in the concrete domain of chess, and then in many other domains, it became apparent that expertise depends critically on detailed, domain-specific knowledge, and that transfer of expertise is remarkably more difficult than expected. Therefore, when we discuss expertise, researchers are in agreement that we are really discussing human performance in a specific environment. However, there is still considerable disagreement on the definition of expertise as a construct.

Shanteau’s (1988a, 1988b) Theory of Expert Competence remains the most widely accepted definition of expertise, and it provides a road map for examining consumer expertise. For the moment, let us assume the existence of a group of experts, and defer the thorny question of how one would determine who is a bona fide expert. Given the existence of at least some experts, competence will be based on five factors: domain knowledge, psychological traits, cognitive skills, decision strategies, and task characteristics. From the point of view of marketing, these characteristics can be mapped onto typical situations faced by consumers to determine the likelihood of achieving expert level consumer performance.

Adequate *domain knowledge* is a prerequisite for expert performance. It is likely that familiarity (repeated experience with the product or category) is necessary to develop adequate domain knowledge. However, it is obvious that mere memorization of facts in laundry list fashion is insufficient to achieve expert decision making performance. This is because accuracy depends critically on the linkages between stored facts, and creating and learning the linkages among stored facts is a kind of metaknowledge that is not simply declarative. Alternatively such linkages could be thought of as a separate skill requiring enrichment of the mind’s ability to identify similarities and patterns, and to use that similarity function to recruit decision-relevant facts from long-term memory.

Experts require specific *cognitive skills* in order to achieve high levels of performance. The exact composition of these cognitive skills depends on the specific task. For example, the

2 consumer expertise

task may require retrieving items from a large number of previously stored cases, the ability to perform well under pressure, or the ability to quickly recognize patterns, among other skills. Clearly, aspiring experts will have an advantage on tasks which load on these skills to the extent that their cognitive abilities match the task requirements. In addition to cognitive skills, expertise requires mastery of specific *decision strategies*, which help experts to overcome cognitive limitations. Within consumer research, considerable research effort has been devoted to the simplifying heuristics that consumers use to consider, eliminate, and choose among presented options, and how decision strategies vary with various task characteristics such as amount of information, number of attributes, number of options, and so on. Payne, Bettman and Johnson's (1993) adaptive decision maker is perhaps the classic example of this type of research (see CONSUMER DECISION MAKING). Research in this stream has generated robust findings that demonstrate that novice consumers frequently ignore large amounts of relevant information and are susceptible to various decision biases that arise as a result of heuristic processing. Payne *et al.*, and other researchers working within their effort-accuracy paradigm, explicitly exclude experts from consideration, and there has been little additional work done to determine what modifications to the basic theory would be necessary for expert consumers.

The role of *task characteristics* is often overlooked in the study of expertise, both in psychology and in marketing. Many have argued that characteristics of the task are critical in determining whether there will be any bona fide experts in the domain (i.e., people who are consistently superior). A common observation is that in some domains experts perform at very high levels, but in other domains, performance is not significantly different from novices. In general, task characteristics that predict good performance include repetitive tasks that are based on static, agreed-upon stimuli, with timely, veridical, feedback available, and a stationary underlying model, in which the unmodelable error in the environment is low. Task characteristics that suggest poor performance with little evidence of objective expertise include dynamic stimuli or stimuli

with little agreement about which are important, nonstationary underlying processes, where feedback is either unavailable, nonveridical, delayed, or ambiguous.

Shanteau proposed that experts also possess certain *psychological traits*, such as "self-presentation – the creation and maintenance of a public image," (Shanteau, 1988b). This proposition is controversial, because there are charlatans and hucksters who are surprisingly adept at the art of self-presentation. However, surprisingly, such traits may be highly relevant when discussing consumer expertise. This is because most people have a friend or acquaintance who knows "everything" about cars, computers, stereos, food, stocks, or other common consumer goods, and one characteristic of such "consumer mavens" is that they are able to maintain (and perhaps develop) the self-presentation of expertise (see OPINION LEADERSHIP AND MARKET MAVENS). Consumer research has not extensively investigated the role of these consumer experts, except in thinking about them as early adopters in Bass and similar diffusion frameworks.

Applying this framework to consumer expertise, we should expect the development of expertise across a wide variety of consumer tasks. For example, many consumers buy "collectables." Some collectable purchases are priced using a typical retail take-it-or-leave-it formats. However, many collectables are sold at auction (e.g., on eBay) and others are sold at yard sales, flea markets, and other similar venues, which are not fixed price settings. Under such circumstances, we would expect that consumer expertise would develop, with some consumers able to accurately value objects within their domain of expertise. Similarly, experienced shoppers are likely to develop a reasonable sense of where to go for the cheapest product, if it is commonly purchased (though store choice is not usually determined by a single good). In other circumstances, it is unlikely that consumers will develop substantial expertise. For example, people infrequently negotiate over automobiles, little feedback is available to the consumer after the deal, and the relevant attributes change over time. Therefore, we would expect very little expertise to develop among ordinary consumers in this market.

In many domains in which expertise has been studied, expert participants are typically at the highest levels of learning or achievement within the field. By contrast, in consumer research, investigations of expertise have generally involved comparisons of more knowledgeable and less knowledgeable consumers without requiring that the more knowledgeable consumers be experts in the sense of representing the highest attainable levels of knowledge (e.g., grand masters in chess, professional judges of agricultural products, medical doctors, and meteorologists). This focus on “relative” rather than “absolute” expertise is natural because many (arguably most) important problems in consumer behavior involve the very earliest stages of learning from experience (e.g., the adoption of innovations, transitions from trial to repeat purchases, and differences between light and heavy users). Thus, the emphasis in this article is on the integration of learning and expertise on the effects of relative differences in consumer knowledge on questions of consumer behavior.

BENEFITS AND COSTS OF CONSUMER EXPERTISE

One reason that the definition of expertise remains open and controversial is that there are starkly conflicting research results associated with the study of experts across domains and research paradigms. Among decision scientists, the results of many carefully controlled studies of experts (as defined by credentials, schooling, years of experience, and peer consensus) paint a dismal picture of expertise, revealing a robust finding that experts are no better than novices in objective performance (see Meehl, 1954, for a seminal and comprehensive overview). These findings stand in sharp contrast to the findings of cognitive psychologists. In psychological research on experts, the robust finding is that experts dominate novices in almost every aspect of cognitive processing, such as measures of cognitive structure, memory or recall for facts, analytic processing, information use and selection, inference, problem solving strategy choice, effort and automaticity, ability to deal with complexity, and elaborative reasoning. Camerer and Johnson (1991) dubbed these

contrasting results the “process–performance paradox” (i.e., experts dominate on tests of cognitive process, but fail to achieve better results). Before attempting to resolve this paradox, it will be useful to review the benefits and potential costs of expertise.

COGNITIVE STRUCTURE

Cognitive structure refers to the way in which factual knowledge is organized in memory. As product familiarity increases, especially from nonuser to user of a product, cognitive structure is acquired (*see* THE ROLE OF SCHEMAS IN CONSUMER BEHAVIOR RESEARCH). The most common forms of cognitive structures studied in consumer research are based on psychological research into naturally occurring categories, because product categories, consisting of brands, products, and attributes are generally learned from experience in the same way that naturally occurring taxonomic categories are learned. There are a number of widely accepted theories that are borrowed from cognitive psychology in such research. First, most product categories behave similarly to what Rosch and her colleagues (Rosch *et al.*, 1976) termed “basic level categories,” meaning that objects (products) are named at this level and that people can identify objects as belonging to a basic level more quickly than those belonging to a nonbasic level. The essential characteristic of basic level categories is that, at the basic level, within-category similarity and between-category dissimilarity are maximized (e.g., the basic level category is “bird,” not the subcategory “raptor” or “finch,” and also not the supercategory “vertebrate” or “animal”); *see* CONSUMER CATEGORIZATION. It is easy to see how typical markets encourage classification structure at the basic level: insofar as product categories are defined as collections of substitutes that compete with each other to fulfill the same consumer needs, it is natural that such products will be quite similar to each other, and dissimilar to products that do not fulfill those needs. As expertise increases, knowledge about subordinate categories increases and information at this level is processed as efficiently as at the basic level (thus, ornithologists would be almost equally fast when classifying “raptor” or “finch”). There has been little research in

4 consumer expertise

marketing to determine the extent to which the most typical products within a category are also the best products, or how this perception varies with expertise. However, marketing researchers have reached conclusions similar to those of cognitive psychologists, in that expert consumers have substantially different and more elaborate cognitive structures than novices, as well as the attendant advantages in processing speed.

MEMORY

One common characteristic of experts in all domains is better memory for domain-relevant facts, which is at least partially because of experts' more elaborate, better-organized, and differentiated, cognitive structures. Classic studies of chess experts showed that grand masters could remember game configurations far better than novices, but only when shown board configurations that could be obtained in real games (Chase and Simon, 1973). Similar results have been obtained in a wide variety of fields, providing strong evidence for the superiority of experts over novices in recall. Although a very small amount of this research has been specifically called consumer research (or conducted by consumer researchers), most investigations have used consumer markets or activities to define the continuum of expertise. For example, there have been extensive studies on expert versus novice players of games (e.g., chess, bridge, and go), sports (e.g., baseball, basketball, football, figure skating, and field hockey), as well as studies of hobbyists who follow these sports (i.e., people who follow baseball or basketball carefully, especially statistics related to the game). In consumer research, researchers have demonstrated the superiority of expert recall for attributes, attribute values, and the relationships between them. Studies by researchers in cognate fields have replicated the memory superiority effect in business and academic contexts, such as computer programming, mathematical proofs, physics problems, and medical diagnosis. Memory superiority, almost by definition, leads to more completely and perfectly informed consumers, and ought to improve decision making.

In general, research demonstrates that expert consumers are better able to process new information about products, are therefore more resistant to the biasing effects of advertisements, and as a result, they make objectively better decisions (however, this is not universally true, see the section Negative Consequences of Expertise).

ELABORATIVE THINKING

In addition to better organization and memory for information acquired directly from product experiences, experts sometimes exhibit higher levels of reasoning and problem solving within their domains of expertise. The most frequent, important, and researched type of problem solving that occurs within the context of consumer expertise is the ability to infer the ultimate benefits and costs of a product based on its objective features and technical specifications, which leads to the concomitant ability to use these inferences to solve the problem of satisfying specific needs. For example, consumers are constantly faced with the task of evaluating products' attributes and determining the appropriate weights to apply to the attributes in order to maximize the consumption utility of a specific usage occasion. The research consensus is that experts are considerably more accurate than novices in making feature-to-benefit inferences, whether for themselves or when serving as an agent for another party. Expertise also reduces perceived complexity, increases the utility of the ultimate choice, and experts extract differentially more utility in complex situations than novices.

OTHER POSITIVE EFFECTS OF EXPERTISE

One surprising finding in the research on expertise is that, contrary to conventional beliefs, experts use approximately the same number of cues, or pieces of information, in their reasoning as novices. However, what information is used varies significantly between experts and novices. It appears that for many tasks, variable selection is more important than the weighting assigned to those variables. As a result, in many fields, especially consumer oriented decisions, experts perform better than novices in choosing what information to examine, where to invest time

in searching for additional information, and in making an ultimate decision.

In addition to better choices of attributes or cues to examine, experts also use substantially different problem solving strategies than novices. Among other major differences, novices tend to reason backward from a goal, whereas experts tend to classify the problem as a certain type, and then proceed forward using tools that are appropriate for the identified problem-class. This effect is particularly evident in concrete domains such as solving math, physics, or computer programming problems, as well as in games such as chess, bridge, and go. However, these games probably represent a good analogy for many types of consumer decision making. As in games, many consumer decisions are made from a strongly constrained set of options, where specific rules reduce the combinatorial space to a far smaller number (e.g., cellular phones). Hence, we should expect that expert consumers are able to reason forward rather than backward, and that this change in reasoning strategy at least partially accounts for the robust finding that expert consumers are better able to choose products appropriate to the usage situation (see the section Elaborative Thinking).

Experts have overlearned many of the skills they use. This is a double-edged sword. On the one hand, overlearning leads to automaticity, reduced effort, reduced perception of complexity, and a general reduction in effort with little or no loss of accuracy. However, automatic processing has downsides, including attentional blindness to possible environmental changes (see HABIT IN CONSUMER BEHAVIOR elsewhere in this volume, and the section Negative Consequences of Expertise).

NEGATIVE CONSEQUENCES OF EXPERTISE

When humans believe that they have learned something, they become more confident in their answers (whether or not anything has in fact been learned in the sense of objective measures of accuracy). Unfortunately, it appears to be a nearly universal truth that the rate of increase in confidence outstrips the actual increase in accuracy (it may be noted that this does not prevent experts from being more accurate than novices, merely that there is an interaction such that they

are frequently more overconfident). The correspondence between actual accuracy and confidence is called *calibration*, and most studies have found experts to be at least as poorly calibrated as novices (see Alba and Hutchinson, 2000, for a comprehensive review). This effect has been replicated in medicine, law, psychology, sports, and among undergraduates (who were assumed to have more expertise in their major than in other areas). The notable exceptions to this finding have been in examinations of professional meteorologists and world-class bridge players, leading some to speculate that large numbers of repetitions with immediate outcome feedback is necessary for calibration to be improved by experience. However, as a stylized fact, acquisition of expertise does little to reduce the overconfidence that plagues most human decision making. Given that consumer decision making environments rarely feature the type of task characteristics associated with meteorology or bridge (i.e., neither large numbers of repetitions nor immediate outcome feedback), it seems likely that consumer experts will exhibit overconfidence and lack of calibration, perhaps in greater amounts than novices.

Confidence and calibration are particularly important in the consumer domain, because confidence has been shown to be a strong predictor of consumer preferences and choice, and confident consumers are less susceptible to manipulation by advertising and other marketing techniques. The fact that confidence and learning become increasingly disassociated as expertise (and experience or familiarity) increases is therefore problematic. In particular, overconfidence among consumer experts is likely to slow the diffusion of new information into the marketplace to the extent that novice consumers rely on word of mouth and the opinions of expert consumers as a major source of prepurchase information (e.g., in high tech industries). Furthermore, the increased reach of individual experts' opinions that has resulted from Internet-based social networking is likely to make word of mouth more important in novices' decision making. Thus, social networking will likely exacerbate any negative effects associated with overconfidence.

Another possible negative consequence of expertise is that it may inhibit the spontaneous recognition of a change in the underlying environment under some circumstances (Wood and Lynch, 2002). For example, if an expert consumer has learned that attributes *a*, *b*, and *c*, are associated with some positive outcome, it may be more difficult for such an expert to detect the fact that *c* has become a negative, or merely less positive than it used to be. On the other hand, experts still appear to dominate novices in speed of learning, adapting to, and recognizing such changes if they are cued that a change may have occurred. Owing to the interaction, any potential disutility of expertise depends on the relative levels of cued and uncued changes in the environment – a topic that is essentially unstudied.

EXPLAINING EXPERT PERFORMANCE

Given the slow computational speed of the human brain, it is reasonable to ask how experts are capable of bringing relevant information, inferential techniques, and other specialized skills to bear on problems as quickly as they are observed to do.

Computation rate versus knowledge base size.

Experts are called upon to process complex decision inputs and to make accurate decisions quickly. There are two general ways to approach this problem: retrieval from memory and search. Retrieval from memory is a fast and relatively effortless process for humans: conditional on a match between the current situation and a past situation that has been stored in long term memory, retrieval is rapid and automatic. If it is discovered that there is no good match in memory, however, a slower “computational” or exhaustive search through the space of possible answers ensues to discover an appropriate course of action. Search is effortful and slower, but it is the foundation of general problem solving ability. There is an obvious trade off between knowledge and search. Building an extensive database of cases and committing them to memory is time intensive, though the costs can potentially be spread out; learning procedural knowledge is frequently easier, but the actual computation is more effortful. The retrieval-search continuum

represents the difference between the *cost of learning*, which is borne in the past, and the *cost of thinking*, which is incurred at the time of decision (Shugan, 1980; Eisenstein, 2002).

A robust finding is that expert performance is largely based on retrieval, not search. Experts pattern match and recall from memory, whereas novices tend to think extemporaneously. Therefore, the cost of expertise is a high cost of learning, not a cost of thinking (indeed, automaticity may reduce the cost of thinking!). This finding provides the explanation for why expertise has been found to be domain-specific and difficult to transfer to even analogous problems: the stored cases and exemplars in memory are strongly bound to a particular domain. Moreover, even for analogous problems, relevant examples must be recalled and matched, and the associative “recall key” is equally, or more strongly, bound to a domain. To provide an idea of the power of retrieval as compared to search (and therefore of experts’ decision making vs novices’), we can examine the case of chess, which has been called the *drosophila* of expertise. In chess, humans can process approximately one node (essentially a potential move) per second. By contrast, computers can search nearly 200 million nodes per second. Yet, human experts compete on nearly equal terms with such computers, in spite of a hundred-million-fold difference in processing speed. In order to accomplish this feat, it has been estimated that human experts store 50 000 to 100 000 positions in memory, and simultaneously possess a highly developed sense about when each is applicable. Although the number of stored exemplars may differ by domain, it is quite likely that similar effects would be revealed in many other areas of human expertise, from appraising collectables or houses to estimating the price of cars. For consumer experts, it seems likely that similar “databases” of facts, usage occasions, outcomes, and so on, are stored by experts, whereas novice consumers must attempt to reason their way through at the time of decision. However, little research attention has been given to investigating this question.

Learning to be an expert. Expertise cannot occur without learning. As discussed previously, a large knowledge base that allows experts

to draw on a larger store of memorized facts is one difference that explains a portion of expert-novice performance differences. The large knowledge base allows experts to employ a case-based judgment strategy. Case-based strategies rely on the impressive human ability to automatically and relatively effortlessly judge similarity between cases. Using such a strategy, an expert compares the attributes of the current case to those stored in long-term memory, and the expert then reports a judgment for the current case that matches the judgment made in the stored case (or a weighted average of prior responses). This strategy has been shown to be common in fields such as law, medicine, automobile and other fault diagnostics, and chess. It is likely to be employed by experts in other domains as well (e.g., case studies are often used in MBA programs, and it is likely that business people use them as well). Case-based strategies are most useful and accurate in highly predictable environments because, in such environments, any individual case will be quite similar to the stored cases to which it is most similar. Using a case-based strategy, individual differences in the number of cases stored in long-term memory and in the veridicality of the similarity metric will underlie differences in observed expertise. The utility of a large set of stored cases begs the question of how novices accrete these cases in memory en route to becoming an expert. Cases can be observed and committed to memory either through deliberate instruction or from experience, and experiential learning may be intentional or incidental.

Instruction is one of the most common ways that people become expert in a domain. For example, someone can take a course on computer programming and master recursion, or a doctor can attend medical school and become better than a novice at diagnosis. Instruction tends to be the primary path to skilled performance in most scientific and technical fields, which makes sense because these are fields in which "practice makes perfect" and in which there is an established base of facts and relationships to be mastered. Experience is another route to skilled performance, though the literature suggests that it is a much less successful path than instruction (see Klayman, 1988 for a comprehensive review). When learning from experience, the

norm is that people identify small numbers of cues and utilize simple rules for combining them. However, occasionally people do appear to learn complex rules from experience as they become expert. For example, it has been shown that there exist experts at predicting the outcome of horse races, and these experts used complex configural rules, learned from experience, that they could not articulate (and their expertise extended to making money at it).

Unfortunately for consumers, most consumer expertise is likely to be gained through experience. There are likely some exceptions where learning about a product category through a guide or magazine article is the norm. Learning from experience is more difficult than learning by instruction, and the likelihood of developing expertise from experience is greatest when the general conditions that have been identified for the development of expertise are satisfied. First, the outcome and the feedback relating to that outcome should be unambiguous. Second, the feedback about whether the prediction was correct should be immediate (delayed feedback is not particularly useful). Third, the number of experiences should be "large." For example, learning how to appraise used cars is a skill that is likely to be learned from experience. However, in order to learn to accurately price used cars, the would-be expert must observe hundreds or even thousands of used car auctions, each time comparing his predicted price to the actual selling price, updating and adding to his knowledge base. For consumers, these characteristics can be used to predict domains in which substantial expertise will develop, but these predictions are complicated by substantial heterogeneity in the availability and quality of feedback. Many consumer tasks provide ambiguous feedback, subject to a substantial delay between purchase and consumption (and therefore feedback), and a modest number of consumption opportunities. Other consumer decisions have the opposite characteristics. Moreover, for some types of feedback, such as the utility associated with using the product, it might be easy to obtain feedback that is well-suited to the development of expertise, but it might be difficult to pay appropriate attention to the feedback, as when consumption occurs in a distracting environment such as a party, or with children screaming. Because

the focus of research in marketing has been almost exclusively on studying people, rather than decision environments, we know little about the quality of feedback that is encountered by consumers.

Regardless of the quality of feedback, extensive research in both psychology and in marketing has demonstrated that raw experience or degree of familiarity is a poor predictor of expert performance. Some of this effect is owing to a subtlety in the definition of “experience.” Most people think of experience as the amount of time spent “doing” an activity. For example, if someone had shopped for tennis racquets over a 20-year period, they would say that they had 20 years of experience shopping for racquets. However, experience is necessary but not sufficient to lead to improved performance. The critical link between experience and expertise appears to be the intention to learn from the experience, and at a more granular level, the precise goal associated with learning (Eisenstein and Hutchinson, 2006). This linkage occurs because learning goals define what constitutes feedback (particularly important in real-world environments in which the feedback is ambiguous), and intentionality directs attention to feedback and to discrepancies between the intended and actual outcomes. In the expertise literature, experience gained with the explicit goal of identifying discrepancies between one’s mental model and the true state of the world is called *practice*, and in contrast to mere experience, time spent practicing is highly correlated with objective performance. In situations in which practice is not the norm, learning may still occur incidentally or unintentionally. This type of learning can be extremely powerful, and may lead to accurate judgments in relatively simple, deterministic domains, but it is generally not adequate for the development of expertise in most environments. Moreover, one of the hallmarks of incidental learning is the inability of subjects to articulate their reasoning process, which limits its usefulness in many decision problems.

In the development of consumer expertise, there remains an open question as far as how often consumers practice their buying skills, as opposed to simply experiencing outcomes. Certain consumer skills may be subject to

substantial deliberate practice, for example searching for the lowest price on the Internet. However, some consumer activities are almost never practiced (e.g., learning attribute-price relationships in a grocery store, in which we have found that people cannot recall prices 30 seconds after purchase, much less at the time of consumption). There may also be individual differences in the degree to which identical consumer experiences are viewed as opportunities for learning, practice, and skill development (e.g., when dining out, some people are careful to taste wine with the intention of learning an attribute-quality relationship, whereas others are content simply to experience the wine).

Incentives. In laboratory studies of experts, feedback is frequently combined with an incentive to get the answer correct. In the real world, such incentives take the form of arbitrage opportunities, promotions, or other payoffs for getting the answer right. Neither the mere existence of feedback nor the addition of incentives is sufficient to guarantee the development of expertise, and in some cases, incentives reduce the rate of learning. In many consumer environments, the incentives are obvious (saved money, increased utility through superior match between product and usage). Most people, including most economists, assume that incentives will increase effort, motivation, and persistence. However, incentives are not universally helpful, and additional effort does not always result in improved performance or learning. The effects of incentives are complex and vary depending on characteristics of the task and the learning environment. In general, incentives improve performance in tasks where increased effort is likely to result in better performance, such as memory or recall tasks, clerical tasks, and motor tasks (the latter two because they are otherwise boring, and incentives help to maintain effort). Since incentives primarily affect motivation, incentives are unlikely to have an effect when intrinsic interest in the task is high. Perhaps surprisingly, incentives frequently degrade performance in tasks that require flexibility in thinking and in tasks for which it would be better to rely on automatic processes (e.g., “choking” in sports, test anxiety). Moreover,

incentives have been shown to exacerbate large classes of documented cognitive biases (e.g., representativeness, accessibility) and perceptual illusions. However, research has demonstrated that additional motivation to perform well is helpful mainly in tasks where little cognitive effort is required. Additional research has shown, however, that if incentives are too “exacting,” meaning that subjects are strongly penalized for errors, then incentives reduce performance and the rate of learning. Thus, as in the case of feedback, the specific characteristics of decision making tasks are critically important in making predictions about the relationship between incentives and the development of expertise. Since incentives primarily affect motivation, one could hypothesize that incentives would be most important for the quotidian tasks consumers encounter. Perversely, however, these everyday tasks are likely to be the least important in people’s lives, and also less likely to have significant incentives associated with them. Finally, in the development of consumer expertise, there are always the incentives of increased utility and decreased cost, but there has been little or no investigation of whether consumers perceive their decision milieu in these economic terms.

CONCLUSIONS AND FUTURE RESEARCH

At the outset, the question of whether there are bona fide experts was deferred, as was a satisfactory explanation for the process-performance paradox. Decision scientists have purportedly shown that experts are not superior to novices, and that experts are frequently bested in accuracy by “simple linear models.” These facts are so entrenched in the decision science literature that some researchers have argued that “all anyone needs to know is which variables to look at, and then how to add” (Dawes and Corrigan, 1974).

In spite of the dismal view of experts painted by decision scientists, there are good reasons to believe that bona fide experts do exist, both in the consumer domain and in other fields that have been the frequent whipping boys of researchers (e.g., medicine). Although the evidence is mixed, taken as a whole it generally supports the superiority of experts over novices. This statement is not without caveats. The common conception

of expertise is sociological – an expert is anyone agreed to be an expert. This definition is directly related to Shanteau’s notion of self-presentation, and his argument that members of a field should determine who the experts are by acclamation. It may be argued that the *sine qua non* of expertise is objective accuracy. The risk with this definition is that it is tautological: experts are found only where there is demonstrable superiority in accuracy. Although this is literally true, an accuracy requirement is actually much more stringent, and more useful, because it rules out the possibility of expertise in the absence of well-defined outcomes, agreed upon by independent observers, and a gold-standard of “correctness.” This requirement has the effect of eliminating the concept of expertise from many fields, because in many domains, such a standard does not exist, and it may not be possible to construct one. This is particularly true in fields for which conditions that are believed to encompass a “spectrum” of manifestations (depression, autism, Asperger’s, schizophrenia), as well as for matters of taste (what does it mean for a wine or a meal to be “good”? or one operating system to be “easier to use” than another?). In both cases, what would serve as the standard of accuracy? Similarly, this definition would exclude (correctly, it may be argued) anyone from being an expert astrologer or alchemist.

In future research, the findings of lack of expert performance should be challenged. Although there have been many studies conducted by decision scientists, the vast majority have used a small set of experimental paradigms. The set of experimental paradigms should be expanded. Moreover, many (if not most) studies that have examined expert-novice differences have done so in extremely limited contexts. For example, an expert and a novice might be asked which of two options is a better match for a certain usage situation, or which of two diseases is the correct diagnosis. Such tasks minimize experts’ advantages in cognitive structure, problem solving strategies, and memory because the researcher who selected the problem has already narrowed the decision space down to only a few options. By contrast, the reason that laypeople think of experts as general problem solvers is that real experts are frequently called upon to sift through an

enormous number of possibilities in order to isolate the handful that are worthy of further investigation. To use a medical analogy, once the options have been narrowed down to only flu or pneumonia, almost anyone could be taught to diagnose which is more likely. However, real doctors are instead presented with a patient who has a wet cough, fever, and feels weak. The number of pathogens that produce such symptoms is probably in the hundreds. Most will resolve without incident, but bacterial pneumonia can kill within 24 hours. Decision scientists can claim that there is no advantage to expertise, but given the symptoms above, one will seek out an experienced infectious disease doc – and when the cards are on the table, so will they.

social influence

Vladas Griskevicius and Robert B. Cialdini

Social influence involves the changing of a person's attitude or behavior through the doings of another person. Here we focus on the realm of consumer behavior and on the factors that cause one individual to comply with another's request. The starting point in ascertaining what are the most successful influence strategies was an investigation of the techniques that are most successful in professions dependent on their ability to induce compliance (e.g., salespeople, fund-raisers, advertisers, political lobbyists, cult recruiters, negotiators, and con artists). What emerged from this period of systematic observation was a list of six principles on which compliance professionals appeared to base most of their influence attempts: (i) *reciprocity* – repaying a gift, favor, or service; (ii) *consistency* – acting consistently with prior commitments; (iii) *social validation* – following the lead of similar others; (iv) *liking* – accommodating the requests of those we know and like; (v) *authority* – conforming to the directives of legitimate authorities; and (vi) *scarcity* – seizing opportunities that are scarce or dwindling in availability. A full account of the origins, workings, prevalence, and scientific evidence of these six principles is available elsewhere (Cialdini, 2009; Cialdini and Goldstein, 2004; see also Goldstein, Martin, and Cialdini, 2008). Here we provide a summary of the principles and the scientific evidence regarding how each principle functions to influence consumer behavior.

RECIPROCITY

Pay every debt as if God wrote the bill.
(Ralph Waldo Emerson)

One of the most powerful norms in all human cultures is that for reciprocity, which obligates individuals to return the form of behavior that they have received from another. For instance, we report liking those who report liking us; we cooperate with cooperators and compete against competitors; we self-disclose to those who have self-disclosed to us; we yield to the persuasive

appeals of those who have previously yielded to one of our persuasive appeals; we try to harm those who have tried to harm us; and in negotiations, we make concessions to those who have offered concessions to us.

A *reciprocation rule* for compliance can be worded as follows: *One should be more willing to comply with a request from someone who has previously provided a favor or concession.* Under this general rule, people will feel obligated to provide gifts, favors, services, and aid to those who have given them such things first, sometimes even returning larger favors than those they have received. For example, restaurant servers who give two candies to guests along with the check increase their tips by 14.1%. A number of sales and fund-raising tactics also use this factor to advantage: the compliance professional initially gives something to the target person (e.g., a free sample), thereby causing the target to be more likely to give something in return. Often, this “something in return” is the target person's compliance with a substantial request.

The unsolicited gift, accompanied by a request for a donation, is a commonly used technique that employs the norm for reciprocity. One example is organizations sending free gifts through the mail. Including an unsolicited gift such as an individualized address labels can nearly double response rates. People often feel obligated to reciprocate even the smallest of gifts. For example, one study showed that people were more than twice as likely to fill out a lengthy survey when the request asking to complete the survey was accompanied by a handwritten Post-It note. Although such a note does not constitute a sizable gift, participants in the study recognized the extra effort and personal touch that this gesture required, and they felt obligated to reciprocate by agreeing to the request. Indeed, those who filled out the survey when it came with a handwritten sticky note returned it more promptly and gave more detailed answers.

A crucial aspect of successful reciprocity-based influence techniques involves activating the sense of obligation. The creation of obligation necessitates that the individual who desires to influence another needs to be the first to provide a gift or favor. It is noteworthy that this important aspect of reciprocity-based influence

techniques is often misemployed. For example, numerous commercial organizations offer donations to charity in return for the purchase of products or services – a general strategy falling under the rubric of “cause-related marketing.” Yet such tit-for-tat appeals often fail to engage reciprocity properly because influence agents do not provide benefits first and then allow recipients to return the favor. The suboptimal nature of such messages can be clearly seen in the results of an experiment in hotels, in which messages that urged guests to reuse their towels were varied systematically. Messages that promised a donation to an environmental cause if guests first reused their towels were no more effective than standard pro-environmental messages. Consistent with the obligating force of reciprocity, however, a message informing guests that the hotel had already donated increased towel reuse by 26%.

Reciprocal concessions. A variation of the norm for reciprocation of favors is that for reciprocation of concessions (also called the *door-in-the-face technique*). A requester uses this procedure by beginning with an extreme request that is nearly always rejected and then retreating to a more moderate favor – the one the requester had in mind from the outset. In doing so, the requester hopes that the retreat from extreme to moderate request will spur the target person to make a reciprocal concession by moving from initial rejection of the larger favor to acceptance of the smaller one. This reciprocal concessions strategy has been successfully used in fund-raising contexts where, after refusing a larger request for donations, people become substantially more likely than before to give the average contribution. This technique has also been used effectively to solicit blood donors, whereby potential donors were first asked about participating in long-term donor program. When that request was refused, the solicitor made a smaller request for a one-time donation. This pattern of a large request (that is refused) followed by a smaller request significantly increased compliance with the smaller request, as compared to a control condition of people who were asked only to perform the smaller one-time favor (50 vs 32% compliance rate).

Related to the door-in-the-face technique is the *that's-not-all technique*, which is frequently used by sales operators. An important procedural difference between the two techniques is that, in the that's-not-all tactic, the target person does not turn down the first offer before a better second offer is provided. After making the first offer but before the target can respond, the requester better the deal with an additional item or a price reduction. This approach has been found to be useful in selling more goods during a bake sale. One reason that this technique works appears to be the target person's desire to reciprocate for the better deal.

SOCIAL VALIDATION

*If you can keep your head when people all around
you are losing theirs, you probably haven't grasped
the situation*
(Jean Kerr)

People frequently decide on appropriate behaviors for themselves in a given situation by searching for information as to how similar others have behaved or are behaving. This simple principle of behavior accounts for an amazingly varied array of human responses. For instance, research has shown that New Yorkers use it in deciding whether to return a lost wallet, hotel guests use it when deciding whether to reuse their towels, children with a fear of dogs use it in deciding whether to risk approaching a dog, amusement park visitors use it to decide whether to litter in a public place, audience members use it in deciding whether a joke is funny, National Park visitors use it when deciding whether to commit theft, pedestrians use it in deciding whether to stop and stare at an empty spot in the sky, and, on the alarming side, troubled individuals use it in deciding whether to commit suicide.

The *social validation rule* for compliance can be stated as follows: *One should be more willing to comply with a request for behavior if it is consistent with what similar others are thinking or doing.* Our tendency to assume that an action is more correct if others are doing it is exploited in a variety of settings. Bartenders often “salt” their tip jars with a few dollar bills at the beginning of the evening to simulate

tips left by prior customers and, thereby, to give the impression that tipping with folded money is proper barroom behavior. Church ushers sometimes prime collection baskets for the same reason and with the same positive effect on proceeds. Advertisers love to inform us when a product is the “fastest growing” or “largest selling” because they do not have to convince us directly that the product is good; they need only say that many others think so, which seems proof enough. The producers of charity telethons devote inordinate amounts of time to the incessant listing of viewers who have already pledged contributions. The message being communicated to the holdouts is clear: “Look at all the people who have decided to give; it *must* be the correct thing to do.”

Social validation techniques are most likely to be effective in situations that are objectively unclear, and when there are indications of multiple similar others engaging in the particular behavior. For example, research shows that people are strongly influenced by the behavior of others when deciding whether to conserve energy in their homes. However, the influence of others' conservation behaviors increased as those others become more similar to the actual home resident: whereas other citizens of the state have an effect on conservation, behavior was more strongly influenced by the residents of the same city, and even more strongly influenced by the residents of their own neighborhood. Thus, when people are unsure, they are most likely to look to and accept the beliefs and behaviors of similar others as valid indicators of what they should believe and do themselves.

One tactic that compliance professionals use to engage the principle of social validation is called the *list technique*. This technique involves asking for a request only after the target person has been shown a list of similar others who have already complied. Studies show that when people are asked to donate money to charitable cause, those individuals who were initially shown a list of similar others who had already complied were significantly more likely to comply themselves. What's more, the longer the list, the greater was the effect.

CONSISTENCY

It is easier to resist at the beginning than at the end
(Leonardo Da Vinci)

Psychologists have long understood the strength of the consistency principle to direct human action. If we grant that the power of consistency is formidable in directing human action, an important practical question immediately arises: How is that force engaged? Psychologists think they know the answer – commitment. If a person can get you to make a commitment (that is, to take a stand, to go on record), that person will have set the stage for your consistency with that earlier commitment. Once a stand is taken, there is a natural tendency to behave in ways that are stubbornly consistent with the stand.

A *consistency rule* for compliance can be worded as follows: *after committing oneself to a position, one should be more willing to comply with requests for behaviors that are consistent with that position.* Any of a variety of strategies may be used to generate the crucial instigating commitment. One such strategy is the *foot-in-the-door technique*. A solicitor using this procedure will first ask for a small favor that is virtually certain to be granted. The initial compliance is then followed by a request for a larger, *related* favor. It has been found repeatedly that people who have agreed to the initial small favor are more willing to do the larger one, seemingly to be consistent with the implication of the initial action. For instance, home owners who had agreed to accept and wear a small lapel pin promoting a local charity were, as a consequence, more likely to contribute money to that charity when canvassed during a subsequent donation drive.

The foot-in-the-door technique is successful because performance of the initially requested action causes individuals to see themselves as possessing certain traits. For example, after taking and wearing the charity pin, subjects begin to see themselves as favorable toward charitable causes. Later, when asked to perform the larger, related favor of contributing to that charity, subjects would be more willing to do so to be

consistent with the “charitable” trait they had assigned to themselves.

Other, more unsavory techniques induce a commitment to an item and then remove the inducements that generated the commitment. Remarkably, the commitment frequently remains. For example, the *bait and switch procedure* is used by some retailers who may advertise certain merchandise (e.g., a room of furniture) at a special low price. When the customer arrives to take advantage of the special, he or she finds the merchandise to be of low quality or sold out. However, because customers have by now made an active commitment to getting new furniture at that particular store, they are more willing to agree to examine and, consequently, to buy alternative merchandise there.

A similar strategy is often employed by car dealers in the *low-ball technique*, which proceeds by obtaining a commitment to an action and *then* increasing the costs of performing the action. The automobile salesperson who “throws the low ball” induces the customer to decide to buy a particular model car by offering a low price on the car or an inflated one on the customer’s trade-in. After the decision has been made (and, at times, after the commitment is enhanced by allowing the customer to arrange financing, take the car home overnight, etc.), something happens to remove the reason the customer decided to buy. Perhaps a price calculation error is found, or the used car assessor disallows the inflated trade-in figure. By this time, though, many customers have experienced an internal commitment to that specific automobile and proceed with the purchase.

Another approach to employing the consistency principle also has gained popularity among commercial compliance professionals. Rather than inducing a new commitment to their product or service, many practitioners point out existing commitments within potential customers that are consistent with the product or service being offered – a tactic called the *labeling technique*. In this way, desirable existing commitments are made more visible to the customer, and the strain for consistency is allowed to direct behavior accordingly. For example, insurance agents are frequently taught to stress to new home owners that the purchase

of an expensive house reflects an enormous personal commitment to one’s home and the well-being of one’s family. Consequently, they argue it would only be consistent with such a commitment to home and family to purchase home and life insurance in amounts that befit the size of this commitment. Research of various kinds indicates that this sort of sensitization to commitments and to consequent inconsistencies can be effective in producing belief, attitude, and behavior change.

A more manipulative tactic than merely focusing people on their existing values is to put them in a situation where to refuse a specific request would be inconsistent with a value that people wish to be known as possessing. One such tactic is the *legitimization-of-paltry favors* (or even-a-penny-would-help) *technique*. Most people prefer to behave in ways that are consistent with a view of themselves as helpful, charitable individuals. Consequently, a fund-raiser who makes a request that legitimizes a paltry amount of aid (“could you give a contribution, even a penny would help”) makes it difficult for a target to refuse to give at all; by doing so he/she risks appearing to be a very unhelpful person. Notice that this procedure does not specifically request a trivial sum; that would probably lead to a profusion of pennies and a small total take. Instead, the request simply makes a minuscule form of aid acceptable, thereby reducing the target’s ability to give nothing and still remain consistent with the desirable image of a helpful individual. After all, how could a person remain committed to a helpful image after refusing to contribute when “even a penny would help”?

LIKING

The main work of a trial attorney is to make the jury like his client

(Clarence Darrow)

A fact of social interaction that each of us can attest to is that people are more favorably inclined toward the needs of those they know and like. Consequently, a *liking rule* for compliance can be worded as follows: *One should be more willing to comply with the requests of liked*

individuals. Could there be any doubt that this is the case after examining the remarkable success of the Tupperware Corporation and their “home party” demonstration concept? The demonstration party for Tupperware products is hosted by an individual, usually a woman, who invites to her home an array of friends, neighbors, and relatives, all of whom know that their hostess receives a percentage of the profits from every piece sold by the Tupperware representative, who is also there. In this way, the Tupperware Corporation arranges for its customers to buy from and for a friend rather than from an unknown salesperson. So favorable has been the effect on proceeds (\$3 million in sales per day) that the Tupperware Corporation has wholly abandoned its early retail outlets, and a Tupperware party begins somewhere every 2.7 seconds. Indeed, the success of this strategy has inspired many companies to use parties to sell their products, including cosmetics, arts-and-crafts, and even video games. Most influence agents, however, attempt to engage the liking principle in a different way: before asking a request, they get their targets to like *them*. But how do they do it? It turns out that the tactics that practitioners use to generate liking cluster around certain factors that have been shown by controlled research to increase liking.

Physical Attractiveness. Although it is generally acknowledged that good-looking people have an advantage in social interaction, research findings indicate that we may have sorely underestimated the size and reach of that advantage. There appears to be a positive reaction to good physical appearance that generalizes to such favorable trait perceptions as a talent, kindness, honesty, and intelligence. As a consequence, attractive individuals are more persuasive in terms of both changing attitudes and getting what they request. For instance, a study of Canadian Federal elections found that attractive candidates received more than two-and-a-half times the votes of unattractive ones. Equally impressive results seem to pertain to the judicial system. In a Pennsylvania study, for example, researchers rated the physical attractiveness of 74 separate male defendants at the start of their criminal trials. When, much later, the researchers checked the results of these cases via

court records, they found that the better-looking men received significantly lighter sentences. In fact, the attractive defendants were twice as likely to avoid incarceration as the unattractive defendants. When viewed in the light of such powerful effects, it is not surprising that extremely attractive models are employed to promote products and services, that sales trainers frequently include appearance and grooming tips in their lessons, or that, commonly, con men are handsome and con women pretty.

Similarity. We like people who are similar to us. This fact seems to hold true whether the similarity occurs in the area of opinions, personality traits, background, or lifestyle. Not only has research demonstrated that even trivial similarities can increase liking and have profound effects on important decisions such as careers and marriage partners but also perceived attitude similarity between oneself and a stranger can automatically activate thoughts of kinship, inducing a person to behave prosocially toward that similar other. Consequently, those who wish to be liked in order to increase our compliance can accomplish that purpose by appearing similar to us in any of a wide variety of ways. For that reason, it would be wise to be careful around salespeople who just *seem* to be just like us. Many sales training programs urge trainees to “mirror and match” the customer’s body posture, mood, and verbal style, as similarities along each of these dimensions have been shown to lead to positive results. Similarity in dress provides still another example. Several studies have demonstrated that we are more likely to help those who dress like us. In one study, done in the early 1970s when young people tended to dress either in “hippie” or “straight” fashion, experimenters donned hippie or straight attire and asked college students on campus for a dime to make a phone call. When the experimenter was dressed in the same way as the student, the request was granted in over two-thirds of the instances; but when the student and requester were dissimilarly dressed, a dime was provided less than half of the time. Another experiment shows how automatic our positive response to similar others can be. Marchers in a political demonstration were found not only to be more likely to sign the petition of a similarly dressed

requester but also to do so without bothering to read it first.

Compliments. Praise and other forms of positive estimation also stimulate liking. Actor Maclain Stevenson once described how his wife tricked him into marriage: “She said she liked me.” Although designed for a laugh, the remark is as much instructive as it is humorous. The simple information that someone fancies us can be a bewitchingly effective device for producing return liking and willing compliance. Although there are limits to our gullibility – especially when we can be sure that the flatterer’s intent is manipulative – as a rule we tend to believe praise and to like those who provide it. Evidence for the power of praise on liking comes from a study in which men received personal comments from someone who needed a favor from them. Some of the men got only positive comments, some only negative comments, and some got a mixture of good and bad. There were three interesting findings. First, the evaluator who offered only praise was liked the best. Second, this was so even though the men fully realized that the flatterer stood to gain from their liking of him. Finally, unlike the other types of comments, pure praise did not have to be accurate to work. Compliments produced just as much liking for the flatterer when they were untrue as when they were true. It is for such reasons that salespeople are educated in the art of praise. A potential customer’s home, clothes, car, taste, and so on, are all frequent targets for compliments.

Cooperation. Cooperation is another factor that has been shown to enhance positive feelings and behavior. Those who cooperate toward the achievement of a common goal are more favorable and helpful to each other as a consequence. That is why compliance professionals often strive to be perceived as cooperating partners of a target person. Automobile sales managers frequently set themselves as “villains” so that the salesperson can “do battle” on the customer’s behalf. The cooperative, pulling together kind of relationship that is consequently produced between the salesperson and customer, naturally leads to a desirable form of liking that promotes sales.

SCARCITY

The way to love anything is to realize that it might be lost

(Gilbert Keith Chesterton)

Opportunities seem more valuable to us when they are less available. Interestingly, this is often true even when the opportunity holds little attraction for us on its own merits. Take, as evidence, the experience of Florida State University students who, like most undergraduates, rated themselves dissatisfied with the quality of their cafeteria’s food. Nine days later, they had changed their minds, rating that food as significantly better than they had before. It is instructive that no actual improvement in food service had occurred between the two ratings. Instead, earlier on the day of the second rating students had learned that, because of a fire, they could not eat at the cafeteria for two weeks.

A *scarcity rule* for compliance can be worded as follows: *One should try to secure those opportunities that are scarce or dwindling.* With scarcity operating powerfully on the worth assigned to things, it should not be surprising that compliance professionals have a variety of techniques designed to convert this power to compliance. Probably the most frequently used such technique is the “limited number” tactic in which the customer is informed that membership opportunities, products, or services exist in a limited supply that cannot be guaranteed to last for long.

Related to the limited number tactic is the “deadline” technique in which an official time limit is placed on the customer’s opportunity to get what is being offered. Newspaper ads abound with admonitions to the customer regarding the folly of delay: “Last three days.” “Limited time offer.” “One week only sale.” The purest form of a decision deadline – right now – occurs in a variant of the deadline technique in which customers are told that, unless they make an immediate purchase decision, they will have to buy the item at a higher price, or they will not be able to purchase it at all. This tactic is used in numerous compliance settings. For example, a large child photography company urges parents to buy as many poses and copies

as they can afford because “stocking limitations force us to burn the unsold pictures of your children within 24 hours.” A prospective health club member or automobile buyer might learn that the deal offered by the salesperson is good for that one time; should the customer leave the premises, the deal is off. One home vacuum cleaner sales company instructs its trainees to claim to prospects that “I have so many other people to see that I have the time to visit a family only once. It’s company policy that even if you decide later that you want this machine, I can’t come back and sell it to you.” For anyone who thinks about it carefully, this is nonsense: The company and its representatives are in the business of making sales, and any customer who called for another visit would be accommodated gladly. The real purpose of the can’t-come-back-again claim is to evoke the possibility of loss that is inherent in the scarcity rule for compliance.

The idea of potential loss plays a large role in human decision making. In fact, people are generally more motivated by the thought of losing something than by the thought of gaining something of equal value. For instance, home owners told about how much money they could lose from inadequate insulation are more likely to insulate their homes than those told about how much money they could save. Similar results have been obtained on college campuses where students experienced much stronger emotions when asked to imagine losses rather than gains in their romantic relationships or grade point averages.

One naturally occurring example of the consequences of increased scarcity can be seen in the outcome of a decision by county officials in Miami to ban the use and possession of phosphate detergents. Spurred by the tendency to want what they could no longer have, the majority of Miami consumers came to see phosphate cleaners as better products than before. Compared to Tampa residents, who were not affected by the Miami ordinance, the citizens of Miami rated phosphate detergents as gentler, more effective in cold water, better whiteners and fresheners, and more powerful on stains. After passage of the law, they had even come to believe that phosphate detergents poured easier than did the Tampa consumers.

Other research has suggested that in addition to commodities, limited access to information makes the information more desirable and more influential. For example, wholesale beef buyers who were told of an impending imported beef shortage purchased significantly more beef when they were informed that the shortage information came from certain “exclusive” contacts that the importer had. Apparently, the fact that the scarcity news was itself scarce made it more valued and persuasive.

AUTHORITY

Follow an expert
(Virgil)

Legitimately constituted authorities are extremely influential persons. Whether they have acquired their positions through knowledge, talent, or fortune, their positions bespeak of superior information and power. For most people, conforming to the dictates of authority figures produces genuine practical advantages. Consequently, it makes great sense to comply with the wishes of properly constituted authorities. It makes so much sense, in fact, that people often do so when it makes no sense at all.

Take, for example, the strange case of the “rectal earache” reported by two professors of pharmacy. A physician ordered eardrops to be administered to the right ear of a patient suffering pain and infection there. But instead of writing out the location “right ear” on the prescription completely, the doctor abbreviated it so that the instructions read “place in R ear.” Upon receiving the prescription, the duty nurse promptly put the required number of eardrops into the patient’s anus. Obviously, rectal treatment of an earache made no sense. Yet, neither the patient nor the nurse questioned it.

An *authority rule* for compliance can be worded as follows: *One should be more willing to follow the suggestions of someone who is a legitimate authority.* Authorities may be seen as falling into two categories: authorities with regard to the specific situation and more general authorities. Compliance practitioners employ techniques that seek to benefit from the power

invested in authority figures of both types. In the case of authority relevant to a specific situation, we can note how often advertisers inform their audiences of the level of expertise of product manufacturers (e.g., “Fashionable men’s clothiers since 1841”; “Babies are our business, our only business”). At times, the expertise associated with a product has been more symbolic than substantive, for instance, when actors in television commercials wear physicians’ white coats to recommend a product. In one famous coffee commercial, the actor involved, Robert Young, did not need a white coat, as his prior identity as TV doctor Marcus Welby, MD, provided the medical connection. It is instructive that the mere symbols of a physician’s expertise and authority are enough to trip the mechanism that governs authority influence. One of the most prominent of these symbols, the bare title “Dr.,” has been shown to be devastatingly effective as a compliance device among trained hospital personnel. In what may be the most frightening study we know, a group of physicians and nurses conducted an experiment that documented the dangerous degree of blind obedience that hospital nurses accorded to an individual whom they had never met, but who claimed in a phone call to be a doctor. Ninety-five percent of those nurses were willing to administer an unsafe level of a drug merely because that caller requested it.

In the case of influence that generalizes outside of relevant expertise, the impact of authority (real and symbolic) appears equally impressive. For instance, researchers have found that, when wearing a security guard’s uniform, a requester could produce more compliance with requests (e.g., to pick up a paper bag in the street, to stand on the other side of a Bus Stop sign) that were irrelevant to a security guard’s domain of authority. Less blatant in its connotation than a uniform, but nonetheless effective, is

another kind of attire that has traditionally bespoken of authority status in our culture – the well-tailored business suit. One study found that three-and-a-half times as many people were willing to follow a jaywalker into traffic when he wore a suit and tie versus a work shirt and trousers.

SUMMARY

An important question for anyone interested in understanding resisting or harnessing the process of influence is, “which are the most powerful principles that motivate us to comply with another’s request?” We suggested that one way to assess such power would be to examine the practices of commercial compliance professionals for their pervasiveness. In other words, if compliance practitioners made widespread use of certain principles, this would be evidence for the natural power of these principles to affect everyday compliance in the realm of consumer behavior. Six principles emerged as the most popular in the repertoires of the most effective compliance pros: reciprocity, social validation, consistency, liking, scarcity, and authority. Close examination of the principles revealed broad professional usage that could be validated and explained by scientific research, indicating that these six principles engage central features of the human condition in the process of motivating compliance.

choice models

Seethu Seetharaman

A brand manager is interested in understanding market demand for his product and how marketing activities influence such demand. Since market demand is simply an aggregation of individual brand choices, numerically quantifying households' brand-choices and their dependence on marketing variables is of central importance to brand managers. Also called *discrete choice models*, brand choice models confront the problem of a household's choice of one brand from a set of mutually exclusive and collectively exhaustive brands within a product category. The model explains households' (observed) brand choices using both *observed* predictor variables (such as brands' prices, advertising activities etc.) and *unobserved* parameters (such as households' brand preferences, price sensitivities etc.), the latter being estimated using consumer choice data.

Consider the example of a household, having decided to buy a bottle of ketchup on a shopping visit, deciding on whether to buy *Heinz* or *Hunts*. The household first evaluates information about the attributes of each brand, for example quality, price, feature advertising (i.e., whether or not a brand is advertised in the newspaper that week) and end-of-aisle display (i.e., whether or not a brand is on display using a shelf talker). If one brand dominates the other along all four attributes, the household chooses the dominant brand. If it dominates the other in some attributes (e.g., price, display), but is dominated by the other brand in other attributes, (e.g., feature advertising, quality) the household's relative preferences for attributes determines which of the two brands the household will buy. A mathematical representation of how a household resolves these trade-offs between attributes in order to choose a brand is called a *brand choice model*. The household is assumed to first express the composite attractiveness of each brand (along the four attributes) using a scalar measure called *utility*. The household is then assumed to choose the brand that offers the higher utility. Since the household's utilities for brands are unknown to the marketing researcher, they must be treated as random variables. For this reason, brand choice

models are also called *random utility models*. Next we describe two such random utility models – Logit and Probit.

LOGIT MODEL

We will start with a discussion of the simplest logit model, the binary logit model, and then move on to the multinomial logit model.

Binary logit – a utility theoretic exposition. Let us consider the example of the household choosing between *Heinz* and *Hunts* brands of ketchup at a shopping occasion. Suppose the household's utilities for the two brands at time t are given by U_{1t} and U_{2t} respectively. The household will choose *Heinz* at time t if $U_{1t} > U_{2t}$ and *Hunts* if $U_{2t} > U_{1t}$. While U_{1t} and U_{2t} are known to the household, they are unknown to the marketing researcher. The marketing researcher specifies these utilities as follows.

$$\begin{aligned} U_{1t} &= V_{1t} + \varepsilon_{1t} \\ U_{2t} &= V_{2t} + \varepsilon_{2t} \end{aligned} \quad (1)$$

where V_{1t} and V_{2t} are the deterministic components of the utilities at time t , while ε_{1t} and ε_{2t} are the random components of the utilities (that represent the effects of unobserved variables, which are known to the household but unknown to the researcher, that influence households' utilities for brands).¹ The household's probability of choosing each brand is then expressed as follows.

$$\begin{aligned} \Pr(1) &= \Pr(U_{1t} > U_{2t}) \\ &= \Pr(V_{1t} + \varepsilon_{1t} > V_{2t} + \varepsilon_{2t}) \\ &= \Pr(\varepsilon_{2t} - \varepsilon_{1t} < V_{1t} - V_{2t}) \\ \Pr(2) &= \Pr(U_{2t} > U_{1t}) \\ &= \Pr(V_{2t} + \varepsilon_{2t} > V_{1t} + \varepsilon_{1t}) \\ &= \Pr(\varepsilon_{2t} - \varepsilon_{1t} > V_{1t} - V_{2t}) \end{aligned} \quad (2)$$

The deterministic components of the utilities are specified in terms of observed brand attributes as shown below.

$$\begin{aligned} V_{1t} &= V(X_{1t}) = \alpha_1 + X_{1t}\beta \\ V_{2t} &= V(X_{2t}) = \alpha_2 + X_{2t}\beta \end{aligned} \quad (3)$$

2 choice models

where $X_{1t} = (P_{1t}D_{1t}F_{1t})$ and $X_{2t} = (P_{2t}D_{2t}F_{2t})$ are brand-specific attribute vectors at time t , where P_{it} , D_{it} and F_{it} stand for price, display and feature of brand i respectively, $\beta = (\beta_1\beta_2\beta_3)'$, is a parameter-vector associated with these attributes,² and $\alpha = (\alpha_1\alpha_2)'$ is a vector of brand constants. The random components ε_{1t} and ε_{2t} are assumed to be distributed *iid* Gumbel with location parameter η and scale parameter $\mu > 0$. That is,

$$\begin{aligned} F(\varepsilon_{1t}) &= e^{-e^{-\mu(\varepsilon_{1t}-\eta)}} \\ F(\varepsilon_{2t}) &= e^{-e^{-\mu(\varepsilon_{2t}-\eta)}} \end{aligned} \quad (4)$$

This implies that $\varepsilon_{2t} - \varepsilon_{1t}$ is distributed logistic with location parameter 0 and scale parameter $\mu > 0$. That is,

$$F(\varepsilon_{2t} - \varepsilon_{1t}) = \frac{1}{1 + e^{-\mu(\varepsilon_{2t} - \varepsilon_{1t})}} \quad (5)$$

Using 5 in 2 we get

$$\begin{aligned} \Pr(1) &= \frac{1}{1 + e^{-\mu(V_{1t} - V_{2t})}} \\ \Pr(2) &= \frac{e^{-\mu(V_{1t} - V_{2t})}}{1 + e^{-\mu(V_{1t} - V_{2t})}} \end{aligned} \quad (6)$$

which can be rewritten as

$$\begin{aligned} \Pr(1) &= \frac{e^{\mu V_{1t}}}{e^{\mu V_{1t}} + e^{\mu V_{2t}}} \\ \Pr(2) &= \frac{e^{\mu V_{2t}}}{e^{\mu V_{1t}} + e^{\mu V_{2t}}} \end{aligned} \quad (7)$$

Substituting 3 in 7 yields

$$\begin{aligned} \Pr(1) &= \frac{e^{\mu(\alpha_1 + X_{1t}\beta)}}{e^{\mu(\alpha_1 + X_{1t}\beta)} + e^{\mu(\alpha_2 + X_{2t}\beta)}} \\ \Pr(2) &= \frac{e^{\mu(\alpha_2 + X_{2t}\beta)}}{e^{\mu(\alpha_1 + X_{1t}\beta)} + e^{\mu(\alpha_2 + X_{2t}\beta)}} \end{aligned} \quad (8)$$

Equation 8 represents the *binary logit model*. Since the parameter μ is confounded with the scale of the β 's, it is usually fixed at 1. This yields the following standard version of the binary logit model.

$$\begin{aligned} \Pr(1) &= \frac{e^{\alpha_1 + X_{1t}\beta}}{e^{\alpha_1 + X_{1t}\beta} + e^{\alpha_2 + X_{2t}\beta}} \\ \Pr(2) &= \frac{e^{\alpha_2 + X_{2t}\beta}}{e^{\alpha_1 + X_{1t}\beta} + e^{\alpha_2 + X_{2t}\beta}} \end{aligned} \quad (9)$$

The brand choice probabilities in 9 will remain unchanged if a constant is added to all brands' utilities. For this reason, the intercept term associated with one of the brands is fixed (usually at zero). This yields the following *estimable* version of the binary logit model.

$$\begin{aligned} \Pr(1) &= \frac{e^{\alpha_1 + X_{1t}\beta}}{e^{\alpha_1 + X_{1t}\beta} + e^{X_{2t}\beta}} \\ \Pr(2) &= \frac{e^{X_{2t}\beta}}{e^{\alpha_1 + X_{1t}\beta} + e^{X_{2t}\beta}} \end{aligned} \quad (10)$$

The idea of random utility goes way back to Thurstone (1927). However, a formal exposition of the logit model from random utility primitives, as laid down in this section, first appeared in McFadden (1974).

Binary logit – a regression-based exposition. The binary logit model can also be understood as a regression model, where the dependent variable y_t takes one of two values, that is, 1 or 0. The regression model looks as shown below.

$$Y_t = \pi(X_t) + \varepsilon$$

where

$$\pi(X_t) = \frac{e^{\alpha_1 + X_{1t}\beta}}{e^{\alpha_1 + X_{1t}\beta} + e^{X_{2t}\beta}}$$

and

$$\begin{aligned} \varepsilon_{1t} &= 1 - \pi(X_t) \text{ if } Y_t = 1 \\ &= -\pi(X_t) \text{ if } Y_t = 0 \end{aligned} \quad (11)$$

This regression-based representation of a binary logit model is also called a *logistic regression*. There are two key differences between the conventional linear regression model and the logistic regression model: one, unlike the linear regression model where $E(Y_t|X_t) = X_t\beta$ which is *linear* in X_t and *unbounded*, in the logistic regression model $E(Y_t|X_t) = \pi(X_t)$, which is *S-shaped* in X_t and *bounded* between 0 and 1; two, unlike the linear regression model where ε has a *normal* distribution with mean 0 and *constant* variance σ^2 , in the logistic regression model ε has a *two-point discrete* distribution with mean 0 and *heteroscedastic* variance $\pi(X_t)[1 - \pi(X_t)]$. Since the observed choice outcome Y_t has a

binomial distribution with parameter $\pi(X_t)$, that is a *logit* function of the marketing variables, this model is also called the *binomial logit* model. Next we will discuss how to estimate the parameters of the binary logit/binomial logit/logistic regression model using consumer choice data.

Maximum likelihood estimation of the binary logit model. Given n independent observations of (X_t, Y_t) the parameters of the logistic regression model are estimated by maximizing the following *likelihood* function.

$$l(\beta) = \prod_{t=1}^n \pi(X_t)^{Y_t} [1 - \pi(X_t)]^{1-Y_t} \quad (12)$$

which is equivalent to maximizing the following *log-likelihood* function.

$$L(\beta) = \ln[l(\beta)] = \sum_{t=1}^n \{Y_t \ln \pi(X_t) + (1 - Y_t) \ln [1 - \pi(X_t)]\} \quad (13)$$

Maximization involves differentiating $L(\beta)$ with respect to β and setting the resulting expressions to zero. This yields the following $(p + 1)$ *likelihood equations*.

$$\begin{aligned} \sum_{t=1}^n [Y_t - \pi(X_t)] &= 0 \\ \sum_{t=1}^n X_{tk} [Y_t - \pi(X_t)] &= 0 \quad (k = 1, \dots, p) \end{aligned} \quad (14)$$

where $p = 3$ stands for the number of predictor variables in the model. Since the likelihood equations are *non-linear* in β , they require special numerical methods for their solution (unlike the linear regression model where the first-order equations are *linear* in β). Optimization modules in programming languages such as SAS, Gauss, Fortran, and so on, automatically employ these numerical methods. One such numerical method is the *Newton-Raphson* method that iterates using the formula

$$\hat{\beta}_{i+1} = \hat{\beta}_i - \left[\frac{\partial^2 L}{\partial \beta \partial \beta'} \right]_{\hat{\beta}_i}^{-1} \left[\frac{\partial L}{\partial \beta} \right]_{\hat{\beta}_i} \quad (15)$$

and converges when $|\hat{\beta}_{i+1} - \hat{\beta}_i|$ is within a predetermined tolerance level ξ . Faster methods, such as the *Davidson Fletcher Powell* (DFP) method, use approximations for the derivatives instead of directly evaluating the derivatives. Solving the likelihood equations using one of these numerical methods yields $\hat{\beta}$ and $\hat{\pi}(X_t)$, the maximum likelihood estimates (MLE) of β and $\pi(X_t)$ respectively. Before MLE became computationally easy to perform, marketing researchers employed an alternative estimation procedure to estimate the parameters of the logit model. This was based on the *logit transformation*

$$\ln \left[\frac{\pi(X_t)}{1 - \pi(X_t)} \right] = \alpha_1 + (X_{1t} - X_{2t})\beta \quad (16)$$

which suggested that one could run a linear regression of $\ln \left[\frac{\pi(X_t)}{1 - \pi(X_t)} \right]$ versus $X_{1t} - X_{2t}$ in order to estimate $\hat{\beta}$. In order to do this, researchers would group observations with the same $X_{1t} - X_{2t}$ together, compute the fraction of purchase observations in each group to estimate $\hat{\pi}(X_t)$, and then run a linear regression of $\ln \left[\frac{\hat{\pi}(X_t)}{1 - \hat{\pi}(X_t)} \right]$ versus $X_{1t} - X_{2t}$ across groups. For an illustration of this estimation procedure, see Jones and Zufryden (1982). In this approach, heteroscedasticity in the errors must be explicitly adjusted for. This method is now out of vogue since current statistical software packages have MLE routines built into them. Further, MLEs have desirable asymptotic properties, as discussed next.

Asymptotic properties of maximum likelihood estimators. MLEs have desirable asymptotic properties, that is, properties that can be invoked in extremely large samples (such as those available from scanner panel data) and easily derivable compared to small-sample properties. Two of these properties are described below.

1. *Consistency.* This refers to the distribution of the MLE “collapsing” on the true parameter value as the sample gets larger. It implies

4 choice models

the following.

$$\begin{aligned}
 & \lim_{n \rightarrow \infty} \Pr[\beta - \varepsilon < \hat{\beta} < \beta + \varepsilon] \\
 &= 1 \quad \forall \varepsilon > 0 \\
 & \lim_{n \rightarrow \infty} E[(\hat{\beta} - \beta)^2] \\
 &= \lim_{n \rightarrow \infty} E[(\hat{\beta} - E\hat{\beta})^2] \\
 &+ [E\hat{\beta} - \beta]^2 = 0
 \end{aligned} \tag{17}$$

which can be rewritten as

$$\begin{aligned}
 & p \lim_{n \rightarrow \infty} \hat{\beta} = \beta \\
 & \lim_{n \rightarrow \infty} \text{MSE}(\hat{\beta}) = \lim_{n \rightarrow \infty} [\text{Var}(\hat{\beta}) \\
 &+ \text{Bias}(\hat{\beta})^2] = 0
 \end{aligned} \tag{18}$$

where $\text{MSE}(\hat{\beta})$, $\text{Var}(\hat{\beta})$ and $\text{Bias}(\hat{\beta})$ stand for the mean-squared-error, variance and bias associated with $\hat{\beta}$ respectively. Consistency, therefore, implies that

$$\lim_{n \rightarrow \infty} \text{Var}(\hat{\beta}) = 0, \lim_{n \rightarrow \infty} \text{Bias}(\hat{\beta})^2 = 0 \tag{19}$$

If $\hat{\beta}$ is a consistent estimator of β , then $h(\hat{\beta})$ is a consistent estimator of $h(\beta)$ where $h(\cdot)$ is a continuous function. This is called *Slutsky's theorem*.³ Further, if $\hat{\beta}$ is an MLE of β , then $h(\hat{\beta})$ is an MLE of $h(\beta)$ where $h(\cdot)$ is a continuous function. This greatly simplifies the algebraic derivation of the MLE of a highly non-linear function of model parameters.

2. *Best asymptotic normality (BAN)*. The distribution of the MLE can be well approximated by a normal distribution as the sample gets larger as shown below.

$$\lim_{n \rightarrow \infty} \sqrt{n}[\hat{\beta} - \beta] \sim N(0, \sigma^2) \tag{20}$$

where σ^2 is called the *asymptotic variance* of the MLE. Further, the MLE is *asymptotically efficient*, that is, σ^2 tends to zero (as $n \rightarrow \infty$) faster than the variance of any other consistent estimator.⁴ The asymptotic variance of $\hat{\beta}$ is equal to the *Cramer Rao Lower Bound* (i.e., the

minimum variance that an unbiased estimator can have), and is estimated as shown below.

$$\text{Var}(\hat{\beta}) = I^{-1}(\hat{\beta})$$

where

$$I(\hat{\beta}) = - \begin{bmatrix} \frac{\partial^2 L(\beta)}{\partial \beta_1^2} & \frac{\partial^2 L(\beta)}{\partial \beta_1 \partial \beta_2} & \cdots & \frac{\partial^2 L(\beta)}{\partial \beta_1 \partial \beta_p} \\ \cdots & \frac{\partial^2 L(\beta)}{\partial \beta_2^2} & \cdots & \frac{\partial^2 L(\beta)}{\partial \beta_2 \partial \beta_p} \\ \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \frac{\partial^2 L(\beta)}{\partial \beta_p^2} \end{bmatrix}_{\beta=\hat{\beta}} \tag{21}$$

where $I(\hat{\beta})$ is called the *information matrix*. The variance of β_k is simply the k th diagonal element of $\text{Var}(\hat{\beta})$. The information matrix can be written compactly as shown below.

$$\begin{aligned}
 \hat{I}(\hat{\beta}) &= X' V X \\
 V &= - \begin{bmatrix} \hat{\pi}_1 & 0 & \cdots & 0 \\ (1 - \hat{\pi}_1) & \hat{\pi}_2 & \cdots & 0 \\ \cdots & (1 - \hat{\pi}_2) & \cdots & \cdots \\ \cdots & \cdots & \cdots & \hat{\pi}_n \\ \cdots & \cdots & \cdots & (1 - \hat{\pi}_n) \end{bmatrix}
 \end{aligned} \tag{22}$$

where X is the $n^*(p+1)$ predictor matrix.

If $g(\hat{\beta})$ is a continuous function of $\hat{\beta}$, the asymptotic variance of $g(\hat{\beta})$ can be calculated as the square of the first derivative of $g(\beta)$ with respect to β (evaluated at $\hat{\beta}$) times the asymptotic variance of $\hat{\beta}$. This technique, based on approximating the function $g(\beta)$ as a linear function of β at $\beta = \hat{\beta}$, is called the *delta method*.

Interpreting logit parameters. In a linear regression, the coefficient β_k stands for the change in y for a unit change in X_k . In a logistic regression, β_k stands for the change in *log-odds* for a unit change in X_k , as shown below.

$$\hat{\beta}_k = \ln \left[\frac{\hat{\pi}(X_k + 1)}{1 - \hat{\pi}(X_k + 1)} \right] - \ln \left[\frac{\hat{\pi}(X_k)}{1 - \hat{\pi}(X_k)} \right] \tag{23}$$

which can also be written as

$$\hat{\beta}_k = \ln \left[\frac{\frac{\hat{\pi}(X_k+1)}{1-\hat{\pi}(X_k+1)}}{\frac{\hat{\pi}(X_k)}{1-\hat{\pi}(X_k)}} \right] = \ln[OR_k] \quad (24)$$

where OR_k stands for the *odds-ratio* based on variable X_k . In other words, the coefficient β_k stands for the *log-odds ratio* based on the variable X_k .

Hypothesis testing. The *likelihood ratio* (LR) test is used to test hypotheses about parameters of the binary logit model, for example, testing the joint significance of a set of estimates. It is based on the following test statistic.

$$G = -2^* \ln \left[\frac{l^*}{l} \right] = -2^*[L^* - L] \sim \chi_k^2 \quad (25)$$

where L^* is the log-likelihood of the restricted model, L is the log-likelihood of the unrestricted model, k is the number of restrictions. If one used this to test the significance of the estimated price coefficient, L^* will be the log-likelihood of the model estimated after dropping the price variable from the model, and $k = 1$. The LR test is analogous to the F-test in linear regression models.

The *Wald* test is used to test individual significance of estimated parameters. It is based on the following test statistic.

$$W = \frac{\hat{\beta}_k}{\text{SE}(\hat{\beta}_k)} \sim t_1 \quad (26)$$

where $\hat{\beta}_k$ is the MLE of the coefficient of the k th predictor variable and $\text{SE}(\hat{\beta}_k)$ is the estimate of its standard error. One can also construct confidence intervals for parameters using the *Wald* statistic. The *Wald* test is analogous to the t -test in linear regression models. The difference between the *Wald* test and the LR test is that the *Wald* test employs the estimates themselves while the LR test uses the log-likelihood values instead. The *Wald* test has lower computational cost since the LR test involves the estimation of two models – restricted and unrestricted. Asymptotically, the two tests are equivalent. In fact, there is another asymptotically equivalent test called the *score test* or *Lagrange multiplier test* that uses derivatives instead.

Assessing model fit. Model fit is typically assessed on the basis of the “distance” between observed Y ’s and fitted \hat{Y} ’s. Some of the popular measures of model fit are listed below.

1. *Pearson chi-square statistic.* This is given by

$$\sum_{c=1}^C r(Y_c, \hat{\pi}_c)^2 \sim \chi_{C-(p+1)}^2 \quad (27)$$

where

$$r(Y_c, \hat{\pi}_c) = \frac{Y_c - m_c \hat{\pi}_c}{\sqrt{m_c \hat{\pi}_c (1 - \hat{\pi}_c)}} \quad (28)$$

where Y_c stands for the number of observed positive responses with *covariate pattern* c . A *covariate pattern* refers to a single set of values for the covariates in a model, for example, price = \$1, display = 1, feature = 0. If C refers to the number of distinct values of covariates that are observed in the data ($C \leq n$), and m_c refers to the number of observations with covariate pattern c , then $\sum_{c=1}^C m_c = n$. If the model fits the data well, one would expect this statistic to be less than the critical value from the chi-square table.

2. *Hit rate.* Also called *classification rate*, refers to the percentage of observations that are correctly classified. It is given by

$$\frac{n - \sum_{t=1}^n |Y_t - \hat{Y}_t|}{n} \quad (29)$$

where Y_t is the observed choice outcome at time t and $\hat{Y}_t = 1$ if $\hat{Y}_t > 0.5$. A disadvantage of the *hit rate* measure is that it depends heavily on the distribution of the true probabilities in the sample. If the true probabilities are all close to 0 or 1, most models would do equally well on this criterion. Conversely, if the true probabilities are all close to 0.5, even a good model may not do well on this criterion.

3. *Efron’s (1978) R^2 .* This is given by

$$1 - \frac{\sum_{t=1}^n (Y_t - \hat{\pi}_t)^2}{\sum_{t=1}^n (Y_t - \bar{Y})^2} \quad (30)$$

6 choice models

This measure does not suffer from the deficiency of the *hit rate* measure, and is in the same spirit as the R^2 measure in the linear regression model. The numerator of the second term is called *sum of squared residuals*. The use of this measure cannot be defended strongly since the logit model is a heteroscedastic regression model.

4. *McFadden's (1974) Adjusted R^2* . This is given by

$$R_{adj}^2 = 1 - \frac{L_p}{L_o} \quad (31)$$

where L_p is the log-likelihood of the full model and L_o is the log-likelihood of a logit model with an intercept only.

5. *Log-likelihood*. The maximized value of the log-likelihood function itself is an intuitive measure of model fit. In order to adjust for the number of parameters in the model, one can use the L-R test to test whether the change in log-likelihood in going from a restricted version of the proposed model to the proposed model is statistically significant. The L-R test requires that the two models being compared are nested models.
6. *Akaike information criterion (AIC)*. This is used to compare non-nested models; the measure is given by

$$AIC = -2 * L + 2 * k \quad (32)$$

which adjusts the log-likelihood L based on the number of parameters k .

7. *Schwarz Bayesian criterion (SBC)*. This is also used to compare non-nested models, the measure is given by

$$SBC = -2 * L + \ln n * k \quad (33)$$

which penalizes a highly parameterized model more than the AIC if $n > e^2$.

External validation refers to the evaluation of the above-mentioned goodness-of-fit measures for a model using a *holdout sample* of observations. For example, if one used the first 80% of a household's purchase observations to fit model parameters ("calibration"), one can then evaluate hit rates, adjusted R^2 for the remaining 20% of

the household's purchase observations using the estimated model parameters ("holdout validation"). Horowitz and Louviere (1993) propose a holdout validation scheme that takes into account sampling errors in predicted choices. It is based on estimating the linear regression model $Y_i = \alpha \hat{\pi}_i + \varepsilon_{ji}$, and testing the hypothesis $\hat{\alpha} = 1$.

Multinomial logit – a utility theoretic exposition.

Let us consider the example of a household choosing between \mathcal{J} brands of laundry detergents – *Tide*, *Wisk*, *Surf*, *Cheer*, *Bold*, *Gain*, *Era*, *Oxydol*, *Dreft*, *Ivory Snow*, and so on, at a shopping occasion. Suppose the household's utilities for the \mathcal{J} brands at time t are given by U_{1t}, \dots, U_{jt} respectively. The household will choose *Cheer* (say, brand i) at time t if $U_{it} > U_{jt} \forall j \neq i$. The household's probability of choosing *Cheer* is then expressed as follows.

$$\Pr(i) = \Pr(U_{it} > U_{jt}, j \neq i) \quad (34)$$

which can be rewritten as

$$\Pr(i) = \Pr(U_{it} > \max_{j \neq i} U_{jt}) \quad (35)$$

which conveniently reduces the problem of making \mathcal{J} pair-wise utility comparisons to making just one pair-wise comparison, that is, between U_i and $\max_{j \neq i} U_{jt}$. If we know the distributions of the two random variables U_i and $\max_{j \neq i} U_{jt}$, the probability in 35 can be appropriately derived.

We assume the random components in the utilities, ε_{jt} , to be distributed *iid* Gumbel with location parameter η and scale parameter $\mu > 0$. This implies that $U_{jt} = V_{jt} + \varepsilon_{jt}$ is distributed Gumbel with location parameter $\eta + V_{jt}$ and scale parameter $\mu > 0$. The distribution of $\max_{j \neq i} U_{jt}$, is derived as follows:

$$\begin{aligned} F_{\max_{j \neq i} U_{jt}}(u) &= \prod_{j \neq i} F_{U_{jt}}(u) \\ &= \prod_{j \neq i} e^{-e^{-\mu(u - V_{jt} - \eta)}} = e^{-\sum_{j \neq i} e^{-\mu(u - V_{jt} - \eta)}} \\ &= e^{-e^{-\mu(u - \frac{1}{\mu} \ln \sum_{j \neq i} e^{\mu(V_{jt} + \eta)})}} \\ &= e^{-e^{-\mu(u - \frac{1}{\mu} \ln \sum_{j \neq i} e^{\mu(V_{jt} + \eta)})}} \end{aligned} \quad (36)$$

which is distributed Gumbel with location parameter $\frac{1}{\mu} \ln \sum_{j \neq i} e^{\mu(V_{jt} + \eta)}$ and scale parameter μ . Now we can rewrite 35 as follows

$$\Pr(i) = \Pr(\max_{j \neq i} U_{jt} - U_{it} < 0) \quad (37)$$

Since the difference between two Gumbel variates (with a common scale parameter μ) is distributed logistic whose location parameter is simply the difference between the location parameters of the two Gumbel variates, 37 can be written as follows

$$\begin{aligned} \Pr(i) &= F_{\text{logistic}}(0) \\ &= \frac{1}{1 + e^{-\mu \left(\eta + V_{it} - \frac{1}{\mu} \ln \sum_{j \neq i} e^{\mu(V_{jt} + \eta)} \right)}} \end{aligned} \quad (38)$$

which can be written in a more convenient form as follows (setting $\eta = 0$)

$$\Pr(i) = \frac{e^{\mu V_{it}}}{\sum_{j=1}^J e^{\mu V_{jt}}} \quad (39)$$

which represents the *multinomial logit model* (MNL). Since the parameter μ is confounded with the scale of the β 's, it is usually fixed at 1. This yields the following standard version of the MNL model.

$$\Pr(i) = \frac{e^{V_{it}}}{\sum_{j=1}^J e^{V_{jt}}} = \frac{e^{\alpha_{it} + X_{it}\beta}}{\sum_{j=1}^J e^{\alpha_{jt} + X_{jt}\beta}} \quad (40)$$

The brand choice probabilities in 40 will remain unchanged if a constant is added to all brands' utilities. For this reason, the intercept term associated with one of the brands is fixed (usually at zero). This yields the following *estimable* version of the MNL model (where the intercept of the J th brand has been fixed at zero).

$$\Pr(i) = \pi_i = \frac{e^{\alpha_{it} + X_{it}\beta}}{\sum_{j=1}^{J-1} e^{\alpha_{jt} + X_{jt}\beta} + e^{X_{Jt}\beta}} \quad (41)$$

For the first published application of the MNL model to scanner panel data on brand choices,

see Guadagni and Little (1983). It is useful to note here that the MNL model is equally derivable using *deterministic utility* (instead of *random utility*) primitives. For example, one could assume that households have deterministic utilities (V_j) for brands, but have probabilistic rules that determine which brands they buy (Luce, 1959). If the probabilistic rule is the *Luce Choice Axiom*, a household's brand choice probabilities are given by

$$\Pr(i) = \pi_i = \frac{V_i}{\sum_{j=1}^J V_j}, \quad (42)$$

which would be identical to the MNL model in 41 if $V_i = e^{\alpha_i + X_i\beta}$.

Maximum likelihood estimation of the MNL model. Given n independent observations of (X_t, Y_t) the parameters of the MNL model are estimated by maximizing the following *likelihood* function.

$$l(\beta) = \prod_{t=1}^n \pi_1(X_t)^{Y_{1t}} \pi_2(X_t)^{Y_{2t}} \dots \pi_J(X_t)^{Y_{Jt}} \quad (43)$$

which is equivalent to maximizing the following *log-likelihood* function.

$$\begin{aligned} L(\beta) = \ln[l(\beta)] &= \sum_{t=1}^n \{ Y_{1t} \ln \pi_1(X_t) \\ &+ Y_{2t} \ln \pi_2(X_t) + \dots + Y_{Jt} \ln \pi_J(X_t) \} \end{aligned} \quad (44)$$

Maximization involves differentiating $L(\beta)$ with respect to β and setting the resulting expressions to zero. This yields the following $(J-1)^*(p+1)$ *likelihood equations*.

$$\begin{aligned} \sum_{t=1}^n [Y_{jt} - \pi_j(X_t)] &= 0, j = 1, \dots, J-1 \\ \sum_{t=1}^n X_{jkt} [Y_{jt} - \pi_j(X_t)] &= 0 (k = 1, \dots, p), \\ j &= 1, \dots, J-1 \end{aligned} \quad (45)$$

Since these equations are *non-linear* in β , they require special methods for their solution. One

8 choice models

uses the *Cramer Rao Lower Bound* to estimate the variance-covariance matrix of the estimated parameters as shown below.

$$\text{Var}(\beta) = I^{-1}(\hat{\beta})$$

where

$$I(\hat{\beta}) = - \begin{bmatrix} \frac{\partial^2 L(\beta)}{\partial \beta_1^2} & \frac{\partial^2 L(\beta)}{\partial \beta_1 \partial \beta_2} & \cdots & \frac{\partial^2 L(\beta)}{\partial \beta_1 \partial \beta_p} \\ \cdots & \frac{\partial^2 L(\beta)}{\partial \beta_2^2} & \cdots & \frac{\partial^2 L(\beta)}{\partial \beta_2 \partial \beta_p} \\ \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \frac{\partial^2 L(\beta)}{\partial \beta_p^2} \end{bmatrix} \quad (46)$$

where $I(\hat{\beta})$ is called the *information matrix*. The variance of β_k is simply the k th diagonal element of $\text{Var}(\beta)$. The information matrix can be written compactly as shown below.

$$\hat{I}(\hat{\beta}) = - \begin{bmatrix} \hat{I}(\hat{\beta})_{11} & \hat{I}(\hat{\beta})_{12} & \cdots & \hat{I}(\hat{\beta})_{1j-1} \\ \cdots & \hat{I}(\hat{\beta})_{22} & \cdots & \hat{I}(\hat{\beta})_{2j-1} \\ \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \hat{I}(\hat{\beta})_{j-1j-1} \end{bmatrix}$$

$$\hat{I}(\hat{\beta})_{ij} = X' V_{ij} X$$

$$\hat{I}(\hat{\beta})_{jk} = X' V_{jk} X$$

$$V_{jj} = - \begin{bmatrix} \hat{\pi}_{1j} & 0 & \cdots & 0 \\ (1 - \hat{\pi}_{1j}) & & & \\ \cdots & \hat{\pi}_{2j} & \cdots & 0 \\ & (1 - \hat{\pi}_{2j}) & & \\ \cdots & \cdots & \cdots & \\ \cdots & \cdots & \cdots & \hat{\pi}_{nj-1} \\ & & & (1 - \hat{\pi}_{nj-1}) \end{bmatrix}$$

$$V_{ij} = - \begin{bmatrix} \hat{\pi}_{1j} \hat{\pi}_{1k} & 0 & \cdots & 0 \\ \cdots & \hat{\pi}_{2j} \hat{\pi}_{2k} & \cdots & 0 \\ \cdots & \cdots & \cdots & \\ \cdots & \cdots & \cdots & \hat{\pi}_{nj-1} \hat{\pi}_{nk-1} \end{bmatrix} \quad (47)$$

where X is the $n^*(p+1)$ predictor matrix.

Role of the scale parameter. The scale parameter μ of the logit model cannot be identified since it is confounded with the utility parameters β . Hence it is arbitrarily set to 1 when dealing with a given household's brand choices. Suppose we want to compare the estimated price sensitivity of two different households. The estimates are confounded with their respective scale factors. Scale factor differences (i.e., variance differences) between the two households must therefore be isolated before comparing utility parameter estimates across individuals. Otherwise, statistical tests such as the *Chow test* may lead one to falsely conclude that parameter vectors differ between households when indeed they do not. Swait and Louviere (1993) propose a way of testing equality in parameter estimates across datasets that works as follows: first, separate logit models are estimated for the two datasets, yielding maximized log-likelihood of L_1 and L_2 respectively; second, the data from the two datasets are pooled and a logit model is estimated based on the assumption of a common β , but different scale factors for the two datasets. This yields estimates of β and the ratio (μ_2/μ_1) along with the maximized log-likelihood L_μ . An LR test of L_μ versus $L_1 + L_2$ is a test of the hypothesis $H_1: \beta_1 = \beta_2 = \beta$. Therefore, even though one cannot identify the scale parameter for any given dataset, one can identify the ratio of the scale parameter for two different datasets.

Price elasticities. One useful managerial measure is the price elasticity of a brand, that is the percentage change in a brand's demand in response to a percentage change in its price. A brand's price elasticities are computed as follows

$$\text{OwnElas}_i = \frac{\partial \pi_{it}}{\partial P_{it}} * \frac{P_{it}}{\pi_{it}}$$

$$\text{CrossElas}_{ij} = \frac{\partial \pi_{it}}{\partial P_{jt}} * \frac{P_{jt}}{\pi_{it}} \quad (48)$$

where OwnElas_i and CrossElas_{ij} stand for the own- and cross-price elasticity (with respect to the price of brand j) of brand i , π_{it} and π_{jt} stand for the household's logit probabilities of buying brands i and j respectively at time t , P_{it} and P_{jt} stand for the prices of the i th and j th brands

respectively at time t . For a logit model it is easy to show that

$$\begin{aligned}\text{OwnElast}_i &= [1 - \pi_{ii}]P_{ii}\beta_k \\ \text{CrossElast}_{ij} &= -\pi_{ji}P_{ji}\beta_k\end{aligned}\quad (49)$$

which implies that (i) smaller brands have higher own- and cross-price elasticities than larger brands, and (ii) higher priced brands have larger own-price elasticities but smaller cross-price elasticities than lower-priced brands. These restrictions are an artifact of the logit model, and may not necessarily be appropriate for the data in hand.

The IIA property. In the MNL model, the ratio of a household's choice probabilities for any two brands is unaffected by the presence of other brands in the market. In other words,

$$\frac{P_{ii}}{P_{ji}} = \frac{e^{\alpha_{ii} + X_{ii}\beta}}{e^{\alpha_{ji} + X_{ji}\beta}} = e^{(\alpha_{ii} - \alpha_{ji}) + (X_{ii} - X_{ji})\beta} \quad (50)$$

which is independent of other brands $k \neq i, j$. This property, also called *independence from irrelevant alternatives* (IIA), is unnecessarily restrictive and leads to three types of problems.⁵ The first, also called the *similarity problem* (first noted by Debreu, 1960), can be understood as follows. Suppose a household chooses between two brands – *Coke* and *7-Up* – in a two-brand product market. When a new brand – *Pepsi* – is introduced to this market, the logit model would predict that the household's choice probability for the new brand will draw an equal proportion from the household's brand choice probabilities for *Coke* and *7-Up*. However, it is more reasonable to expect that *Pepsi* will draw disproportionately more from *Coke* than from *7-Up*, almost to the extent that the household's choice probability for *7-Up* will remain unchanged. The logit model cannot allow for this. The second problem, called the *dominance problem*, can be understood as follows: suppose a household has equal choice probabilities (i.e., 0.5) for *Coke* and *7-Up* when only these two brands are available in the product category, and equal choice probabilities (i.e., 0.5) for *Pepsi* and *7-Up* when only these two brands are available. Also suppose that *Pepsi* almost completely dominates *Coke* for the household when both are available, that is, when

Pepsi and *Coke* are the only available brands, the household's choice probabilities for the two brands are 0.95 and 0.05 respectively. Such a pattern of household choices, while perfectly reasonable, also cannot be represented using a logit model. The third problem, called the *regularity problem*, can be understood as follows: suppose a household has equal choice probabilities (i.e., 0.5) for *Coke* and *7-Up* when only these two brands are available in the product category. However, the household's choice probability for *7-Up* can increase after the introduction of *Pepsi* either because the household ends up switching between cola and non-cola in a desire for variety or because the household ends up valuating *7-Up* higher after the entry of *Pepsi* on account of *7-Up*'s uniqueness in the product category. The logit model cannot allow for such a probability increase for *7-Up*. To summarize, therefore, the IIA restriction of the logit model leads to at least three types of problems while modeling brand choice data. The IIA restriction is an artifact of the logit model's assumption that the random components of the household's brand utilities (i.e., the ε_j 's) are *iid*.

Whether or not the IIA restriction is valid for the data in hand can be assessed on the basis of the “distance” between observed and predicted shares. McFadden, Train and Tye (1977) proposed the following test statistic:

$$\frac{\sum_{m=1}^M (S_m - N_m \bar{P}_{jm})^2}{N \bar{P}_j} \sim \chi_{M-p-1}^2 \quad (51)$$

where the n observations in the data are first ranked from highest to lowest in terms of the predicted choice probabilities for brand j , and then sorted into M cells such that each cell contains roughly the same number of observations, S_m is the actual number of observed choices for the brand in cell m , N_m is the total number of observations in cell m , \bar{P}_{jm} is the average predicted choice probability for brand j in cell m , and \bar{P}_j is the average predicted choice probability for brand j in the total sample. If the critical value of the chi-square statistic is not exceeded, the IIA restriction is valid for the data in hand.

PROBIT MODEL

Multinomial probit – a utility theoretic exposition. Let us revisit the example of a household choosing between J brands of laundry detergents at a shopping occasion (as discussed in the section “Multinomial Logit – A Utility Theoretic Exposition”). Suppose we assume $\varepsilon_t = (\varepsilon_{1t} \varepsilon_{2t} \dots \varepsilon_{Jt})'$ to be distributed $N_J(0, \Sigma)$ we obtain the multinomial probit model (MNP). In other words, the MNP model is based on a normal distribution of errors⁶ (instead of a Gumbel distribution of errors as in the MNL model), and does not assume the errors to be *iid* (as does the MNL model). This implies that $U_t = (U_{1t} U_{2t} \dots U_{Jt})' = (V_{1t} + \varepsilon_{1t} V_{2t} + \varepsilon_{2t} \dots V_{Jt} + \varepsilon_{Jt})'$ is distributed $N_J(V_t, \Sigma)$, where $V_t = (V_{1t} V_{2t} \dots V_{Jt})'$. Since the multivariate normal cumulative distribution function (cdf) does not have a closed form, the brand choice probabilities must be written as the following J -dimensional integral.

$$\Pr(i) = \pi_{it} = \int_{\varepsilon_{1t}=-\infty}^{V_{it}-V_{1t}+\varepsilon_{it}} \dots \int_{\varepsilon_{Jt}=-\infty}^{\infty} \dots \int_{\varepsilon_{Jt}=-\infty}^{V_{it}-V_{Jt}+\varepsilon_{it}} f(\varepsilon_{1t}, \dots, \varepsilon_{it}, \dots, \varepsilon_{Jt}) d\varepsilon_{1t} \dots d\varepsilon_{it} \dots d\varepsilon_{Jt} \quad (52)$$

which can be rewritten as the following $(J - 1)$ -dimensional integral

$$\Pr(i) = \pi_{it} = \int_{\delta_{1t}=-\infty}^{V_{it}-V_{1t}} \dots \int_{\delta_{i-1t}=-\infty}^{V_{it}-V_{i-1t}} \dots \int_{\delta_{i+1t}=-\infty}^{V_{it}-V_{i+1t}} \dots \int_{\delta_{Jt}=-\infty}^{V_{it}-V_{Jt}} f(\delta_{1t}, \dots, \delta_{i-1t}, \delta_{i+1t}, \dots, \delta_{Jt}) d\delta_{1t} \dots d\delta_{i-1t} d\delta_{i+1t} \dots d\delta_{Jt} \quad (53)$$

where $\delta_{jt} = \varepsilon_{jt} - \varepsilon_{it}$. By explicitly accommodating a general covariance matrix Σ of the error terms, the probit model eliminates the IIA problem associated with the logit model. Specifically, the probit model relaxes two strong assumptions of the logit model: one, that error variances are equal across brands; two, that error covariances are zero. However, relaxing *either* of

these two assumptions of the logit model is sufficient to eliminate the restrictive IIA property of the logit model.⁷

Maximum likelihood estimation of the multinomial probit model. Given n independent observations of (X_t, Y_t) the parameters of the MNP model are estimated by maximizing the following *likelihood* function.

$$l(\beta) = \prod_{t=1}^n \pi_1(X_t)^{Y_{1t}} \pi_2(X_t)^{Y_{2t}} \dots \pi_J(X_t)^{Y_{Jt}} \quad (54)$$

which is equivalent to maximizing the following *log-likelihood* function.

$$L(\beta) = \ln[l(\beta)] = \sum_{t=1}^n \{Y_{1t} \ln \pi_1(X_t) + Y_{2t} \ln \pi_2(X_t) + \dots + Y_{Jt} \ln \pi_J(X_t)\} \quad (55)$$

Since the brand choice probabilities, $\pi_i(X_t)$, do not have a closed form (see Equation 52), their evaluation requires Monte Carlo simulation (Lerman and Manski, 1981). This involves generating g random draws from the $N_J(V_t, \Sigma)$ distribution characterizing U_t and taking the fraction of draws in which U_{it} is maximal as $\pi_i(X_t)$. As long as g is sufficiently large, the simulated value of $\pi_i(X_t)$ will be very close to its exact value (given in Equation 52). Since the maximum likelihood routine maximizes the simulated likelihood function (as opposed to the exact likelihood function), this estimation approach is also called *simulated maximum likelihood* (SML). In order to generate random draws from the $N_J(V_t, \Sigma)$ distribution, one must first simulate a g -dimensional vector $v = (v_1 v_2 \dots v_g)'$ of *iid* draws from the $N(0,1)$ distribution and then use the following equation

$$U_t = Cv + V_t \quad (56)$$

where

$$\Sigma = CC' \quad (57)$$

where C is a lower-triangular matrix with positive diagonal elements. Equation 57, also called the *Cholesky decomposition*, ensures that Σ is positive definite (which is required by the statistical regularity conditions imposed on the MNP model).

The brand choice probabilities, $\pi_i(X_i)$, can also be evaluated using a numerical approximation approach proposed by Clark (1961). In this approach, the brand choice probability is written as

$$\Pr(i) = \Pr[\max_{j \neq i} (U_{jt} - U_{it}) < 0] \quad (58)$$

where one approximates the univariate cdf of the random variable $\max_{j \neq i} (U_{jt} - U_{it})$ using recursive formulas for its mean and variance, in order to obtain the desired probability. While this approach is much quicker than Monte Carlo simulation, its bias depends on the (unknown) covariance structure of the brands' random utilities and cannot be controlled by increasing the number of observations.

Smooth recursive conditioning (SRC) simulator.

The Monte Carlo simulation procedure of Lerman and Manski (1981) employs a frequency-based simulator of brand choice probabilities. Such a simulator may be discontinuous in model parameters, which may impede numerical optimization, unless the number of draws is kept very high. Borsch-Supan and Hajivassiliou (1993) employ a Monte Carlo simulation procedure to evaluate $\pi_i(X_i)$ that is computationally superior to the frequency-based simulation procedure of Lerman and Manski (1981). Also called the *smooth recursive conditioning* (SRC) simulator,⁸ their Monte Carlo procedure is based on evaluating the $(J-1)$ -variate integral given in Equation 53. First Equation 52 is rewritten as shown below.

$$\begin{bmatrix} -\infty \\ \cdot \\ \cdot \\ -\infty \\ -\infty \\ \cdot \\ \cdot \\ -\infty \end{bmatrix} \leq \begin{bmatrix} \delta_{1t} \\ \cdot \\ \cdot \\ \delta_{i-1t} \\ \delta_{i+1t} \\ \cdot \\ \cdot \\ \delta_{jt} \end{bmatrix} \leq \begin{bmatrix} V_{it} - V_{1t} \\ \cdot \\ \cdot \\ V_{it} - V_{i-1t} \\ V_{it} - V_{i+1t} \\ \cdot \\ \cdot \\ V_{it} - V_{jt} \end{bmatrix} \quad (59)$$

which can be written in vector-form as shown below.

$$a \leq A\varepsilon_t \leq b_t, \quad A_{(J-1) \times J} = \begin{bmatrix} 1 & & & -1 \\ & 1 & & -1 \\ & & \dots & -1 \\ & & & \dots \\ & & & -1 & \dots \\ & & & -1 & & 1 \\ & & & -1 & & & 1 \end{bmatrix}$$

$$\varepsilon_t = \begin{bmatrix} \varepsilon_{1t} \\ \cdot \\ \cdot \\ \varepsilon_{it} \\ \cdot \\ \cdot \\ \varepsilon_{jt} \end{bmatrix} \quad (60)$$

where

$$a = \begin{bmatrix} -\infty \\ \cdot \\ \cdot \\ -\infty \\ -\infty \\ \cdot \\ \cdot \\ -\infty \end{bmatrix}, \quad b = \begin{bmatrix} V_{it} - V_{1t} \\ \cdot \\ \cdot \\ V_{it} - V_{i-1t} \\ V_{it} - V_{i+1t} \\ \cdot \\ \cdot \\ V_{it} - V_{jt} \end{bmatrix} \quad (61)$$

Therefore, the necessary random draws are from a *truncated multivariate normal* distribution as shown below.

$$A\varepsilon_t \sim N_{J-1}(0, A\Sigma A')$$

such that

$$a \leq A\varepsilon_t \leq b_t \quad (62)$$

which is equivalent to the following truncated normal distribution (Geweke, 1991).

$$\mathbf{e}_t \sim N(0, I)$$

such that

$$a \leq L\varepsilon_t \leq b_t \quad (63)$$

where L is the lower-triangular matrix of the Cholesky decomposition

$$LL' = A\Sigma A' \quad (64)$$

This renders the Monte Carlo simulation to be recursive as shown below⁹.

$$\begin{aligned} e_1 &\sim N(0, 1) \text{ st } a_1 \leq l_{11}e_1 \leq b_1 \\ e_2 &\sim N(0, 1) \text{ st } a_2 \leq l_{21}e_1 + l_{22}e_2 \leq b_2 \\ e_3 &\sim N(0, 1) \text{ st } a_3 \leq l_{31}e_1 + l_{32}e_2 + l_{33}e_3 \leq b_3 \end{aligned} \quad (65)$$

and so on.

This means that sequential sampling from univariate truncated normal distributions is sufficient to simulate the desired brand choice probability. Sampling from a univariate truncated normal distribution is achieved using the integral transform theorem as shown below.

$$\begin{aligned} Z &= \Phi^{-1}[\{\Phi(b) - \Phi(a)\}U + \Phi(a)] \\ U &\sim \text{Unif}(0, 1) \end{aligned} \quad (66)$$

Identifiability of probit model parameters. The identifiability of the parameters of an MNP model cannot be verified directly using the brand choice probabilities (as in the MNL model) since these probabilities do not have closed form expressions. An obvious check for identifiability is to ensure that there is no change of variable that can reduce the number of parameters in V_i and Σ . Identifiability requires one of the brand constants to be restricted to 0 (as in the MNL model), that is, to fix the location. Identifiability also requires that one brand's error variance is restricted to 1, while its error covariances are restricted to 0 (for the same reason that μ is restricted to be 1 in the MNL model), that is, to fix the scale. In more complicated versions of the MNP, one way to check for model identifiability is to check whether the Hessian matrix is negative-definite at convergence.¹⁰ However, this is neither a necessary nor sufficient condition for model identifiability. In fact, even if the MNP model is fully identified, the log-likelihood function is not necessarily globally concave. The only

way to check for global maxima is to first identify whether multiple local maxima exist (using different starting values for the parameters) and then pick the largest among the identified local maxima as the global maximum.

For marketing applications of the MNP model to scanner panel data on brand choices, see Papatla and Krishnamurthi (1992) and Chintagunta (1992). An alternative way to relax the IIA restriction is to allow the model coefficients (price, display, feature, and brand constants) in an MNL model to be random. If they follow a joint multivariate distribution, the IIA restriction is removed (even if the brand-specific errors are *iid*). Such an approach has been adopted in an independent probit framework by Hausman and Wise (1978).

OTHER NON-IIA MODELS OF BRAND CHOICE¹¹

Because of the computational burden and identification problems associated with the MNP model, marketing researchers have proposed alternative brand choice models that have tractable, closed form expressions, yet avoid the IIA restriction of the MNL model. We discuss some of these models below. All of these models can be estimated using maximum likelihood.

Generalized extreme value (GEV) model. A generalization of the MNL model, first proposed by McFadden (1978), can be written as shown below.

$$\pi_i(i) = \frac{e^{V_{it} + \ln G_i(e^{V_{1t}}, \dots, e^{V_{Jt}})}}{\sum_{j=1}^J e^{V_{jt} + \ln G_j(e^{V_{1t}}, \dots, e^{V_{Jt}})}} \quad (67)$$

where $G_i = \frac{\partial G}{\partial y_i}$, and $G(\cdot)$ is a function with the following properties.

1. G is non-negative,
2. G is homogeneous of degree $\mu > 0$, that is, $G(\alpha y_1, \dots, \alpha y_J) = \alpha^\mu G(y_1, \dots, y_J)$,
3. $\lim_{y_i \rightarrow \infty} G(y_1, \dots, y_J) = \infty$, for $i = 1, \dots, J$,
4. $\frac{\partial^l G}{\partial y^l} \geq 0$ if l is odd, and $\frac{\partial^l G}{\partial y^l} \leq 0$ if l is even.

The GEV model is consistent with random utility maximization and can be derived by

assuming the distribution of the random components of the utilities to be $F(.) = e^{-G(e^{-\varepsilon_1}, \dots, e^{-\varepsilon_J})}$. If $G(e^{V_1}, \dots, e^{V_J}) = \sum_{j=1}^J e^{V_j}$, the GEV reduces to the MNL model. If $G(e^{V_1}, \dots, e^{V_J}) = \sum_{a=1}^A (\sum_{j \in Da} e^{V_j})^\mu$, where the choice set $(1, \dots, J)$ is partitioned into A non-overlapping subsets, the GEV reduces to the *nested logit* model (described in the next section). In fact, Equation 67 shows that the GEV model extends the MNL model by making the utility of each brand depend not only on its own attributes, but also on other brands' attributes.

Nested logit model. This model allows brands to share unobserved (and observed) attributes, which induces correlations in a household's random utilities across brands. Suppose brand i can be defined as a bundle (a, b) of two attributes.

$$U_{it} = U_{abt} = V_{at} + V_{bt} + V_{abt} + \varepsilon_{at} + \varepsilon_{bt} + \varepsilon_{abt} \quad (68)$$

where V_{at} is the deterministic component of utility common to all brands that share attribute a , V_{bt} is the deterministic component of utility common to all brands that share attribute b , ε_{at} is the random component of utility due to attribute a (i.e., varies only across brands with different a), ε_{bt} is the random component of utility due to attribute b (i.e., varies only across brands with different b), and ε_{abt} is the random component of utility that varies across all brands (i.e., the "usual" random component). Assuming that the three random components – ε_{at} , ε_{bt} and ε_{abt} – are independent of each other, have zero means and variances given by σ_a^2 , σ_b^2 , and σ^2 respectively, one can show that

$$\begin{aligned} \text{cov}(U_{ab}, U_{ab'}) &= \sigma_a^2 \\ \text{cov}(U_{ab}, U_{a'b}) &= \sigma_b^2 \end{aligned} \quad (69)$$

that is, utilities across brands are correlated.¹²

The estimable version of the nested logit model is obtained by setting one of the two attribute-specific random components to zero, for example, $\varepsilon_{bt} = 0$. Further, one assumes that ε_{abt} is distributed *iid* Gumbel $(0, \mu)$, and ε_{at} is distributed so that $\text{Max}_{b \in Da} U_{abt}$ is distributed

iid Gumbel $(0, \mu')$, where Da refers to the set of all brands that share attribute a . This results in the following marginal probability of a household buying a brand with attribute a .

$$\pi_{at} = \frac{e^{\left(V_{at} + \frac{1}{\mu} \ln \sum_{b \in Da} e^{(V_{bt} + V_{abt})\mu}\right)\mu'}}{\sum_{a'} e^{\left(V_{a't} + \frac{1}{\mu} \ln \sum_{b \in Da} e^{(V_{bt} + V_{abt})\mu}\right)\mu'}} \quad (70)$$

where $\frac{\mu'}{\mu} = \sqrt{1 - \text{corr}(U_{ab}, U_{ab'})} \leq 1$. The household's *conditional* probability of buying a brand with attribute b , given choice of a brand with attribute a , is given by

$$\pi_{(b|a)t} = \frac{e^{(V_{bt} + V_{abt})\mu}}{\sum_{b' \in Da} e^{(V_{b't} + V_{abt'})\mu}} \quad (71)$$

Since only the ratio of the two scale parameters is identified, μ is usually restricted to be 1. The estimable version of the nested logit model, therefore, becomes

$$\begin{aligned} \pi_{it} &= \pi_{abt} = \pi_{at}^* \pi_{(b|a)t} \\ &= \frac{e^{\left(V_{at} + \ln \sum_{b \in Da} e^{V_{bt} + V_{ab}}\right)\mu'}}{\sum_{a'} e^{\left(V_{a't} + \ln \sum_{b \in Da} e^{V_{bt} + V_{ab}}\right)\mu'}} \\ &\quad * \frac{e^{V_{bt} + V_{abt}}}{\sum_{b' \in Da} e^{V_{b't} + V_{abt}}} \end{aligned} \quad (72)$$

where $\mu' \leq 1$. If $\mu' = 1$ this model reduces to an MNL model. The nested logit model can be understood using a *tree-structure* where the upper level represents the household's choice of attribute a , and the lower level represents the household's choice of attribute b conditional on the choice of attribute a . With three attributes, the estimable nested logit model looks as shown below.

$$\pi_{it} = \pi_{abct} = \pi_{at}^* \pi_{(b|a)t}^* \pi_{(c|ab)t}$$

$$\begin{aligned}
 &= \frac{e^{(V_{at}+V'_{at})\mu''}}{\sum_{a' \in D} e^{(V_{a't}+V'_{a't})\mu''}} \\
 &\quad * \frac{e^{(V_{bt}+V_{abt}+V'_{abt})\mu'}}{\sum_{b' \in Da} e^{(V_{b't}+V_{ab't}+V'_{ab't})\mu'}} \\
 &\quad * \frac{e^{V_{ct}+V_{bct}+V_{act}+V_{abct}}}{\sum_{c' \in Dab} e^{V_{c't}+V_{bc't}+V_{ac't}+V_{abct'}}} \quad (73)
 \end{aligned}$$

where

$$\begin{aligned}
 V'_{abt} &= \ln \left(\sum_{c' \in Dab} e^{V_{ct}+V_{bct}+V_{ac't}+V_{abct'}} \right) \\
 V'_{at} &= \frac{1}{\mu'} \ln \left(\sum_{b' \in Da} e^{(V_{b't}+V_{ab't}+V'_{ab't})\mu'} \right) \\
 \mu' &\leq 1, \mu'' \leq \mu' \quad (74)
 \end{aligned}$$

If $\mu'' = \mu'$ this model reduces to the MNL model. While the nested logit model presents a parsimonious way of modeling inter-brand correlations, determining the sequence of attributes in the tree is a subjective decision. Some authors prescribe the estimation of nested logit models with all possible orders of attributes, and pick whichever best describes the observed data. For an application of the nested logit model to scanner panel data on brand choices, see Kannan and Wright (1991).

Batsell and Polking (1985) model. This model allows the ratio of a household's choice probabilities for brands i and j to depend on other brands in the household's choice set. Specifically,

$$\beta_{ij}^A = \ln \left(\frac{\pi_i^A}{\pi_j^A} \right) = \sum_{I \subset [A - \{i,j\}]} \alpha_{ij}^I \quad (75)$$

where A is the household's choice set, that is, a subset of the full set of brands $\{1, \dots, J\}$. This implies that the ratio of the brands' choice probabilities is a function of the brands in the choice set A . For example, if $A = \{i, j\}$, $I = (\{\emptyset\})$ and $\beta_{ij}^{ij} = \alpha_{ij}^{\emptyset}$. If $A = \{i, j, k\}$, $I = (\{\emptyset\}, \{k\})$ and $\beta_{ij}^{ijk} = \alpha_{ij}^{\emptyset} + \alpha_{ij}^k$. If $A = \{i, j, k, l\}$, $I = (\{\emptyset\}, \{k\}, \{l\}, \{k, l\})$ and

$\beta_{ij}^{ijkl} = \alpha_{ij}^{\emptyset} + \alpha_{ij}^k + \alpha_{ij}^l + \alpha_{ij}^{kl}$. The estimable version of this model is given below.

$$P_A(i) = \frac{\prod_{I \subset A} e^{s_i^I}}{\sum_{k \in A} \prod_{I \subset A} e^{s_k^I}} \quad (76)$$

where

$$\begin{aligned}
 s_i^I &= 0 \text{ for } i \notin I \\
 \sum_{i \notin I} s_i^I &= u_I \quad (77)
 \end{aligned}$$

where u_I is a pre-assigned number. If $s_i^I = 0$ for $I \neq \emptyset$, this model reduces to the MNL model. Once the estimates for s_i^I 's are obtained, the α_{ij}^I 's are given by

$$\alpha_{ij}^I = s_i^{iI} + s_i^{ijI} - s_j^I - s_j^{ijI} \text{ if } I \cap i, j = \emptyset \quad (78)$$

While this model relaxes the IIA restriction of the MNL model in a more flexible manner than the nested logit model, it involves the estimation of a large number of parameters. Further, unlike the GEV or nested logit models, this model cannot be derived from random utility maximization.

Alternative approaches. The *elimination-by-aspects* (EBA) model of (Tversky, 1972) works on the idea that a household sequentially screens brands based on attributes in order to arrive at an optimal brand choice. This model does not have the IIA property. A *consideration set model* explains a household's brand choice as an outcome of a two-stage process, where the first stage involves the formation of a consideration set, and the second stage involves the optimal choice of brands within the consideration set (see, for example, Roberts and Lattin, 1991). Such a two-stage model also does not have the IIA property. In general, a brand choice model that is consistent with two-stage decision-making on the part of the household eliminates the IIA restriction. Similarly, any brand choice model that allows a brand's utility to depend on the attributes of competing brands (for example, the GEV model) ends up eliminating the IIA restriction. Models that obey this property are called *mother*

logit models. While a large number of non-IIA brand choice models have been proposed in the marketing literature, the most popular (in terms of the number of academic papers published on the model) are the multinomial probit and the nested logit models. Among these two, given the sharp rise in computational power in recent years and the natural appeal of the normal distribution to statisticians and econometricians, the multinomial probit model has come to be accepted as the *de facto standard* for brand choice models. Another reason for the increasing popularity of the multinomial probit model is that it provides a more flexible framework to accommodate the effects of unobserved heterogeneity, state dependence, and so on.

ENDNOTES

¹ It is on account of these random components that brand choice models are also called *random utility models*.

² It is useful to note that this parameter vector is common across brands.

³ This is what renders asymptotic properties of estimators to be much more convenient to work with than small-sample properties.

⁴ If $\hat{\beta}$ is a vector, the asymptotic variance of the MLE is a matrix \sum , and asymptotic efficiency implies that $(\sum^* - \sum)$ is *non-negative-definite*, where \sum^* is the asymptotic variance of any other consistent estimator of β .

⁵ The exposition of these problems borrows heavily from Batsell and Polking (1985).

⁶ If one viewed the error term to be the sum of a large number of unobserved but independent components, by the *central limit theorem* the error term will tend to be normal.

⁷ The probit model solves the *similarity problem* associated with the IIA property (see section on the IIA property), however, the *dominance* and *regularity* problems still remain.

⁸ Also called the Geweke-Hajivassiliou-Keane (GHK) simulator, this simulator has been shown to be superior to other simulation algorithms in terms of RMS error by Hajivassiliou, McFadden, and Ruud (1996).

⁹ This recursive scheme is also called a *Gibbs cycle* (Geweke 1991).

¹⁰ Since optimizers in software packages such as Gauss, SAS, and others, are *minimizers*, maximum likelihood estimation entails minimization of the negative log-likelihood function. In such a case, the Hessian matrix must be *positive-definite*.

¹¹ The discussion of the GEV and Nested Logit Models in this section are borrowed from Ben-Akiva and Lerman (1985).

¹² The MNL model, by ignoring attribute-specific random components, that is, ε_{iat} and ε_{ibt} , restricts σ_a^2 and σ_b^2 to be zero.

opportunities and challenges in social marketing

Alan R. Andreasen

BRIEF HISTORY

Social marketing has two points of origin, one in the practical world and one in academia. The first instance of application of marketing concepts and tools in a social context is found in family planning programs in India in the late 1960s. Despite significant inputs of international aid, families in underdeveloped and developing countries were becoming worse off because family size growth was outpacing economic growth. At the time, public health programs were minimally effective in part because of their poor reputations and frequent inaccessibility.

A visiting professor at the Indian Institute of Management at Calcutta (IIMC), Peter King, along with businessmen, IIMC professors, and the Ford Foundation brought out the document "Proposals for Family Planning Promotion: A Marketing Plan" in 1964. The concept was to package and advertise branded, donated products and have them distributed by six cooperating international marketers including Hindustan Lever, Lipton, and Union Carbide. The Nirodh program became the world's largest social marketing effort and remained so until the mid-1990s.

In the same period as the Nirodh start-up, the marketing faculty at Northwestern University fomented a sea change in the academic view of marketing by proposing that it be broadened beyond its commercial confines, arguing that "every organization performs marketing-like activities whether or not they are recognized as such ... marketing is a pervasive activity that goes considerably beyond the selling of toothpaste, soap and steel." Two key members of the Northwestern faculty, Philip Kotler and Gerald Zaltman, focused on a particular set of applications which they called for the first time *social marketing* (Kotler and Zaltman, 1971).

Initial academic opposition to the broadening concept (marketing implies "markets") quickly retreated and a number of academics in the United States, many of whom were influenced by the social unrest provoked by the Vietnam

war, began to investigate and write about social marketing applications. At the same time, select advertising and public relations organizations such as Porter Novelli began to take on clients with social challenges and existing consulting organizations such as The Futures Group, Population Services International, and the Academy for Educational Development also secured social marketing contracts from government agencies such as USAID (United States Agency for International Development), CDC (Centers for Disease Control and Prevention), and the World Bank.

The growth of interest in social marketing on the scholarly and practical sides approximated a typical diffusion process which is still in the growth phase. Research and applications grew relatively slowly at first because, on the academic side, articles of top journal quality were slow in appearing and, on the practical side, because clients were often unfamiliar with or confused about the concept. Both impediments have largely been overcome.

There are now at least eight textbooks and various specialized volumes. The field has its own journal, the *Social Marketing Quarterly*, and social marketing articles routinely appear in the *Journal of Consumer Research*, *Journal of Public Policy and Marketing*, and other major journals around the world. There are reading books on social marketing ethics, annual conferences, and special sessions within other mainstream conferences that are now devoted to social marketing. Chapters on social marketing appear in books in nonmarketing disciplines such as health promotion and health communication. Social marketing as a strategic platform has been introduced into US agencies like the Centers for Disease Control and Prevention and into a range of UK programs of the National Health Service.

DEFINITIONAL CHALLENGES

One of the early – and in one respect continuing – problems for social marketing was confusion about what the term meant and how it differed from nonprofit marketing, socially responsible marketing, social advertising and, most recently, social network marketing. In the earliest period, social marketing was seen as product marketing (as in the family planning work and later in many

2 opportunities and challenges in social marketing

child survival medical interventions). However, the field slowly evolved to encompass service applications (mammography screening and drug counseling campaigns) and eventually “pure behaviors” (recycling and walking more). Along the way, given the dominance of health applications, it faced challenges to differentiate itself from health education or health communication. A further source of confusion was scholars and promoters who claimed that it encompassed the marketing of *ideas*, which led critics to argue that it was just a fancy version of advocacy or propaganda. Many asked: “Isn’t this what the Advertising Council has been doing since World War II?”

By the mid-1990s, a consensus emerged around the fundamental notion that the objective was to influence *behavior* and not just attitudes or knowledge. It was argued that the commercial marketers whose concepts and tools social marketers apply do not settle for program impacts solely on knowledge and attitudes. If marketing efforts do not result in sales, marketing managers or advertising agencies are not rewarded and campaigns – even products and brands – are scrapped. This author’s own definition is that social marketing is the application of commercial marketing concepts and tools to influence the voluntary behavior of target audiences to improve their lives or the society of which they are a part. It is made clear that the goal is to influence *problem* behaviors; not simply behaviors like voting, charitable giving, or attending the arts. The latter fall into the realm of nonprofit marketing more broadly construed.

The focus on behavioral outcomes also distinguishes it from social advertising which has communication goals which may be needed to provoke or assist a behavioral outcome. It is also distinguishable from social network marketing which also can be a tool of social marketing but is not equivalent to it.

Two more definitional challenges revolve around social marketing strategy rather than tactics. The first is whether social marketing can be used to promote racial discrimination or Aryan superiority. The author’s own view is that social marketers are behavior influence specialists – as are marketers in the private sector. The choice of objectives and overall goals

of some strategy is not their province – although they may provide advice on feasibility. Social marketers need to make ethical choices about the strategies to which they lend their talents – as do commercial marketers asked to promote cigarette brands.

The second strategic issue is whether social marketing should focus solely on individuals or groups exhibiting – or likely to exhibit – problem behaviors, what is often referred to as *downstream* targets. Michael Rothschild (1999) proposed that social marketing scholars and researchers pay more attention to the distinction made by MacInnis, Moorman, and Jaworski (1991) that behaviors – both commercial and social – require three preconditions – the *motivation* to act, the *opportunity* to act, and the *ability* to act (often denoted by the acronym MOA). The obesity crisis has provided a particularly compelling example of the need to focus strategically not just on overweight kids and their families but also on what social marketers call *upstream* targets – school administrators who can change cafeteria menus, banish soft drink machines, and add physical education classes, or city council members who can provide playgrounds or increase police protection in areas where obese kids might play.

In his most recent book Andreasen, (2007), the author has made the case that social marketing has a proper role to play in influencing upstream targets as well as those who exhibit – or might exhibit – problem behaviors. This point deserves expansion here.

“CONSUMER” BEHAVIOR

First, a conceptually important distinction in social marketing is that its definition focuses on “target audiences” and not “consumers.” The distinction was made early on, in part, to make the application of marketing concepts and tools more palatable to those in the social sector who considered marketing as somehow evil. However, it also reflects the fact that the objective of many social marketing campaigns is not “consumption.” The focus is behavior. In the private sector, the behavior in question is acquisition and consumption of specific goods or services by *consumers*. In social campaigns, such as those directed at exercise or recycling, it is

confusing – even off-putting – to imply that the goal is to influence some sort of “consumption.” As a consequence, this author has advocated the more general – and more encompassing – term of *target audience behavior*, a term that subsumes both commercial and social objectives.

This is not merely a semantic challenge. It may be argued that marketing is all about influencing behavior. Creating intellectual silos, wherein social marketing is seen as somehow different and a special (and minor) area of application of marketing concepts and tools, is a taxonomic construct that inhibits the opportunity to create a more generic view of the field. That is, we should ourselves, as behavior influence researchers, seek commonalities across behavioral contexts. For example, rather than dividing the field into purchasing and social behaviors, would we not advance the field further if we ask more generic questions about behavioral influence? For example, how does achieving the goal of *starting* a behavior differ from *continuing* a behavior or *switching* a behavior? What do we know about stopping a behavior? Is preventing someone from engaging in a behavior (stealing videos, using drugs, engaging in risky sex) different from getting them to start a behavior? Are there general principles that apply across sectors in starting or switching behaviors?

Further, if influencing behavior is our strength, then can we consider efforts to influence upstream individuals a legitimate subject of interest? Is getting a city council member to vote “yes” to fund a school playground in a poor neighborhood an example of influencing target audience behavior? What of cafeteria managers, editorial directors at TV stations, or the person who decides what information goes on menu boards at a Burger King? The author’s argument is that the answer is yes and, further, many of these situations would present opportunities to study *stopping* behavior in more depth.

There are already a number of commonalities in the way that marketing managers in both sectors approach their behavioral challenges. The commercial concept of value creation, for example, is equally relevant in both sectors. A social marketer seeks to offer target audiences compelling value propositions comprising attractive benefits and minimal costs so as to provoke a desired behavioral outcome in which

benefits are exchanged for costs (Bagozzi, 1978; Bagozzi and Warshaw, 1990). Thus, the truth[®] campaign of the American Legacy Foundation has the goal of inducing teenagers not to take up smoking (a behavioral outcome). The campaign offers the target audience *benefits* such as a sense of pride in not being manipulated by the tobacco industry and a feeling of comradeship in being part of an “anti-tobacco movement of teens.” These benefits have been found to more than compensate for the costs of not having specific (smoker) friends or enduring the taunts of teen smokers who implicitly argue that smoking is “cool.”

The future of “consumer behavior” research should include special issues of major journals and conference sessions on switching, stopping, and starting behaviors along with those on brand preference, cognitive processing, and customer satisfaction. Further, one would hope that scholars interested in the latter topics would, from time to time, ask whether and how their theories and findings would apply in different realms, not just in the commercial marketplace.

TARGET AUDIENCE BEHAVIORAL RESEARCH

Social marketing comprises an area of application of marketing concepts and tools similar to B2B marketing and services marketing. Textbooks and strategic plans therefore insist on thorough target audience research in planning interventions, pretesting of such interventions, and regularly tracking progress.¹ Social marketing applications also urge sophisticated segmentation approaches and close attention to positioning and branding possibilities.

The research in the area of social marketing divides into three broad categories. First, there are macrolevel evaluation studies that seek to ascertain whether a particular intervention yielded desired effects and, where possible, which elements of the specific campaign seemed to have been most impactful. Second, there are midlevel studies of particular tactics, typically variations on communication approaches. Third, there are microlevel studies that seek to discover mental processing pathways between inputs and desired effects.

Typical of macrolevel research is an evaluation of 54 social marketing programs carried out

4 opportunities and challenges in social marketing

in 2006 by Stead *et al.* (2007). The authors' conclusions are characteristic:

A majority of the interventions, which sought to prevent youth smoking, alcohol use and illicit drug, use reported significant positive effects in the short term. Effects tended to dissipate in the medium and longer term, although several of the tobacco and alcohol interventions still displayed some positive effects two years after the intervention. These results are broadly comparable with systematic reviews of other types of substance use prevention interventions The evidence is more mixed for adult smoking cessation, although small numbers of programmes were nonetheless effective in this area. There is modest evidence of impact on levels of physical activity and psychosocial outcomes, with an apparently weaker effect on physical activity related physiological outcomes.

Two well-funded campaigns in the United States that represent social marketing success stories are the VERB campaign of the Centers for Disease Control and Prevention and the truth[®] campaign of the American Legacy Foundation. The VERB campaign used sophisticated branding and media approaches focused on children 9–13 years as well as upstream influencers. It used “commercial marketing methods to advertise being physically active as cool, fun, and a chance to have a good time with friends.” Baseline and 1-year follow up surveys of 3120 parent–child dyads were conducted in 2002 and 2003. Huhman *et al.* (2005) concluded that “The VERB campaign achieved high levels of awareness in 1 year.” They also noted particularly marked effects on the behavior of younger children, girls, children whose parents had less than a high school education, children from urban areas that were densely populated, and children who were “low active at baseline.” (Ironically, after spending \$339 million over 5 years, funding for this successful campaign was withdrawn in 2006).

The truth[®] campaign has a much longer history. It began under the Florida State Government with funding from one of four early settlements of state suits against the tobacco industry and migrated to the American Legacy Foundation which was created with funding from the subsequent master settlement negotiated with 48 states and the District of Columbia.

The campaign achieved dramatic effects on smoking initiation in Florida, results that are paralleled in research on the national campaign (Farrelly *et al.* 2002).

Midlevel and microlevel social marketing research studies both exhibit a key difficulty in modeling and understanding social marketing effects at the micro and campaign level. Despite an earlier argument that marketing is all about behavior, whatever the sector, it is the case that behaviors to be influenced in the social sector often have one of three characteristics:

1. There is no observable behavior that one can measure that would mark behavioral outcomes – for example, not smoking and not using drugs.
2. The objective is to instill a future pattern of repeated behaviors – for example, exercising regularly, advancing girls' education and employment in developing countries, regularly taking one's medicine, and recycling.
3. The major benefit constitutes an expectation (promise?) of something that takes place many years in the future – for example, a longer life – or that comprises a “nonoutcome” such as a stroke or breast cancer both of which may be perceived as probabilities of such outcomes.

As a consequence, considerable focus in social marketing research has been on measuring and tracking *intentions* to behave. Fortunately, these intentions have been a key measure in commercial consumer behavior research especially in microlevel consumer behavior experiments. It has also been a particular focus in the area of health marketing where perhaps 80–85% of social marketing applications have been initiated. The latter has the important advantage for those eager to conduct target audience research in social marketing that there exists a significant body of theory and research, much of it seeking to explain or predict socially important behavior from measures of intentions.

A useful summary of much of this work is provided in the comprehensive 2006 meta-analysis by Webb and Sheeran (2006) of 47 experimental studies of the linkage between intentions and behavior change.² The models

that undergirded many of these studies will be familiar to traditional marketing scholars. Eighty-one percent were grounded in one of four models. The most common (29%) was Fishbein and Ajzen's Theory of Reasoned Action (TRA) or the modification in Ajzen's Theory of Planned Behavior (TPB). This was followed by Bandura's social-cognitive theory (21%), Ronald Rogers' Protection Motivation Theory (18%), and Hochbaum and Rosenstock's Health Belief Model (13%). As most consumer behavior researchers know, the TRA/TPB models specify that intentions and ultimately behaviors are driven by three factors: (i) beliefs about outcomes and the evaluation of those outcomes; (ii) normative beliefs about the wishes of significant others and the motivation to comply with those wishes; and (iii) self-efficacy – "control beliefs and perceived power." Other factors that can influence these three central components as well as factors that potentially impact the link between intentions and behavior are summarized by Fishbein and Cappella (2006). The potential modifiers between intentions and behavior are environmental factors and skills and abilities. Six sets of background factors can influence behavioral, normative, and control beliefs. These are

- past behavior;
- demographics and culture;
- attitudes toward targets (stereotypes and stigma);
- personality, moods, and emotions;
- other individual difference variables (perceived risk);
- intervention exposure and media exposure.

Bandura's model focuses primarily on self-efficacy beliefs – one's ability to act and to secure a specific outcome. Roger's Protection Motivation Model emphasizes individual perceptions of vulnerability to health threats and appraisals of their coping skills – the perception of the efficacy and costs of recommended responses, The Health Belief Model is similar in that it assesses individual's perceptions of health threats and their ability to favorably respond to them. These models are often used by social marketing researchers as in Pechmann *et al.*'s use of the protection motivation model to assess

the effectiveness of antismoking advertisements on adolescents (Pechmann *et al.*, 2003).

All of these models focus on factors influencing intentions. Webb and Sheeran (2006) particularly focused on the extent to which intentions actually led to behavior. Three sets of factors were considered: the theoretical base and the methods and perceived sources of the intervention. Of potential future research interest was the finding that intentions were less predictive of behavior under two conditions – prior habit formation and social reactions to the particular health behavior.

Social reactions have been of particular interest to Robert Cialdini and colleagues. Cialdini found that perceived social norms have a strong effect on actual behaviors. Ironically, he also found that subjects in their studies perceived norms to be much less influential than they actually were (Kallgren, Reno, and Cialdini, 2000; Nolan *et al.*, 2008).

Many approaches to socially important behaviors have considered intentions as a variable represented as probabilities of action. To augment this approach, Prochaska and DiClemente introduced what they called the *Transtheoretical Model of Behavior*. The focus of this approach is that, for the high involvement kinds of behaviors that are the focus of much social marketing research, it is more reasonable to think of target individuals proceeding not in a single step from considering a behavior to acting on it (or not). Rather, these researchers proposed that target audiences proceed through six "stages of change." These are as follows:

- Precontemplation – where the target audiences are either unaware of the need for the behavior or consider it not of relevance for them.
- Contemplation – where they are actively considering the action – a stage that can take considerable time and which has been thought of as "early" and "late" contemplation.
- Preparation – where the individuals have decided to go forward and are, perhaps, assembling the necessary skills, social support, and the like to accomplish the behavior.

6 opportunities and challenges in social marketing

- Action – where the individuals are undertaking their initial attempts at behavior change (which may be all that is needed, for example, securing an important inoculation).
- Maintenance – where the individuals take up a new pattern of behavior and, preferably, make it a habit.
- Termination – either abandoning or completing a course of action.

Their model has been applied with considerable success to such behaviors as smoking, drinking, condom use, responsible eating, and exercise (Prochaska, DiClemente, and Norcross, 1992; Prochaska and Velicer, 1997).

RECENT DEVELOPMENTS

The twenty-first century has seen a number of significant developments that raise important opportunities for research. First, as noted earlier, social marketers have begun to pay more attention to environmental factors that often provide significant social influence. Social norms (already cited) are one set of factors. Social norms, of course, are themselves not fixed. They both evolve over time and are themselves potentially capable of being influenced. In this regard, the author has suggested elsewhere that social marketers investigate the formation and influence of social agendas. Important precursors of social influence may be the relative importance of the behavior on the general public agenda. Such agendas ebb and flow in particular stages and are very often influenced by media agendas.

A second recent focus that reflects attention to upstream factors is the attention to behavioral economics. This line of thinking stems from conservative thinkers who are reluctant to promote strong campaigns to change behaviors but, instead, argue for changes in environmental conditions that can “nudge” people toward doing the right thing (Thaler and Sunstein, 2008). Wansink’s series of studies on such influences on overeating suggest possible courses of research along these lines (Wansink, 2004).

A third development has been an expansion of the areas of interest beyond health care. As environmental issues rise on political or public agendas, more social marketers are exploring intervention alternatives. McKenzie-Mohr and

Smith (1999) have emphasized that such issues call for much more attention to community involvement in solutions. In a different realm, Lusardi, Keller, and Keller (2009) have used social marketing concepts to study financial decision making.

A fourth important development is the merging of social marketing interests with those of social entrepreneurs including corporations. In recent years, private sector businesses have increasingly become interested in bringing about social change (Hess, Rogovsky, and Dunfee, 2002). They do so, not because they are generous and big – hearted – although they may be – but because they envision potential strategic payoffs to their own bottom lines. For example, Hindustan Lever has found that it could create a longer lasting, smaller bar of Lifebouy soap, thereby combating sanitation challenges and expanding the total market. Coca Cola found that it needed to bring its marketing and promotional skills to bear on the HIV/AIDS crisis in Africa where it found many of its workers afflicted with the disease.

FUTURE RESEARCH NEEDS

As several leading scholars with interests in social marketing have said, the potential for innovative research in noncommercial settings is significant. Part of this is due to several characteristics of the behaviors that social marketers are attempting to influence. Among these are behaviors where

1. there are no concrete products or services involved – for example, exercise;
2. they are really *non* behaviors – for example, not smoking, not engaging in violence against spouses or children, and not using drugs;
3. they promise unobservable benefits (without instrumentation) – for example, lowered blood pressure;
4. they promise benefits long in the future – for example, longer life from exercise or better diets and a happier retirement from today’s savings;
5. they often require significant trials before success is achieved – for example, stopping smoking or losing weight;

6. the behaviors are heavily influenced by significant others – for example, health practices of young African women under the watchful eyes of their mothers-in-law;
7. the benefits of the behavior accrue to others while the costs are personal – for example, recycling;
8. interventions are constrained by public scrutiny or by social norms – for example, HIV/AIDS campaigns in many countries and family planning initiatives by the US government (especially under conservative administrations).

There is also an intriguing challenge that, to the author's knowledge, has not been addressed in consumer behavior studies in commercial settings. This is the fact that, in social marketing campaigns, there are often multiple *types* of target audiences that will be affected by a particular campaign or tactic but may not respond in the same way. Resources for social marketing campaigns come from five principal sources: revenues from clients (e.g., Goodwill clothing sales), funding by foundations, government contracts, individual donations, volunteer commitments, and various forms of involvement by corporations. Typical consumer behavior research assesses responses – or likely responses – for a single type of target – consumers. In nonprofit contexts, it may be that volunteers or donors will respond differently (and perhaps negatively) to tactics that are positively effective with donors or foundations. What if alternative AIDS campaign messages yield different responses from at-risk populations, volunteers, and corporate partners? How does one choose among them?

Branding is potentially highly valuable for social marketing programs. It has been used to brand specific products (e.g., Nirodh condoms) or services (Family of the Future health clinics). However, there are two problems for campaigns that do not involve products or services. What, for example, should branding's role be in tackling the obesity problem? Is there "customer value" to be derived from branding an intervention to get someone eating better or exercising more? Will there be more frequent or more lasting outcomes if a target audience member follows the recommended behaviors of a branded social

marketing campaign? Are slogans – *Don't Mess with Texas* or *Click It or Ticket* – equivalent of brands?

Another challenge alluded to above is the fact that many desirable social outcomes require that the target audience adopt a different behavioral pattern – often over a lifetime – whether it is a better diet, regular exercise, condom use, recycling, and so on. Experience shows that lifestyle changes often suffer setbacks and reversals. Sometimes, it is because the behavior seems difficult (regular exercise) or because outcomes are not obvious on a daily basis (lowered blood pressure). How does one study cognitive processes yielding not just a one-time behavior but a pattern of future behaviors? Useful beginnings are found in Bagozzi and Warshaw's, 1990 "theory of trying." More recent research by Kahn and Luce (2003) may add to this by looking at the role of feedback on continued behavior, in their case, the impact of "false positives" from mammographies on repeated test-taking.

Another research need is to pay more attention to intervention strategies other than communications and message alternatives. It is understandable that those describing and investigating social marketing interventions would focus on communications. Clever and unconventional advertising approaches are seductive as a means of describing and bragging about campaign performance. (Indeed, the author's colleagues have observed that his own writings often exhibit this tendency.) There are three fundamental problems with this distorted emphasis.

First, it offers ammunition to those who argue that we bring nothing to problematic areas that are already dominated by communications specialist. Second, it sorely underutilizes marketing's robust armamentarium – for example, other elements of the "4Ps." In the early family planning programs, a critical contributor to success was the establishment of far flung and *reliable* distribution networks for family planning products. This was essential to a poor mother seeking to limit her family size because she could rely on the availability of a new cycle of oral pills when she had enough money to buy another round. Equally important was the pricing of family planning products. Research has shown that free products are perceived as of lower quality and reliability than

products (and services) that cost something, but how much? Rules of thumb were used initially but this is one of those realms where careful target audience research by marketing scholars could not only help organizations make tactical decisions about pricing but also broaden our understanding and interpretation of pricing signals by the poor and not-so-poor. Such research would also have the virtue of fueling arguments against social critics who rail against social marketing approaches that charge anything to the poor as immoral.

Third, it reinforces the myopic view that all that is needed for the desired behavioral influence that the target audience be sufficiently motivated. However, as Rothschild and others keep emphasizing and the cognitive models of Fishbein and others make clear, social behaviors also require that target audiences have the ability and opportunity to act and keep acting. This requires social marketing scholars to pay greater attention to influencing the behaviors of upstream target audiences, not typically considered to be “consumers” in the way the term is construed in traditional texts. That is, for a society to have major impact on childhood obesity, school administrators have to provide better lunches and breakfasts and safer school playgrounds. Similarly, McDonald’s marketers need to bring marketing skills to the problem and legislators (sometimes) have to pass laws requiring better food labeling, bans on trans fats and/or funding for new parks and bike paths.

If consumer behavior research is about influencing behaviors to increase desirable organizational outcomes (more profits, more donations, or more grants) and if we extend our consideration to the task of improving individual and societal welfare, then can we not consider a school administrator an important target audience whose behavior is needed to yield better social outcomes? If so – as I believe it is – then this opens up a dramatic new array of opportunities to study a whole new class of targets and potentially advance our understanding of how marketing’s 4Ps can influence target audiences to protect the poor from poverty and disease, improve the world’s physical environments, and improve the health and financial well-being of all.

ENDNOTES

¹ This contrasts with historical social science approaches to project research that emphasized benchmarking and project-end evaluations.

² The 47 studies were selected out of a broader universe of 221 studies in that both intentions and behavior were measured and that the latter measures were separated in time. That is, intentions were measured and behavior was tracked at some later point.

brand community

Utpal M. Dholakia and René Algesheimer

INTRODUCTION

Much of consumer behavior is social, impelled by social motives and joint decision-making processes, shaped by socially constructed and shared information, and governed by social norms, influences, rituals, traditions, and taboos. Over the last decade, consumer researchers have increasingly turned their attention to social processes. Among other things, they have studied family and couples decision making, social influences on consumer decision making and self-regulation, consumer subcultures, and the effects of community on consumer choices, attitudes, and behaviors.

A social concept that has emerged as important in explaining and understanding consumer behavior is that of a consumer collective called a *brand community*. The concept of brand community is powerful because it reflects both social process and cultural meaning, stems from a number of converging environmental trends such as the ascendance of the Internet, the decline of traditional family and community, and the growing power of individual consumers in marketplace transactions, and influences consequential marketing outcomes. In this article, we elaborate on this concept by providing a definition of brand community, introduce and elaborate on different types of brand communities, and examine the consequences of consumer participation in them.

DEFINITION OF A BRAND COMMUNITY

Brand communities serve many different functions for consumers and firms. For consumers, brand communities act as conduits of information, channels for solving product-related problems and learning how to use its features, places for finding new friends for social support and for meeting existing friends, and as a means for self-expression through creation and sharing of symbolic content. For firms, brand communities are low-cost, high-efficacy marketing programs which can achieve a number of different marketing objectives simultaneously: the

abilities to conduct quick and low-cost marketing research with the target audience, deliver prompt customer service at low expense, educate and socialize new customers, strengthen attachment to the firm's brand for existing customers, and increase the frequency and loyalty of customer purchase behaviors.

We define a *brand community* as a *collective of consumers organized around one particular brand, which is sustained through repeated online and/or offline social interactions and communication among its members who possess a consciousness of kind, feel moral responsibility toward one another, and embrace and propagate the collective's rituals and traditions*. Several aspects of this definition are important and worth elaborating on.

Role of brand in brand community. First, a brand community is a social collective organized around one particular brand, which means that the collective comprises of consumers who have at least some heightened enduring interest in that brand. Such an interest may stem from an attachment to the brand itself, from a more general interest in the product category to which the brand belongs, or (more likely) both. In the prototypical example of a brand community involving Harley Davidson Motorcycle owners, the so-called HOG (Harley Owners Group), many members have a fanatical devotion to the Harley Davidson brand, and view the biker lifestyle symbolized by the brand in idealistic terms. Generally speaking, brand community members are among the most ardent enthusiasts of the brand. Consumer researchers have found brand communities comprised of enthusiasts to exist across a range of product categories, from highly complex technological products like enterprise software (e.g., Oracle and Hewlett Packard) and construction equipment (e.g., John Deere), to consumer durables like virtually all brands of cars, motorcycles, and video game consoles, to low-cost consumable food brands like the Nutella chocolate hazelnut spread, Coca-Cola, and Starburst candy.

Role of communication in brand community. The second part of the definition explains the process by which the brand community sustains itself. Regular social interactions and communication

2 brand community

between members, accomplished through online channels such as bulletin boards, chat-rooms, and email lists, and via offline means such as face-to-face meetings, events, and gatherings, is essential not only for the community's business to be conducted but also, perhaps more importantly, for the relationships between community members to form and strengthen. It is through timely and convenient communication ability that the brand community is able to solve the problems of individual members, deliver technical service and support to them, generate consumer feedback and new product ideas, and deepen participants' knowledge of one another and the strength of their relationships. For individual participants, communicating with others within the brand community serves specific functional purposes such as solving a particular product-related problem or learning how to use a product feature, or may simply provide the means to have a pleasant and enjoyable communal experience.

The essential markers of brand community. The remaining part of our brand community definition describes the three markers that sociologists stipulate as essential for any social collective to be truly considered a community: (i) a consciousness of kind, (ii) a sense of moral responsibility, and (iii) the knowledge and acceptance of the collective's rituals and traditions.

The first core marker of community, the so-called *consciousness of kind*, refers to the intrinsic connection that community members feel toward one another through a sense of belonging to the group, and a sense of difference or separation from those who are nonmembers. Consciousness of kind is the force driving the cognitive categorization of in-groups and out-groups and biased behavior favoring the in-groups by consumers, and a primary reason why brand communities are such effective marketing programs. Compared to advertising or direct marketing, brand communities muster the consumers' intrinsic interests and motivations in support of the brand, and in opposition to competing brands. For example, Harley Davidson riders belonging to a HOG believe that they share similar attributes, values, and views of life, and thus feel intrinsically connected to each other. At the same time, they

may view riders of other brands such as those who own Honda or Suzuki motorcycles in a negative light. Such beliefs and feelings strongly influence their behaviors.

As Cova 1997 points out in introducing the notion of "linking value," even if brand community members have never met before in a face-to-face setting (as is often the case with brand community participants), they can still experience the connection and the feeling that they know one another. The common social link shared with other members through their interest in the brand sustains the community, even without actual physical interaction among its members.

The second core community marker is a feeling or sense of moral responsibility or obligation toward the community itself and other brand community members, and may include a concern for their well-being as expressed through acts of help or social support such as by teaching newer members how to use the product, and educating them about the practices and norms of the community. The sense of moral responsibility can extend to the community as a whole, and is evident when members make the effort to enforce communal rules and shared values such as fairness, and go out of their way to recruit new members to the community. Usually, such a sense of responsibility is cultivated over time as a member participates in and comes to identify with the community. It deepens with the consumer's experience and tenure in the brand community.

Muniz and O'Guinn (2001) insightfully observed that brand communities are *communities of limited liability* in the sense that for individual consumers they are intentional, voluntary, and partial in the level of involvement they engender, yet are vital to contemporary life and convey significant meaning to the consumer.

The third core community marker is the knowledge and acceptance of the brand community's shared rituals and traditions by its members. As a social collective matures into a community, it develops various rituals and traditions. In an important way, it is these rituals and traditions, which may include such things as narratives of the brand's origins and history, celebrations, brand stories and myths, and ritualistic utterances and actions, which

create the sense of the in-group and affirm the cohesiveness of brand community members. For example, it is customary for members of eBay's brand community to recount personal acts of devotion to the eBay site in its chat forums, and instances where they converted a friend or a loved one from the use of a competing site such as amazon.com.

In addition to these markers, an important characteristic of the brand community is the dynamics of the collectivity. Rather than being a static, stabilized state of social relations previously defined as a community, brand communities are dynamic and active. As a consequence, community members are neither passive, nor reactive individuals that only behave in accordance to internal forces, for example, compliance or self-esteem, or external forces, for example, group norms, or peer pressure, of the community. Members actively choose their community and decide when to leave it. Furthermore, ongoing interactions between and activities of community members shape and change the appearance and structure of the community itself. For example, how rituals and traditions are celebrated in the community influences the emergence of its cultural symbols. On the other hand, the brand communities' structure, its norms and set of rules, its rituals and traditions influence individual's future activities, social interaction, and consumption patterns. Overall, one can say that brand communities are not only "produced" by their members but also "reproduced" by social interactions between their members that reinforce the community. Thus, brand communities are dynamic social phenomena.

TYPES OF BRAND COMMUNITIES

In further understanding brand communities, it is important to distinguish between (i) brand communities that are comprised of consumer networks and those that consist primarily of small friendship groups and (ii) brand communities that are centrally managed by the firm's managers versus those that are often decentrally organized and managed through grassroots efforts by customer enthusiasts.

Network-based and small-group-based brand communities. In describing communities,

sociologists make the distinction between *neighborhood solidarities*, which they define as tightly bound, densely knit groups with strong relationships between members, and *social networks*, which are loosely bound, sparsely knit networks of members sharing weak and narrowly defined relationships with one another. Whereas neighborhood solidarities tend to be geographically conjoint, where each member knows everyone else and relies on them for a wide variety of social support, social networks are usually geographically dispersed groups that interact with one another for a specific reason, without prior planning.

Social psychologists similarly distinguish between *common bond* and *common identity* groups. Whereas the bond between members is the glue holding the group together in common bond groups, the attachment depends on identification to the whole group, in common identity groups. Common bond groups correspond to neighborhood solidarities and common identity groups to social networks. These distinctions, of viewing the community as either more or less the same small group of individuals with each of whom the consumer has relationships, or viewing it as a venue where numerous, dynamically changing people (strangers or acquaintances) with shared interests or goals meet, is useful in classifying brand communities.

In some instances, the consumer thinks of the brand community primarily as a venue, and only superficially associates it with any particular individual(s) within it. For instance, a consumer may log on to the bulletin-board of a software company because he/she has a problem that needs solving. In this case, his/her main interest is in solving the problem; there is no expectation or inclination to meet, chat, or socialize with any particular community member. Likewise, an engaged *yelp.com* or *amazon.com* consumer may read and benefit from reviews offered by others, without personal knowledge of, or relationships with, the reviewers. A brand community defined this way, that is, as "a network of relationships among consumers organized around a shared interest in the brand and promoted mainly via online channels, where intellectual and utilitarian support is primary and emotional

support is secondary” is a “*network-based brand community*.”

In other cases, the brand community’s member may identify primarily with a specific small group (or groups) of consumers, rather than with the venue in which the community meets. For example, a software developer may log on to the community chat-room specifically to chat with his/her geographically distant buddy group of kindred software developers every week to trade ideas, learn new concepts, and to socialize with them. Here, the developer’s focus is on communication with his/her peer group that he/she knows personally, rather than on the brand community venue. Such a brand community, “constituted by individuals with a dense web of relationships and a consciously shared social identity interacting together as a group, in order to accomplish a wider range of jointly conceived and held goals, to express mutual sentiments and commitments, and to maintain existing relationships,” is a “*small-group-based brand community*.”

Differences between network-based and small-group-based brand communities. There are several important differences between network-based and small-group-based brand communities. First, not surprisingly, the specific group with which the consumer interacts holds greater importance for members of small-group-based when compared to network-based brand communities. This is because the individual knows everyone else personally, and in many cases, may have shared histories and close personal relationships with them. As a result, relationships between community members are stronger, more resilient, and more stable than those in network-based brand communities, where members participate primarily to achieve functional goals (e.g., to trouble-shoot a problem) and have tenuous, short-lived, and easily severed ties.

Accentuating the group’s importance for small-group-based brand community members is also why the brand community venue is often only one of a number of places where such groups meet. Online social interactions are supplemented by face-to-face and other offline forms of interactions. For instance, a small group of HOG members may not only

chat online with one another periodically in the course of a week but also meet on weekdays for coffee and fellowship, and on weekends for group outings. In contrast, network-based community members are more likely to interact with each other exclusively through the brand community venue.

The two brand communities also differ in the range of activities its members engage in. Network-based community members are likely to engage primarily in narrow, instrumental, brand-related activities. In contrast, small-group-based community members engage in broad-based activities. For Harley riders belonging to small group brand communities, for example, social interactions occur through group rides for purely recreational purposes or for more formal goals such as fundraising (e.g., a rally for raising funds for the victims of an earthquake or a hurricane), competitions, political protests (e.g., anti-helmet law rallies), or community service. Even more frequently, small group members come together to meet at a pub or restaurant or to mutually examine the latest bikes and accessories at a nearby dealership.

These differences create what we call the *loyalty-influence paradox* in brand communities. Customers belonging to small-group-based brand communities are less likely to be loyal to a particular venue offered to them by the firm to interact in than members of network-based brand communities; yet, at the same time, small-group-based brand community members are more likely to be influenced by the social interactions with other members in the venue when they do participate than those belonging to network-based brand communities. Thus, loyalty to the brand community is inversely correlated with its influence on its members.

The distinctions between network-based and small-group-based brand communities also have implications for managers of these communities. Whereas the primary managerial objective in a network-based brand community is to match individual motives, for example, to find members willing to help solve product-related problems of those who have the questions, in the case of small-group-based brand communities, the main goal is to satisfy the motivations of group members to socialize

with one another by providing them various applications that facilitate social interactions. Thus, tools and applications such as buddy lists, instant messaging, providing status updates, and sharing of personal history are likely to be more valued in small-group-based brand communities. In contrast, applications that allow specific functional goals to be reached such as an archive of product-related problem solutions, an “ask-an-expert” service, and a reputation system which rewards problem-solving of other members, are more useful in network-based brand communities. The differences also mean that the marketers’ role is starkly different in the two cases: to be active information providers and problem solvers in the case of network-based brand communities, but to be more passive and indirect – in the background – in the case of small-group-based brand communities.

Firm-managed and customer-managed brand communities. In discussing the types of brand communities, another important distinction is between firm-managed and customer-managed brand communities. Many popular brands have many established brand communities, some organized and managed by the firm’s professional marketing managers, and others that are grassroots organizations founded and run independently by customer enthusiasts. For example, Microsoft XBOX 360, the leading video gaming console, has an established brand community (www.xbox.com/Community) hosted on Microsoft’s website and managed by Microsoft managers. Concurrently, there are dozens of XBOX brand communities, founded and managed by its fans such as the Brotherhood of the Box (www.bob.com.sg/forum) and Planetxbox360 (forums.planetxbox360.com).

There are several similarities between firm-managed and customer-managed brand communities. First, both communities are comprised of customers who are fans of the brand. Some participants may even have overlapping memberships within the two communities. Second, participants of both communities are interested in the same subject matter, namely news and information about the brand and its competitors. Finally, although consumers ultimately decide which community to join, there is at least some degree of targeting

by community managers. For instance, it is quite common to offer referral rewards in cash, kind, or recognition, to existing members to recruit friends, and to use direct marketing approaches such as email invitations to encourage selected customer segments to participate.

Differences between firm-managed and customer-managed brand communities. There are also several significant differences between firm-managed and customer-managed brand communities. Perhaps the most important distinction has to do with the community manager’s motives. Firms provide brand communities to their customers to accomplish marketing objectives. Some firms use brand communities to gather marketing research insights by monitoring discussions and/or interacting with participants. Others do so to increase participants’ loyalty to their products and brands, and to increase their purchase behaviors. Consequently, customers are recruited to join the community through targeted approaches, and the facilities and affordances provided to participants are designed to reach these objectives. It is not uncommon for firms to use established segmentation variables, in particular, demographic variables for recruiting community participants. This professional recruitment of fans into communities often contradicts with the social motives of the brand’s enthusiasts. This may be the reason why acquisitions and transformations of a customer-managed community into firm-managed communities often fail.

In contrast, customer-managed brand communities rarely have specific marketing goals. Instead, the community managers seek to express their love and admiration for the brand through organizing and managing the community. Participants, too, self-select and join the customer-managed brand community because of a shared passion for the brand, which often overlaps with common values, hobbies, and lifestyles. These differences indicate that customers in firm-managed brand communities should be more similar to each other in demographic characteristics, and those in customer-managed brand communities should be more likely to share psychographic commonalities.

The second difference between the two brand communities has to do with managers' constraints in the two cases. As noted earlier, professional managers of firm-managed brand communities are dictated by the firm's marketing objectives and therefore strive for consistency with its other marketing programs. Consequently, their emphasis is on a fit between the tone and content of the communications of the brand community members and the other marketing communications being sent by the firm. For example, a discussion in the brand community criticizing a newly introduced product and discussing its weaknesses will be viewed as inconsistent with the firm's ongoing advertising campaign that extols its virtues. Likewise, managers have an ingrained discomfort with giving customers free reign because of the possibility of unbridled and/or prolonged criticism by them regarding the firm. On the other hand, members of a customer-managed community do trust other members and their opinions more, because the firm's influence is not emergent. Practitioners and researchers are only now beginning to recognize and study these and other differences between firm-managed and customer-managed communities. This is one research area of great future potential, promising to increase our understanding of the scope and workings of brand communities.

CONSEQUENCES OF CONSUMER PARTICIPATION IN BRAND COMMUNITIES

Perhaps the most important reason for the success and growing importance of brand communities stems from the significant, multifaceted and long-lasting effects that participation in brand communities has on consumers. Consumer researchers have found that a key psychological process that occurs due to brand community participation is that the consumer psychologically identifies with the community, which in turn, mediates a number of important firm-relevant outcomes. It is useful, therefore, to understand what identification means, and examine its effects on the psychology and behavior of the brand community participants.

Identification with the brand community. Brand community identification captures the strength

of the consumer's relationship with the brand community, whereby the person construes himself or herself to be a member—that is, as “belonging” to the brand community. In contrast to other personal identities, which may render a person unique and separate, this is a shared or collective identity. The consumer's self-esteem is also boosted to the extent that his or her ego-ideal overlaps with that of the others, and acting as the other acts or wants one to act reinforces one's self-esteem. Identification resembles aspects of normative and informational influence, as well as referent power, and is characterized by the community member's social identity. Several studies suggest that social identity, defined in terms of a valued group, such as a brand community, involves cognitive, affective, and evaluative components.

Considering the cognitive component first, identification with the brand community involves categorization processes, whereby the consumer formulates and maintains a self-awareness of his or her membership within the community (e.g., “I see myself as part of the community”), emphasizing his or her perceived similarities with other community members and dissimilarities with nonmembers. The self is perceptually and behaviorally depersonalized in terms of the relevant group prototype. The cognitive component of identification captures the consciousness-of-kind aspect of brand communities.

Next, the affective component of identification implies a sense of emotional involvement with the group, which social psychologists have characterized as an affective commitment to the group and which can also be viewed as kinship between members. Organizational researchers have shown that affective identification influences in-group favoritism and citizenship behaviors toward the organization. Identification means that the consumer agrees (or strives to agree) with the community's norms, traditions, rituals, and objectives, and promotes its well-being. Third, the *evaluative component of social identity—group-based self-esteem*—has been defined as the positive or negative value connotation attached to brand community membership, and arises from evaluations of self-worth derived from membership. Group-based self-esteem

has been found to promote actions that produce in-group welfare by social psychologists.

Identification with the brand community is a useful psychological concept to understand consumer psychology in this context because it produces behavioral intentions to engage in brand community participation, and to maintain a positive self-defining relationship with other community members. It also produces a number of interesting and important outcomes. Among the consequences of identification with the brand community are brand relationship quality, learning, oppositional loyalty, and trust in the firm.

Brand relationship quality. Consumer research on brand community has shown that the consumers' integration within the brand community is a function of their relationships with the brand, other community members, the product, and the firm as a whole. Brand relationship quality is the customer's psychological attachment to the brand and its assessment as a satisfactory partner in an ongoing relationship, and is consistent with the idea that consumers frequently view brands, especially well-liked or beloved ones, in human terms, assigning animate characteristics to them. Brand relationship quality captures the extent to which the consumer identifies with the brand and views his or her self-image as close to or overlapping with the brand's image. It involves cognitive aspects such as the degree to which the consumer believes that the brand's image overlaps with his or her self-image, and emotional elements such as the degree of the consumer's emotional attachment to the brand.

Brand relationship quality and brand community identification share a bidirectional relationship with one another. For some consumers, the consumer's relationship with the brand precedes and contributes to his or her relationship with the brand community. Many consumers first discover and value the brand for the functional and symbolic benefits it provides. A harmonious relationship with the brand can lead consumers to seek out and interact with like-minded consumers who share their enthusiasm. Moreover, an existing identification with the brand facilitates integration and identification with the brand

community. For example, even when traditions, such as greeting other brand users, appear peculiar to the consumer, a strong relationship with the brand may help the person accept them and intrinsically endorse these practices.

On the other hand, integration with, and participation in the brand community, strengthens the customer's relationship with the brand. Not only does participation in the brand community provide opportunities for learning about the product and the brand associations (as we discuss below) but also close contact with other brand devotees rubs off on the consumer, increasing the strength of his or her emotional attachment to the brand. In today's environment, many marketers consider brand relationship quality to be the ultimate objective and metric of their marketing actions.

Learning. For complex, frequently evolving products, customers must continuously learn to keep abreast of changes and new developments and to take advantage of these advances. Traditionally, companies have been responsible for educating their customers to fully leverage the company's service offerings. They have done so by getting customers to participate in firm-organized training delivered by the firm's full-time or contracted employees. However, increasingly, many firms supplement this employee-based education model with peer-to-peer education delivered through brand communities, wherein customers assist their peers in learning about the products and their use. Customers thus take over service functions that are customarily performed by employees and act as "partial employees" of the firm. In eBay's Help Forums, for example, many novice sellers are interested in learning about the efficacy of different decision variables such as offering "buy-it-now" options, starting the auction with a low price versus a high price, and so on. Experienced sellers who are Forum members provide this service, bypassing the eBay employees.

The knowledge that a firm's customer possesses regarding its products, in particular, how to choose and use them, is a significant, valuable, and archivable resource, especially for complex products. Many brand communities exist to tap into, and they disseminate this

knowledge effectively to the participant base. For the individual member, this knowledge exchange translates into *learning*, which is defined as the customer's perceptions of increase in his or her own product expertise. Often, customers come to these communities for the first time because of the need to solve a specific problem. Once they receive the solution from the community, and hence have learned, they are captivated by the experience and become and stay a member themselves.

In brand communities, customers learn in vicarious and interactive ways, from the anecdotes, suggestions, and ideas of other members. The created knowledge is thus dependant on the members involved rather than on the pure truth. As members not only report short questions and/or manual-like answers but also share information on the situation, intentions, and feelings about an issue or action, they are able to convey the context. The context information contributes substantially to the learning experience, as it stimulates effective thinking, and supports information prioritization and interpretation. Additionally, in most brand communities, participants can access knowledge repositories such as records of prior conversations, product manuals, user guides, "hacks" from other members, and archives of (frequently asked questions (FAQs), that most communities store. The community site constitutes a knowledge base of all past incidents to aid the solutions of similar problems in the future and is therefore the collective memory of the individual interactions.

Oppositional brand loyalty. Prior consumer research has shown that brand communities strengthen a member's devotion and loyalty to the brand. For many loyal customers, the most important facet of this loyalty is derived from developing and expressing negative perceptions of competing brands. In fact, some researchers argue that this phenomenon of opposition to another brand and its community is the very defining feature of the brand community. *Oppositional brand loyalty*, which is defined here as "the participant's perception that competing brands are inferior to the target brand and should be avoided," benefits the firm by reducing the likelihood that members

will purchase competing brand products, strengthening the possibility of future purchases of the firm's brand.

For the brand community participant, the tendency to position the brand against the competition arises from the perception of being threatened, along with a desire for the target brand to maintain its superiority over the competition. Such an adversarial position is fostered by the perceived normative pressure to conform to the brand community's views and to signal this inclination to conform explicitly to the world, and to dissociate from the disfavored brands through means visible to the community.

Trust in firm. *Trust in the firm* is defined as "the brand community member's willingness to rely on the firm, stemming from a confidence in its benevolence, reliability, and integrity." Trust in the firm is important from a managerial standpoint not only because it creates a relationship that is highly valued by the customer, extending beyond the interactions with the brand community, but also because it has been linked directly to organizational performance.

Research has shown that trust in the firm is affected positively by community identification because the shared consciousness inherent in greater social identification supports stronger convictions about the firm's intentions and integrity, leading to greater trust in it. This reasoning is consistent with the influential commitment-trust marketing theory, which posits that shared values between partners positively affect their trust perceptions. Trust in the community's manager and governance structure also contributes to the brand community member's trust in the firm. This is because the beliefs in the benevolence, reliability, and integrity of the brand community manager, along with the discussions in the trusted community regarding the firm's products and brands, elevate the participant's beliefs in the good intentions and reliability about the firm, leading to greater trust in it.

CONCLUSION

Brand communities offer the promise of a marketing program that is synergistic with the

intrinsic motivations, interests, and empowerment of contemporary consumers. Widely applicable and increasingly used by mainstream consumers across a range of product and service categories, they represent avenues for marketers to generate a range of positive outcomes for the firm in cost-effective ways. For consumer researchers, brand communities are venues to study a host of psychological and social issues. Brand communities are certain to grow in research importance and practical significance in the coming years.

consumer neuroscience

Hilke Plassmann, Carolyn Yoon, Fred M. Feinberg, and Baba Shiv

BACKGROUND

The past decade has seen tremendous progress in academic research at the nexus of neuroscience, psychology, business, and economics. Even five years prior to that, fewer than a half-dozen papers appeared with keywords “neuroscience” and “decision making.” Presently, across these parent disciplines, the yearly count stands around 200, and is doubtless accelerating. The twin births of neuroeconomics and decision neuroscience has generated wide-ranging, ongoing debates on whether these hybrid fields benefit their parent disciplines and, within them, what forms these benefits might take (Shiv *et al.*, 2005). Their joint aim is to adapt tools and concepts from neuroscience – combined with theories, formal models, rich empirical data, and tested experimental designs from the decision sciences – to develop a neuropsychologically sound theory of how humans make decisions, one that can be applied to both the natural and social sciences.

A group of consumer psychologists is now dedicated to investigating consumer research questions with methodological and conceptual approaches from neuroscience. This emergent field, consumer neuroscience, is described in detail in this article. A primary, and critical, distinction is between “consumer neuroscience,” which refers to academic research at the intersection of neuroscience, psychology and marketing, and “neuromarketing,” which refers to practitioner and popular interest in neurophysiological tools – such as eye tracking, skin conductance, electroencephalography (EEG), and functional magnetic resonance imaging (fMRI) – to conduct company-specific market research. This article briefly details recent methods in neuroscience used by consumer researchers, presents basic ideas in consumer neuroscience as demonstrated by a variety of preliminary findings, and concludes with an outlook for the future of consumer neuroscience research.

METHODOLOGICAL APPROACHES IN NEUROSCIENCE

Many distinct methods are used in neuroscience to study neural processes underlying human behavior. Because each method has its own strengths and weaknesses, robust research findings typically arise from studies using several different techniques to shed light on the same question. A core defining precept is that neurophysiological methods measure responses of either the central or the peripheral nervous system. Most research in the nascent field of consumer neuroscience has availed of methods capturing changes, or manipulating activity, in the central nervous system, specifically, in the brain. However, physiological measures are hardly new to consumer research; even 30 years ago, researchers had measured skin conductance and eye movements to understand motivation and involvement in consumer behavior. Many peripheral physiological reactions can be readily measured, and used to make inferences about both neural functioning and correlated behavior. For example, pupil dilation is correlated with mental effort; blood pressure, skin conductance, and heart rate are correlated with anxiety, sexual arousal, mental concentration, and other motivational states; and emotional states can be reliably measured by coding facial expressions and recording movements of facial muscles.

Recent technological advances in measuring and manipulating brain activity allow us to observe in real time the neural processes underlying consumer decision making via functional brain imaging techniques. Most brain imaging research involves within-subjects comparisons of people performing different tasks; an “experimental” task (A) and a “control” task (B). The difference between changes in brain activity measured during A and B indicates parts of the brain that are differentially activated by A (this is often referred to as the “subtraction approach”). One of the oldest imaging methods, EEG, measures electrical activity on the brain’s surface using electrodes attached to the skull. EEG records timing of activity very precisely (resolution about 1 ms), but spatial resolution is poor, so that localizations when recording brain activity in subcortical areas that are small (e.g., the amygdala) can be problematic.

Positron emission topography (PET) is a newer technique that records positron emissions after a weakly radioactive blood injection. It does not measure brain activity directly, but rather metabolic changes linked to differentials in brain activity. PET offers better spatial resolution than EEG, but poorer temporal resolution and, because of rapid radioactive decay, it is limited to shorter tasks. However, PET usually requires averaging over fewer trials than fMRI, the method most widely used in consumer neuroscience. fMRI measures local changes in the ratio of oxygenated to deoxygenated hemoglobin. This ratio tracks neural activity because the brain effectively “overshoots” in providing oxygenated blood to active parts of the brain. Oxygenated blood has different magnetic properties than deoxygenated blood, giving rise to the signal picked up by fMRI (the so-called blood-oxygen-dependent-level, or BOLD, signal). Unfortunately, the signal-to-noise ratio of fMRI is, to date, fairly poor, so drawing tight inferences requires repeated sampling and many trials.

Yet another approach is single neuron recording, which tracks smaller scale neural activity (by contrast, fMRI measures activity of circuits consisting of thousands of neurons). In single neuron recordings, tiny electrodes are inserted into the brain, each measuring the firing of one specific neuron. Since these electrodes can damage neurons, the method is restricted to animal and special human populations, for therapeutic reasons (e.g., epileptic patients undergoing neurosurgery). Owing to its experimental use on animals, single neuron measurement has so far shed far more light on basic emotional and motivational processes than on higher-level ones, such as cognitive control. Regardless, the great body of extant research in neurobiology based on animal work (e.g., in rats and nonhuman primates) can directly inform theorizing in consumer neuroscience. Owing to functional and structural similarities in human and animal brains, the “animal model” has proved highly useful in the past, the main difference being a cortex enfolding the mammalian brain responsible for higher cognitive functions. Thus, owing to partial functional overlaps in subcortical areas, studying lower level processes, such as motivational signals during simple

decision making, is also informative for understanding human decision making. An advantage of animal work is the ability to perform manipulations (e.g., stimulation) to make causal inferences, and also to allow single neuron recordings as direct measures of neuronal activity, which are not possible with fMRI or PET.

The oldest neuroscientific approach applied to understand human decision making, and among the cornerstones in decision neuroscience, is studying patient populations with brain lesions. Localized brain damage, often produced by accidents and strokes, and patients who underwent radical neurosurgical procedures, are an especially rich source of insights. If patients with known damage to area X perform a particular task more poorly than “normal” patients, this suggests that area X may be vital in performing that task. “Virtual lesions” can also be created by transcranial magnetic stimulation (TMS), which creates temporary local disruption to brain regions using magnetic field stimulations.

CONCEPTS AND PRELIMINARY FINDINGS

Consumer neuroscience evolved alongside wide-ranging developments in behavioral decision-making research and cognitive neuroscience, with the common goal to better understand various elements of consumers’ evaluation and purchase decision processes (for a recent review, see Kenning and Plassmann, 2008). In consumer behavior research, neuroscience has received considerable attention for at least two reasons. First, neuroscience can be viewed as a new *methodological tool*, a “finer scalpel” to dissect decision-making processes without asking consumers directly for their thoughts, evaluations, or strategies. Second, neuroscience can be viewed as a source of *theory generation*, supplementing traditional ones from psychology and economics proper. Most of the remainder of this article is devoted to discussing these two perspectives.

Neuroscience as methodological tool. Methodological approaches in consumer research have tended to make heavy use of qualitative methods and survey measures to assess how experimental manipulations influence consumers’ attitudes and behavior. This has served the field

well, having led to a rich body of empirical data and cohesive theoretical foundations. When relying on stimulus–organism–response models from psychology, consumer researchers must, however, take certain “black-box” conceptualizations of brain processes on faith. This raises several caveats that neuroscience might help to address.

First, neuroscience measurements, though they may be intrinsically noisy, have a strong advantage over surveys and self-reports in regard to potential biases. Since neuroscientific methods measure brain activity and its correlates directly – rather than relying on what subjects tell us what they think of how they are thinking it – they may offer more reliable indices of certain variables important to consumer researchers. Consider research on emotions and their role in consumer decision making. Emotions play an important role in consumer research, but are notorious for being difficult to induce via clever experimental manipulation, owing to their partially unconscious nature and great response heterogeneity across subjects. Neuroscientific research suggests that we cleave the concept of emotion into two parts, emotional states that can be measured through physiological changes (such as autonomic and endocrine responses), and feelings, the subjective and largely ineffable experience of emotions (Bechara and Damasio, 2005). The emotional states themselves depend on basic (implicit) brain mechanisms, which are rarely available for conscious cognitive introspection. A similar division could well be made for motivational processes. Another general area where neuroscience may offer substantial measurement benefits concerns when consumers undertake rapid information processing (e.g., viewing a visually dense TV ad) or enacting speedy habitual choices (e.g., selecting which sort of eggs or milk to buy at the supermarket). For example, prior research that used steady state, visually evoked potentials (similar to EEG) to understand memory systems underlying ad recall found that changes in brain activity in certain frontal brain regions, while viewing TV ads, predict long-term memory for those ads. Habitual choices were investigated by Milosavljevic *et al.* (2009), whose subjects engaged in a fast perceptual choice task between very familiar food items, during which eye

positions were acquired with the help of an eye tracker. They found that subjects were able to make value-based choices (i.e., consistent with subjects’ preferences) within “a blink of an eye” (as fast as 400 ms).

Second, some preliminary consumer research uses brain imaging to *validate marketing scales*. A guiding principle is that brain imaging is too costly a tool to squander on large-scale surveys, but could be used to ask the “right” questions to get at the underlying (neuro)psychological phenomena. For example, a recent study by Dietvorst *et al.* (2009) used fMRI to investigate neural activity in brain regions associated with “theory-of-mind” abilities (i.e., MPFC, temporo-parietal junction, temporal pole) in salespeople, combining it with surveys and other traditional methodologies to develop a new scale for assessing salespeople’s interpersonal mentalizing skills.

Third, fortifying existing models of consumer decision-making with neuroscientific data may help them make *better predictions* about consumer behavior. An early effort in this direction is by Knutson *et al.* (2007), who combined neural and attitudinal measures to predict consumers’ purchases. The authors decomposed the purchasing process into three steps – (i) viewing a product, (ii) viewing product and price information, (iii) pressing buttons to indicate whether one wishes to buy the product at the end of the experiment – and investigated neural correlates of the preference formation stages (i, ii) and the price processing stage (ii). They found that product preference correlated positively with activity changes in, amongst other areas, the nucleus accumbens (NAcc), a region thought to be involved in reward prediction mechanisms, and that net value (WTP–price) correlated positively with activity changes in the medial prefrontal cortex (MPFC), anterior cingulate cortex (ACC), and frontopolar cortex. During the choice stage (iii), purchasing correlated negatively with activation in the bilateral insula, a region known to be involved in risk and pain processing, and positively with activity changes in the ventromedial prefrontal cortex (VMPFC), a region shown to encode preference signals at the time of choice. When distinguishing purchased-item trials from non-purchased-item

trials, the authors found significant differences in NAcc activation during preference formation, and both MPFC and insula deactivation during price processing, in line with their *a priori* hypotheses. They then estimated brain activity in these three regions of interests and entered them as covariates in a logistic regression, along with self-report measures of preference and net value, to predict subsequent purchasing decisions. Results indicated that the full model (i.e., including the neural measures) was a significantly better predictor than one including only self-report measures.

This idea has been further developed by recent work combining behavioral decision-making research with machine-learning algorithms used in computational neuroscience. Computational neuroscience attempts to understand mental processing so as to allow a computer to mimic the way the brain functions during these processes. It has been used extensively to model simple learning algorithms in humans, among other areas. A recent first attempt to follow this path in consumer neuroscience (Tusche and Haynes, 2009) investigated how implicit brain processes could predict hypothetical purchasing decisions using multivariate decoding. They found that activity changes in the insula and the MPFC – specifically, while one group of subjects was exposed to various cars and asked how much they liked each (referred to by the authors as a condition where attention was shifted to cars, but not to purchasing) and while another group of subjects was asked to respond to a fixation cross that sometimes was displayed on a car background (referred to as condition with neither attention to cars nor to purchasing) – predicted at the end of the experiment whether or not subjects wished to purchase the cars in question.

A similar approach using eye-tracking data as physiological measures, coupled with models from computational neuroscience of vision, has started to be applied in advertising research; extensions relying on additional neurophysiological measures and more detailed computational models have recently been suggested by Milosavljevic and colleagues (e.g., Milosavljevic *et al.*, 2009). Indeed, studies of which brain areas (and/or other physiological measures, such as eye movements) are involved

during certain tasks could well be enhanced by the use of machine-learning algorithms for predictive analysis.

Fourth, consumer researchers have begun to apply neuroscientific methods to test the abilities of *competing behavioral theories* to explain various phenomena. Although this has been the most common application of neuroscientific methods in consumer research to date, space limitations allow for only a few selected studies to be discussed. An early example is Yoon *et al.* (2006), who used fMRI to test whether semantic judgments about products and persons are processed similarly, finding that, contrary to several extant theories in marketing, they tend not to be. Specifically, when judgments of persons activated the MPFC, a region that in prior studies had been implicated in person processing, judgments of brands differentially activated the left inferior frontal cortex, an area known to be associated with object processing. Plassmann *et al.* (2008) used fMRI to study whether information that creates expectations about how good a product should taste (e.g., its price or brand) does so via postconsumption rationalizing or via changes in actual taste perceptions. The authors found the latter – that changing the prices of otherwise identical wines affected brain regions involved in interpreting taste pleasantness while the wines were being sampled. Hedgcock and Rao (2009) used fMRI to investigate different theories of how consumers make trade-offs between goods or services that differ on the utilities for single attribute, but whose overall utilities are similar, that is, are judged as equally good or bad across multiple dimensions. Prior research had confirmed that “asymmetric dominance” can lead to consistent violations of the regularity axiom: that introducing an alternative that is normatively irrelevant (because it is dominated by the existing alternatives) to the choice set can *increase* the choice probability of a nearby, dominating option. The authors found that activity patterns differed across conditions (e.g., higher in the dorsolateral part of the prefrontal cortex and the ACC vs higher in the amygdala, MPFC, and parietal lobule), supporting the existence of trade-off aversion.

Weber *et al.* (2009) investigated whether increased happiness, as opposed to alternative explanations consistent with rational choice

theory, can explain why consumers judge the value of money on the basis of actual amount of currency (nominal value) and not on the bundle of goods it can buy (real value), the so-called “money illusion.” The authors found that brain areas thought to be involved in the anticipation and experience of reward, namely the ventral medial portions of the prefrontal cortex (PFC), showed higher activity changes when subjects displayed the money illusion. These findings were interpreted to suggest that the money illusion is based on changes in reward- or happiness-related neural activity, and thus cannot be fully accounted for by standard “homo economicus” theories of rational choice.

Two other recent papers investigated the neural basis of the “endowment effect”: why we value goods we own more than (identical or equivalent) goods we do not. Vast theorizing has attended the endowment effect, ranging from a higher attraction to goods in one’s possession (possibly owing to familiarity, or overestimating positive and underestimating negative features) to an aversion of losing what one tangibly possesses. Knutson *et al.* (2008) compared situations where subjects sold various products, bought different products, and made purchasing decisions for yet other products, all while their brains were scanned using fMRI. They found that, in both the selling and buying conditions, product preferences correlated with activity changes in the striatum (more precisely, the NAcc), a region known to be involved in reward prediction. The authors found no difference in NAcc activity in the selling versus buying conditions during what they refer to as the “product preference formation stage” (i.e., the point when subjects were exposed to items and prices), evidence against the theory that owned goods are more attractive or “sticky.” In addition, the authors did not find activation in the insula (a region known to be involved in pain and risk processing, and so related to loss aversion) to correlate with product preference in selling versus buying trials. However, in “sell” trials specifically, individual differences in insula activity for preferred products *did* predict the extent to which subjects’ indifference points for selling differed from the mean indifference point of buying (referred to by the authors as “endowment effect estimates”). The authors

offer this as evidence of some role for insula activity, and thus for loss aversion as antecedent to the endowment effect. The second paper, De Martino *et al.* (2009), used fMRI to investigate the neural basis of within-subjects differences in WTA (willingness-to-accept)–WTP (willingness-to-pay) for lottery tickets, when subjects either owned (i.e., acted as seller) or did not own (i.e., acted as buyer of) the ticket. On a behavioral level, they found a systematic increase in the minimum selling prices, as compared to maximum buying prices, for a ticket with the same expected value. On a neural level, they found that the magnitude of WTP (in the buying condition) was encoded in the medial OFC (orbitofrontal cortex), and the magnitude of WTA (in the selling condition) in the lateral OFC. As the medial OFC has been found to encode increases and decreases in WTP during purchasing decisions across several fMRI studies (Plassmann *et al.*, 2007), and the lateral OFC was found to be responsive to the price (and thus the net value) of a good and to the anticipation of monetary losses, the authors suggest this finding as in line with the theory that, in the selling condition, transactions were perceived as potential losses. Interestingly, Knutson *et al.* (2008) found a partly overlapping area to be involved in the value comparison portion of the preference formation stage (i.e., only that time interval when subjects are exposed to the buying/selling price, a moment when subjects potentially started to think of their WTP/WTA in monetary units, rather than overall product preference, and compare it to the price, thus computing utility of the offer, i.e., whether or not it is a “good deal”). They found that the subjects showed increased activity changes in the VMPFC (among other areas) when they perceived the offer to be a good deal. However, it seems that the lateral part of the PFC did not react in the same way as in the study by De Martino *et al.* (2009), which could be owing to the fact De Martino *et al.* looked at neural correlates of within-subjects endowment effects, whereas Knutson *et al.* studied between-subject effects.

Of special note is that De Martino *et al.* (2009) also computed the difference between a “context-free” subjective value measure and a (either buying or selling) “context-biased”

one, and found the bilateral ventral striatum to correlate with increasing deviations from the unbiased value in the selling condition and decreasing deviations in the buying condition. The authors interpret this finding as evidence for the fact that the ventral striatum tracks the magnitude to which the subject's stated price deviated from the subject's true, unbiased value of the ticket in the selling and buying condition (i.e., reference dependent values) similar to a reward prediction error signal. Taken together, the findings of these two studies suggest that the endowment effect is related to negative emotional signals in the brain before and during the actual experience of endowment effects, supporting the loss aversion hypothesis consistent with prospect theory.

Neuroscience in Consumer Behavior Theory Generation. Consumer researchers have now begun to base hypotheses directly on *theories from neuroscience*. A recent example is Wadhwa *et al.* (2008), who investigated the impact of food sampling on subsequent consumer behavior, and compared two *a priori* hypotheses: the first – concordant with marketing practitioners, health experts, and much folk wisdom – that sampling a food will lead to lower subsequent consumption, and a second, rival hypothesis based on physiological theories of “reverse-alliesthesia,” that as drive states affect the incentive value of relevant rewarding stimuli, a consumption cue high in incentive value (such as sampling a food) can strengthen drive states like hunger and, thereby, lead to an increase in the urge to engage in reward-seeking behaviors (such as eating more, or increasing other consumption-related behaviors). A series of behavioral experiments support predictions arising from the notion of reverse-alliesthesia – sampling a food or beverage items high in incentive value can in fact make individuals more likely to engage in reward-seeking behaviors, independently from specific reward type. Specifically, sampling a drink high in incentive value (e.g., Hawaiian Punch) not only leads to increased consumption of other drinks (e.g., Pepsi), but also to consumers giving higher desirability ratings for hedonic food, hedonic nonfood, and on-sale items, compared with those who had not sampled the

high-incentive drink. Subsequent studies by the same authors investigate how motivational behavior impacts goal striving. In particular, they argue that if experiencing a hedonic cue enhances subsequent reward-seeking behaviors, then the induced motivational drive is also likely to enhance pursuit of a subsequent goal (defined as a representation of an internal state associated with a desirable outcome). For example, experiencing a hedonic cue (e.g., being exposed to romantic pictures) is likely to make one persist longer on a subsequently adopted intellectual goal of solving anagrams. Thus, unlike much of the extant research that has focused on how factors related to the goal state (e.g., desirability) can influence its pursuit, the focus here is on how factors *unrelated* to the goal state (e.g., incidental brief experiences with hedonic cues) can enhance subsequent goal pursuit. The authors' hypotheses are based on neuroscientific evidence (in rats and humans) of how the dopamine system works, that is, any hedonic cue that leads to enhanced dopamine activity could also motivate behaviors aimed in pursuit of a subsequently adopted goal associated with a desirable outcome.

Can cognitive neuroscience benefit from consumer research? Having detailed why consumer researchers are increasingly interested in joining forces with neuroscientists, let us briefly suggest how they might repay the debt, that is, “what's in it for neuroscientists?” In neuroscience, a number of developments led to a “cognitive revolution” that set the stage for the field of *cognitive neuroscience*, specifically. One major concern in early neuroscientific work was that it was largely descriptive in nature, and led to multiple isolated theories resistant to integration into a general, normative theory. An important advance came via the introduction of signal detection theory, a first attempt to relate neuronal activity directly to behavior in the field of vision science. We believe it is possible that sophisticated *formal models* from decision science and economics might help cognitive neuroscience establish a body of normative theory regarding how different types of decisions are enacted in the brain. A similar approach is currently used in so-called “model-based fMRI” studies, which investigate

neural correlates of decision-making variables by integrating models from economics and behavioral decision to aid in statistical data modeling.

Several pioneering neuroscientific studies on emotion and decision making were conducted using lesion patients, discovering impairments during simple economic decision-making tasks for patients with lesions specifically in the ventromedial portion of the PFC (for a review, see Bechara *et al.*, 2000). This represented something of a milestone for interdisciplinary work at the intersection of neuroscience, psychology and behavioral decision science, and stimulated a great deal of subsequent research. An opportunity for neuroscientists in this area is the possibility to combine the *wealth of empirical data* and *formal experimental design methods* from decades of work in behavioral decision science and studies on lesion patients. Although tasks have to be adapted to the specific requirements of patient work, experimental and empirical findings about observed behavior can be readily transferred to patient studies. This potential of behavioral decision research for neuroscience becomes slightly more complicated for brain imaging studies using fMRI, owing to the requirement for repeated measures. Nevertheless, behavioral protocols and empirical knowledge from behavioral decision science have greatly benefited the study of neural correlates of decision making. A prime example is a study of Plassmann *et al.* (2007) that used a design from behavioral economics, the Becker-de-Groot-Marchack auction, to sample trial-by-trial incentive compatible and nonhypothetical psychometric measures (here, economic preferences in the form of WTP bids) to correlate in real-time with repeated neurometric measures (here, changes in BOLD-signal). The authors found that activity in the medial orbitofrontal cortex and dorsolateral prefrontal cortex correlate with the magnitude of the subjects' WTP.

SUMMARY AND FUTURE DIRECTIONS

In this article we introduced the genesis, core concepts, and preliminary empirical findings of the nascent field of consumer neuroscience. The future of the field, and its eventual reception,

will depend on the insights and benefits it can generate in concert with its parent disciplines. We believe it will be crucial that researchers within the field of consumer neuroscience adopt a multimethod approach, including not only different neuroscientific tools but also traditional behavioral (laboratory) and field experiments, to transcend the limitations of mere correlational results subject to inverse inference and causation. Ideally, consumer neuroscience research will be able to link hypotheses about specific brain mechanisms (location, activation, direction, connectivity) to both unobservable intermediate variables (utilities, beliefs, goals, etc.) and observable behavior (such as choices), using a variety of different methodological approaches from neuroscience, statistical modeling, and social science proper.

Two emergent trends deserve special mention. First, computational, model-based consumer neuroscience studies will become increasingly crucial, as statistical approaches themselves become ever more sophisticated, from mapping functional connectivity to the use of multivariate statistics to decoding algorithms from computational neuroscience for predictive analysis. Second, a recent development of clear relevance to consumer neuroscience is the study of individual differences based on genetic information (often referred to as "imaging genetics"). Imaging genetics is the study of how genetic differences lead to individual differences in the morphology and functions of the brain, and thereby differences in behavior. The rapid proliferation of inexpensive, personalized genetic information should make such studies increasingly accessible and informative for consumer researchers.

The old saw goes that prediction is difficult, especially about the future. And so it is with consumer neuroscience, whose large time, financial, and learning-curve costs may appear to place it beyond the current reach of many consumer behavior researchers. We anticipate that the inevitable waning of these barriers over the coming decade will produce a flowering of interest in understanding the neural bases and correlates of consumer behavior, and encourage our fellow researchers to wade enthusiastically into this exciting, growing area of inquiry.

self-regulation

Kathleen D. Vohs and Ayelet Fishbach

People are not passive, listless automatons waiting for stimuli to demand a response. They plan, organize, prioritize, and modify their behavior. They set goals. Broadly, these behaviors are called *self-regulation*. Self-regulation is a vital process of the self. The self-regulation process not only sets goals but also monitors progress, shifts to new goals as necessary, and manages a hierarchically structured system of multiple goals.

The consumption setting is an ideal context in which to situate self-regulation theory and research. After humans evolved to form groups that led to the formation of culture, the development of trade and the emergence of humans as *homo economicus* brought about advances in reproduction and survival, not to mention quality of life (see CONSUMER WELL-BEING).

The role of consumption is still crucial today but not in the same way. The press to study self-regulation in contemporary settings comes in large part from the abundance of temptations and urges. “Having it now” interferes with long-term goal strivings, many of which are centered around consumption. Financial goals influence spending and health goals influence food intake (Herman and Polivy, 1975). It is difficult to understate the importance of self-regulation in humans ancestral history and now.

DEFINITIONS

Terms: Cognitive scientists use the construct of basic level to describe the default category used to define objects. In the current case, the basic level constructs are self-regulation and self-control. Many scholars use these terms interchangeably to mean modulation of an incipient response. Often the definition tacitly includes a secondary component that a more suitable response will be substituted for the undesirable response. Modulations of responses can involve suppression (the most common) or amplification. It can even mean creating a response out of nothing (e.g., faking a smile when opening a disappointing gift). When scholars use the terms

differently, they often take self-control to be the conscious form of response modification, whereas self-regulation can be nonconscious as well. At a broader level, some scholars have discussed self-management, which involves moving current goals up and down the priority list, the importance or salience of the goals often being determined situationally.

Scope: There are five general classes of responses that can be regulated. One can fixate one’s attention (e.g., when driving in a Minnesota snowstorm), down- or up-regulate emotions (e.g., stifling a laugh), overcome an impulse (e.g., to eat the whole bag of cookies), suppress intrusive thoughts (e.g., do not think about an ex-lover), or guide behavior (e.g., throwing a dart to hit the bull’s-eye). Eating, drinking, spending, sexuality, drug taking, avoiding exercise, and risky driving involve many or all of these foundational spheres of self-regulation and are but a few of the manifestations of self-regulation in a consumer culture.

Types: The current article cleaves the literature on self-regulation into two pieces: motivational versus social-cognitive inputs to self-regulation. It is no coincidence that one major distinction between types of self-regulation, namely controlled versus automatic processes, roughly corresponds to the degree to which they are energy-taxing (i.e., subject to motivation) and conscious. The automatic system guides behavior via well-learned (through practice or habit) or functional (i.e., evolutionary-based) action patterns. Owing to their ingrained nature, these responses are not said to take up energy or to be under conscious control. In contrast, consciously controlled processes cost energy to enact and involve a high degree of self-awareness. Hence, essential distinctions about broad types of self-regulation processes rest on the notion of motivation and cognition.

Process versus outcome: We emphasize the fact that self-regulation is a process, not an outcome. Too often, scholars conflate the process of attempting to reach a goal with the normative nature of the goal itself. Mostly people set goals that align with normative prescriptions for behavior, such as having

2 self-regulation

positive relationships with others, adopting healthy behaviors, and being morally good, but not always. People can engage in self-regulation in order to get themselves to overeat, binge drink, or engage in risky sex acts. More novel, insightful, and predictive research will come from separating the process of self-regulation from the outcomes that the actors intend to achieve.

OVERVIEW

As mentioned, the article reviews research on self-regulation as falling into one of two camps: energy or motivational versus social-cognitive. Whether a theory focuses on self-regulation from a motivational or cognitive perspective suggests that different inputs, processes, and outcomes are considered relevant in each approach. Admittedly, though, the dividing line between these two camps is artificial, if readers think that one theory or another could be in a different camp they may be right. We do not intend to draw exact dividing lines. Rather, parsing the research into motivational versus cognitive emphases is meant to be a loose classification system in order to highlight theories that share features.

MOTIVATIONAL INPUTS TO SELF-REGULATION

Motivation can loosely be defined as effort or energy that one puts toward a goal (*see* MOTIVATION AND GOALS). Freud's psycho-dynamic model has been the energy model with the greatest impact on the psychology of self-change. As the reader is probably noting already, that model has long since dominated scientific studies. Baumeister, a social psychologist who studies self-regulation, once quipped that, "energy models are so out of fashion that we [i.e., social scientists] aren't even against them anymore" (personal communication, March 16, 2004). Today's motivation research, while certainly not Freudian in nature, embraces energy as a central component that reorients behavior away from entrained routes and toward desired ends.

Cybernetic models. Cybernetic models describe the process of self-regulation as discrepancy-closing. When a person identifies a desired end

state, the motivational system calculates the size of the discrepancy between the present state and the desired state and guides action toward closing the gap. The acronym "TOTE", which stands for Test, Operate, Test, Exit, is often used to denote this process. According to this notion, once the person identifies a desired end state, the required effort to reach this state is assessed (Test), which leads people to put effort into achieving it (Operate), which requires another assessment of the distance (Test), which cycles around recursively until the process ends because the end state is achieved (Exit). For example, a woman may perceive she needs to go on a diet. She calculates how much weight to lose, trims calories and exercises, and steps on the scale from time to time. She stops dieting when the gap is closed either because she reached her goal (success) or altered it (likely due to repeated failed attempts).

Research by Carver and Scheier (1990) developed this feedback model into a comprehensive model of feedback loops. Their model highlights emotions as feedback for self-regulation. Positive emotions signal that the rate of closing the gap to goal attainment is faster than expected. In this case, people reduce their effort or "coast." Negative emotions, conversely, signal that the rate of closing the gap is slower than intended. In this case, people increase their effort investment. An interesting implication of this model is that people will work harder toward a goal when they feel bad about it than when they feel good about it.

Limited-resource model of self-regulation. A recent model depicts self-regulation as being a function of a limited stock of energy. This energy is said to be involved in every act of self-regulation, which implies that it is easily taxed. When people are low in self-regulatory resources, they are said to be in a state of depletion (or ego depletion), which portends poor self-regulation subsequently. At last count, over 120 published experiments have shown the pattern that was predicted by the limited-resource model: after a person engages in self-regulation, ensuing attempts at self-regulation are less successful than if the person had not earlier engaged in self-regulation. The resource is renewable but unfortunately it

does not seem to replenish itself with as much ease as it gets depleted.

The first papers on the limited-resource model established basic self-regulation findings (Baumeister *et al.*, 1998). In this work, participants would engage in one form of self-regulation (or not, for the neutral conditions) and then all participants would be tested in a different domain of self-regulation. Papers subsequent to those focused on boundary conditions of the model or mechanisms. Particularly germane to the current volume is work on breaking one's diet and impulsive spending as a function of self-regulatory resource depletion and decision making impacting self-regulation (*see IMPULSIVE AND COMPULSIVE BUYING*).

Controlling caloric intake is a perennial self-regulation problem and one that is especially interesting given that people cannot completely exit the eating cycle. That is, when studying other overconsumption problems, such as drug or nicotine addiction, one solution is to simply not consume the substance. This does not work with food intake. Hence, how people grapple with regulating eating is of special interest because people must indeed constantly regulate.

The limited-resource model was used to show that dieters, but not non-dieters, eat more when they have been taxed of their self-regulatory resources (Vohs and Heatherton, 2000). In a representative experiment, for instance, dieters and non-dieters were brought to the laboratory individually and were first asked to watch a boring movie about bighorn sheep. There were also snacks in the room that were either nearby the participant's chair or far away, and those snacks were either labeled as "off-limits" or "for the taking." Being bored made it likely, we thought, that participants would want to eat the snacks, but we knew from prior research that dieters may well be tempted but would not eat the snacks because they were fattening (chocolate candies, cookies, etc). In fact, we hypothesized that the greatest temptation would be for the participants for whom the snacks were nearby and allowed to be eaten. In this condition, not eating the goodies would require the most self-regulation. For dieters, we surmised that if they were reduced in the amount of self-regulatory resources they had, then later

if we surprised them with another context in which they had to taste food (a taste-and-rate ice cream task), they would not be able to exert enough resources to curb their desire to indulge. We observed the expected pattern. As predicted, dieters who sat next to candies and were allowed to eat them—but held back because of their personal dieting goal—later ate the most ice cream during a ratings task. Non-dieters are not regulating in the domain of food intake, so their eating—in the initial phase and the ice cream eating test phase—is merely a function of internal cues and not because of depletion. This article raises a broad point about the limited-resource model of self-regulation and motivation: when people become depleted, they will not behave impulsively at random. What will come unglued is that which they are regulating the most: for dieters, this means that they should eat more when depleted, which are the findings of Vohs and Heatherton (2000). For consumers trying to curb their spending, this would mean purchasing. Vohs and Faber (2007) found exactly this pattern.

The studies testing impulsive spending as a result of self-regulatory resource depletion (*see IMPULSIVE AND COMPULSIVE BUYING*) are similar to the aforementioned studies on eating among dieters with one key difference. We argued in this article (Vohs and Faber, 2007) that everyone has an outside goal of reigning in spending (*see CONSUMER MATERIALISM*). In almost all situations, some self-control in buying is necessary in order to achieve other goals. People who think they have unlimited funds, such as celebrities, may soon discover that their funds have run dry (e.g., Mike Tyson's bankruptcy, Michael Jackson's debts). Hence, we claimed that most people have at least an implicit goal not to spend impulsively. This generalization meant that we expected to see unplanned spending (as a form of lax self-regulation) as a consequence of self-regulatory resource depletion as a main effect. Above and beyond this main effect, we also predicted that the buying behavior of people who are regulating in the domain of spending would be especially affected by resource depletion. As predicted, our experiments revealed that depletion condition and interaction of depletion condition with trait impulsive buying tendencies

are major causes of impromptu spending. One representative experiment had participants in the ego depletion condition list out their thoughts for several minutes, with the exception that they were not allowed to think thoughts of a white bear. Other participants were allowed to think anything they wanted for the thought listing task, including a white bear. Hence, the former group has a thought suppression goal, whereas the latter does not. After the thought listing task, participants were shown 22 products that were said to be under consideration for inclusion in the university bookstore. We gave them \$10 to spend in the mock bookstore or take home. The dependent measure was ad hoc spending in this spontaneous purchasing situation. As expected, participants who had been in the thought suppression condition spent more money and bought more items than participants in the no suppression condition. Moreover, participants who had chronic problems with overspending spent more than other participants when they had been depleted of their self-regulation resources. In short, controlling one's spending uses self-regulation, and when self-regulatory resources run low, unplanned and unnecessary spending is likely to occur.

The third domain that is especially relevant to the notion of consumer self-regulation is how choice influences self-regulation. The executive function of the self houses both self-regulation and decision making. As a consequence, making choices and controlling the self are likely to be interrelated (*see* CONSUMER DECISION MAKING). We posited that making choices would tax the self-regulation system in a manner similar to when people engage in self-regulation. That is, we predicted that self-regulatory abilities would be compromised after making choices. Eight studies supported this hypothesis (Vohs *et al.*, 2008).

In one study, participants in the choice condition (comprised primarily of first-year college students) were asked to select courses that they would take for their remaining years in college, whereas those in the no-choice condition simply reviewed the course catalog. Next, all participants were given time to study for an upcoming test purportedly to measure participants' intelligence. Participants in the choice condition practiced less (that is, procrastinated more) than

those in the no-choice condition. In another experiment, participants in the choice condition were asked to make a series of binary choices between consumer products, such as a yellow candle versus white candle. Participants in the no-choice condition rated the same products on how often they had used such products but did not make choices. Then all participants were asked to keep their forearms in painfully cold water for as long as possible. As predicted, high choice participants were less able to endure the pain of cold water than no-choice participants. In a study that took place at a shopping mall, shoppers reported the extent they had made decisions during the day, including how many decisions, how much they deliberated and how personally responsible they felt for the decisions, which formed a latent variable that we called investment in choices. Later, shoppers were asked to complete arithmetic problems. The more choices shoppers reported having made, the fewer math problems they attempted, the less time they spent on them, and the more problems they got wrong.

Follow-up studies found that when people are depleted of their self-regulatory resources, they are more likely to buy hedonic products more than utilitarian products. These studies also confirmed the linkages between self-regulation and choice in a non-North American context (Western Europe), which is important because one would want to know that these effects occur outside of the United States and its plethora of choices. In sum, these studies suggest that the processes involved in decision making rest on the same mechanism that is used for self-regulation, which unfortunately exact significant intrapsychic costs.

OTHER MOTIVATIONAL INPUTS

Motivation has much to do with whether the actor thinks that he or she is capable of reaching the goal. One consumer model of goal attainment (Bagozzi and Dholakia, 1999) focuses on self-efficacy, which is the belief that a person can achieve what he or she wants to achieve. Self-efficacy is a construct somewhere between self-esteem (one's appraisal of oneself in terms of goodness or badness) and self-regulation (goal attainment) in that it involves self-perceptions

of ability. Having the sense that one can meet valued goals is crucial to self-regulation success because it amps up the motivation to do so.

A small but growing literature on lay beliefs about the structure of self-regulation also points to the role of motivation. At a broad level, personal theories of self-regulation as a flexible, dynamic system has been found to benefit self-regulation.

Social Cognitive Inputs to Self-Regulation

Social cognitive models vary by whether they address the regulation of a single versus multiple goals. In addition, models that address regulation of multiple goals vary by whether they address goals that are of equal status (e.g., goals related to career and family) versus goals that pose a self-control dilemma (e.g., eating healthy and tasty). We offer a brief overview of some of the more prominent models in this domain.

Regulatory focus theory. Other research distinguishes between the different types of goals that individuals pursue and how they may evoke different processes of self-regulation. The most basic distinction exists between the goal to obtain pleasure versus avoid pain. For example, every organism strives to get food as well as avoid danger (and stay alive). On the basis of this distinction, regulatory focus theory distinguishes self-regulation with a promotion focus, on the presence and absence of positive outcomes or gains, and self-regulation with a prevention focus, on the presence or absence of negative outcomes or losses. Individuals strive toward positive outcomes when pursuing advancement needs and aspirations (e.g., planning a vacation). They further strive to avoid negative outcomes when pursuing security needs and responsibilities (e.g., getting a fire alarm). Interestingly for many goals (e.g., personal hygiene), both frames are possible and individual differences as well as situational factors will determine which focus a person adopts.

According to regulatory focus theory, different processes characterize the different foci and they have different psychological consequences. In particular, the pursuit of promotion goals is oriented toward receiving gains, whereas the pursuit of prevention goals is oriented

toward non-losses. The emotional consequences of pursuing promotion goals further differ from those of prevention goals. For promotion goals, successful pursuit results in happiness and failure results in sadness, because these emotions characterize the presence versus absence of gains. In contrast, for prevention goals, successful pursuit results in calmness and failure results in anxiety, because these emotions characterize the absence versus presence of losses. In addition, research finds that people enjoy pursuing a goal in a manner that sustains their regulatory focus, a phenomenon titled “regulatory fit” (Higgins, 2000). In particular, people prefer to use eager strategies toward promotion goals and vigilant strategies toward prevention goals.

Goal systems theory. Whereas the basic unit of research on self-regulation involves the pursuit of a single goal, people rarely hold only one goal at a time. Rather, they often need to juggle between several goals that compete with each other for resources (e.g., buying a house versus increase contribution to retirement) or that directly undermine each other (e.g., eating healthy and fatty food). Research on goal systems theory addresses the cognitive operations that govern the regulation of multiple goals. According to this research, goals are organized in associative networks, connecting higher order goals with lower level means of attainment. Each goal is associatively linked to several attainment means. Similarly, each means is connected to several goals that it can potentially serve. For example, the goal of having a good figure may be connected with the means of eating healthy food and exercising, and the means of exercising may be connected with goals of having a good figure and leading a healthy lifestyle. In addition, there are inhibitory links between unrelated goals or between unrelated means that potentially compete for resources.

There are several predictions that follow from this theory. For example, it assumes that the presence of potential means to a goal activates the corresponding goal, such that individuals will adhere to the goal upon encountering a means (or an opportunity) for goal pursuit. For example, the mindless impact of an advertisement on

consumer choice may reflect such goal activation upon encountering cues for means of attainment. In addition, because competing goals inhibit each other, a focal goal can often lead to the inhibition of another alternative goal. In this way, the focal goal “*shields*” itself from alternative ones by directly reducing their accessibility (Shah, Friedman, and Kruglanski, 2002). Empirically, this inhibition is often reflected in the slowing down of lexical decision times to concepts that represent alternative goals. For example, activation of academic goals slowed down the lexical decision time to concepts related to alternative goals (e.g., exercising).

Other research on goal systems documents a desire for multiple goal attainment. Given the presence of several salient goals and limited motivational resources, individuals search for attainment means that are linked to the attainment of several goals simultaneously. For example, a person may prefer to dine out (vs. dine in) in order to satisfy both hunger and various social motives (to see and be seen, etc.), or commuters may choose to commute by bike (vs. car) in order to save money and keep in shape. Interestingly, however, as the number of goals attached to a given means increases, each association becomes weaker. The result is a dilution of the means–goal association, which may reduce the perceived effectiveness of the means with respect to the goal. That is, although individuals often seek means that are linked to multiple goals, they also find them less effective than those which serve fewer goals. In a demonstration of this *dilution effect*, Zhang, Fishbach, and Kruglanski (2007) found that when participants considered the different goals (e.g., building muscles and losing weight) that a single means (e.g., working out) could satisfy, an increase in the number of goals resulted in a reduction in the perception of the instrumentality of the means with respect to each goal. As a result, individuals sometimes choose means that are connected with fewer goals, because they believe these means are more effective. For example, participants in a study were less likely to use the writing function of a pen that had also been used as a laser pointer (vs. was not used as a laser pointer) when they only needed to write. It appears that the general preference for means that serve several goals

diminishes and even reverses when a person focuses upon pursuit of a single goal.

DYNAMICS OF SELF-REGULATION

When individuals wish to successfully pursue several goals, they often take into account a sequence of actions that unfold over time. Then, completed actions in the past or upcoming actions in the future can both influence which goal an individual attends to in the present. In addition, missing actions in the past or the absence of plans to pursue a goal in the future will influence the decision to pursue a goal in the present.

Research on the dynamics of self-regulation (Fishbach and Dhar, 2005) attests that self-regulation follows a sequence of actions that either balances between several goals or highlights the pursuit of one, focal goal. According to this research, whether people balance or highlight depends on whether they represent actions that pursue a goal as an expression of their commitment to this goal or as a signal that progress was made. When actions express commitment, each action increases goal commitment and goal adherence, and hence people highlight the goal. However, when actions signal progress on a goal, each action decreases the perceived need for taking more actions, and hence people balance between their goal pursuits.

One factor that determines whether people represent goal actions as an expression of their commitment or as making progress is their degree of commitment certainty. When individuals are not sure whether the goal is valuable for them, they highlight by adhering more to a goal if they have done so before. But when individuals are already sure that the goal is valuable, they wish to monitor their level of progress and they adhere to a goal more if they have not done so since they perceive greater need to make progress. For example, shoppers who were buying luxuries, expressed greater interest to use a frequent buyer card that had a visual emphasis on completed purchases (using stamps) than on missing purchases (using punches), because completed purchases signaled that buying luxuries is valuable and promoted highlighting of the purchase behavior. In contrast, shoppers who were buying necessities were more likely

to use a frequent buyer card if it emphasized missing (vs. completed) purchases, because missing purchases signal need for progress and promote balancing for the absence of purchases.

These findings have implications for pursuing group goals, when individuals join force with other group members, for example, when contributing to a charity. Research finds that first time donors are more likely to contribute if they receive information on accumulated contributions to date (vs. missing contributions to go), whereas returning donors are more likely to contribute if they receive information on missing contributions to go (vs. accumulated to date). The reason is that first time donors wish to evaluate whether the charity goal is valuable and their behaviors follows, or “highlights” others’ contributions. Returning donors wish to evaluate the rate of progress on the charity goal and their behavior compensates or “balances” for others’ contributions.

The arrangement of action alternatives also influences the dynamic of self-regulation individuals follow. Individuals often make selections from sets that include items that serve multiple goals. For example, they browse a television guide that includes educational shows and light sitcoms, or they go through highbrow news magazines and lowbrow fashion magazines on a newsstand. The arrangements of the alternatives influences people’s perceptions of them as competing against versus complementing each other, which in turn influences the dynamics of self-regulation they would follow. In particular, separating items into two sets (e.g., two bowls), versus presenting them together in one set (e.g., one bowl), determines whether individuals perceive the items as conflicting versus complementary. When the items are presented apart, they seem conflicting and promote a highlighting dynamic of choice; when the items are together, they seem complementary and promote a balancing dynamic of choice.

These dynamics have unique consequences for situations in which the items on a set pose a self-control conflict. When goal and temptation alternatives (e.g., healthy and unhealthy foods) are presented apart from each other, they seem to compete against each other. As a result, people are more likely to resolve the conflict in favor of

the goal alternatives in a dynamic of highlighting: they assign a greater value to goal alternatives (e.g., educational shows, news magazines) than to tempting alternatives and consistently choose goal alternatives for both immediate and future consumption. In contrast, when choice alternatives appear together and seem to complement each other, thus promoting balancing, people tend to resolve the self-control conflict in favor of the immediately gratifying temptation option. As a result, they value the tempting alternatives (e.g., watching sitcoms, reading lowbrow fashion magazines) more than the goal alternatives and prefer these tempting alternatives for immediate consumption, thereby postponing the consumption of goal alternatives to a future occasion. The reason tempting alternatives are selected first in this presentation format is that their value is immediate, whereas the value of the goal alternatives, although larger, is delayed. Thus, in a self-control conflict, a balancing dynamic would most often take the form of “first temptation then goal” rather than “first goal then temptation.”

Counteractive control theory. Other cognitive models address the exercise of self-control and overcoming temptations. In particular, counteractive control theory (Fishbach and Trope, 2007) examines the processes of resolving goal conflict between an important long-term goal and a momentary temptation (e.g., saving and spending, eating healthy and enjoying fatty food, study and leisure). According to this theory, the process of counteracting temptations involves asymmetric shifts in motivational strength, namely an increase in the motivation to pursue a goal and a reduction in the motivation to pursue temptations. Such asymmetric shifts are often of conscious, deliberative nature, but they may involve nonconscious, implicit strategies that promote individuals’ long-term interest without requiring conscious awareness. In addition, some strategies are behavioral and they act on the choice opportunities themselves (e.g., increasing the availability of goal items) while other strategies are more cognitive by nature, and they act on the representation of the choice opportunities (e.g., increasing the value of goal items).

Individuals employ behavioral counteractive strategies when they choose, for example, to

make rewards contingent on undergoing uncomfortable (but helpful) medical tests and make penalties contingent on failing to do so. Using this strategy, they counteract the temptation to avoid the test. Another behavioral strategy involves precommitment to pursue goals and avoid temptations. For example, while grocery shopping, a consumer might suspect that having tempting sweets available in the kitchen will pose a problem and decide to purchase fruits instead. People further avoid temptations by maintaining physical distance from tempting objects, while ensuring proximity to objects associated with goals. For example, they will push away the liquor glass and pull toward them a glass of water, in order to stop drinking.

Other cognitive strategies alter the representation of goals and temptations. Thus, individuals often counteractively bolster their evaluations of goals and dampen their evaluations of temptation. For example, health-conscious individuals who were facing a choice between health bars and unhealthy chocolates evaluated the chocolates as less appealing than the health bars before choosing between the two, in order to secure making the "right choice." Individuals further promote goal pursuit by adopting a concrete representation of goals but an abstract representation of temptations, because the more concrete representation facilitates action. For example, in a study on the regulation of academic goals, students formed concrete behavioral plans to facilitate pursuit of their academic goals (Gollwitzer and Brandstätter, 1997). In another study on delay of gratification, children resisted the temptation to eat a marshmallow by thinking about it as an abstract cloud, thus cooling its appetitive influence (Mischel, Shoda, and Rodriguez, 1989).

Finally, similar patterns of asymmetric shifts exist for individuals' nonconscious self-control operations. For example, they nonconsciously boost the value of the goal while dampening the value of the temptation. In addition, implicit counteractive control entails changes in the accessibility of goals and temptations. Individuals shore up their goals by activating goal-related constructs in response to interfering temptations and by inhibiting temptation-related constructs in response to goal-related cues. For example, a study on

college students demonstrated that subliminally presenting the word "television" reduced the time students took to subsequently recognize the goal-related word "study" (goal-related), and similarly presenting the word "study" increased the time students took to subsequently recognize the word "television" (Fishbach, Friedman, and Kruglanski, 2003).

CONCLUSIONS

The research reviewed in this article is aimed at offering two broad perspectives on self-regulation. One is motivational, the other cognitive. For the former, energy models are increasingly popular. Future work could, however, expand on the link between emotion and motivation as these two often interact in novel ways (e.g., urges and impulses as emotions; see CONSUMER DESIRE).

We encourage researchers to remember that self-regulation is a process, not an outcome. While it is true that most self-regulation acts are aimed at securing goals that will lead to normatively better, longer, and morally right lives, some do not. An emphasis on the process rather than the outcome will open new vantage points.

Problems because of failures of self-regulation seem to be taking over the Western (and, increasingly, Eastern) world. Drug and alcohol abuse, overeating, sexual improprieties, underachievement, insufficient exercise, Internet and video game addictions, violence, and crime are all linked through problems with self-regulation. Indeed, it is difficult to think of many behavioral problems that do not have a regulatory component. Against this backdrop, it is somewhat consoling that along with problems of self-regulation comes an increasing emphasis on the importance of research in this area.

consumer information processing

Hélène Deval and Frank R. Kardes

Marketing researchers and marketing managers spend enormous resources on monitoring, predicting, understanding, and influencing the behavior of consumers. This requires investigating the effects of marketing communications at each stage of consumer information processing: attention, comprehension, evaluation, memory, and choice (Wyer, 2008). Consumers can use virtually any type of cue, attribute, or knowledge as information, and this information is processed sequentially to facilitate judgment and decision making.

ATTENTION

Consumers are limited information processors (Kardes *et al.*, 2011). They often lack the motivation, capacity, or opportunity to analyze the judgmental implications of all relevant pieces of information. It is therefore critically important to capture their attention and interest. Specific goals influence the amount of processing and lead consumers to focus selectively on certain products or services. A given product or service is valued more heavily when it is goal relevant (valuation effect) and consumers tend to ignore goal-irrelevant products (devaluation effect, Markman and Brendl, 2005). The devaluation effect is typically much larger than the valuation effect. For example, even money is devaluated when hunger, thirst, or some other need is highly salient, even if money could indirectly help satiate that need.

Regardless of their relevance to a specific goal, some stimuli are conspicuous and therefore capture attention automatically (Kardes, 1994). Specifically, salient and vivid stimuli are highly noticeable and difficult to ignore. The vividness of a stimulus depends on the properties of the stimulus itself. It is determined by concreteness, emotional interest, and psychological proximity, independent of the context or background (e.g., the color red is a vivid color). Salience is determined by a difference in the background—contextually novel, unexpected, complex, or moving stimuli stick out

(e.g., a red package surrounded by gray packages on a shelf is salient but the same package becomes nonsalient if surrounded by other red packages). Not surprisingly, advertisers are well aware of the importance of capturing the attention of consumers and so constantly try to create novel and salient ads that capture consumers' attention and interest. For example, ads that have a surprise element, such as mystery ads that hide the identity of the product till the end of the ad, are attention drawing (Kardes *et al.*, 2011). For unfamiliar brands, mystery ads help build a strong category-brand association in memory because withholding the identity of a brand arouses curiosity. This strong category-brand association results in the activation of a brand whenever the product category is brought to mind. Similarly, ads that use multiple variations on a theme, and ads that use upward camera angles are contextually salient and capture interest. In the same way, unusual packages, such as cylinders for Pringle's potato chips, plastic eggs for L'eggs panty hose, and 15-packs for Strohs beer, are salient and attention drawing. Salience effects are reduced when involvement or motivation for accuracy is high (Kardes *et al.*, 2011).

COMPREHENSION

Comprehension is the ability to interpret and assign meaning to information by relating it to knowledge already stored in memory (Wyer, 2008). It involves the formation of inferences that enable consumers to grasp the meaning of a product claim without systematically considering and evaluating each possible meaning of each word presented in the message (Kardes *et al.*, 2008). For example, instrumental inferences (the statement "he pounded a nail into the wall" implies that a hammer was used) facilitate communication. Interpretive inferences usually involve very little effort, making it difficult for the consumer to discriminate between the information that was actually presented and interpretive inferences based on this information (Kardes, 1994).

Prior knowledge leads to selective processing of knowledge-consistent information. Take two people that have opposite opinions about computers—one is a PC user and the other

2 consumer information processing

is a Mac user. It is likely that the PC will perform better on some dimensions (e.g., it is cheaper) and the Mac will perform better on other dimensions (e.g., it is more reliable). Both computer users will use prior knowledge and will selectively process the information that supports their original opinion, and, consequently, the same message will be interpreted in different ways by different consumers.

Similarly, most consumers assume that price and quality are highly correlated, and this assumption leads consumers to focus on information that is consistent with this hypothesis (Kardes *et al.*, 2008; Posavac *et al.*, 2005). Consequently, recognition and recall performance is better for high-price/high-quality brands and low-price/low-quality brands than for brands that do not confirm the original hypothesis. This leads to overestimation of the strength of the relation between price and quality. This overestimation increases the willingness of consumers to spend. Overestimation is reduced only when selective processing is discouraged owing to low cognitive load, random information presentation, or a low need for cognitive closure. The need for cognitive closure refers to a preference for a definite answer to a judgmental problem, any answer rather than ambiguity, inconsistency, or confusion (Kruglanski and Webster, 1996). Selective processing, anchoring, priming, primacy, heuristic reasoning, and stereotyping effects decrease as the need for cognitive closure decreases.

When processing effort is low, consumers are more prone to the effect of misleading advertisements using claims that are literally true but figuratively false. The claim “Brand X may help whiten your teeth” is literally true: the product may or may not help whiten your teeth. Yet, because in everyday language *may* is interpreted as *usually*, the claim is figuratively false. Likewise, consumers are prone to infer that the claim “Women who look younger use Oil of Olay” indicates that “Women who use Oil of Olay look younger” (Kardes, 1994). This is known as “confusion of the inverse,” which occurs frequently in everyday reasoning.

Low processing effort also results in other types of biases, like the truth effect (Kardes, 1994). The perceived validity of a statement

increases with mere repetition independently of its objective validity. Because consumers might be unwilling or unable to judge the validity of a statement directly, they use other cues such as familiarity to assess the validity of a product claim. If people feel that they have heard the claim before, they assume that the claim is probably true even if they cannot remember where they heard it in the first place. The truth effect leverages this relation between familiarity and perceived validity: repetition increases familiarity, and in turn, familiarity increases perceived validity. The truth effect has obvious implications with respect to the effects of repetitive advertising on the perceived validity of product claims. This effect is less pronounced when processing is high because consumers are more likely to recognize that the impression of familiarity is because of repetition.

EVALUATION

After a product has captured consumer attention and interest, and after the information about the product has been understood, consumers assign a value to it in order to determine how much a product is worth to them (*see* ATTITUDES; PERSUASION). Selective processing leads consumers to focus on positive aspects of positively evaluated products and negative aspects of negatively evaluated products (Kardes *et al.*, 2011). Returning to our example of the PC user and the Mac user, selective processing has implications for the evaluation of products. The Mac user evaluates Macintosh computers positively and PCs negatively. He will therefore focus on the positive aspects of a Mac. Conversely, he will focus on negative aspects of a PC.

Selective processing can also induce product attribute information distortion. In this case, the information that does not support an initial preference is not ignored but its value is simply discounted while the importance of information supporting the initial preference is enhanced. When more than one product is present and consumers are encouraged to identify the product that is the leader, one alternative becomes the focal alternative. When consumers begin to prefer tentatively one alternative over others, the attributes of the

focal alternative are rated as more important or as more favorable, relative to attribute ratings assessed in a pretest or a control group. One piece of information that would otherwise be interpreted as neutral might be interpreted as supportive of the leader. Information distortion can amplify the pioneering brand advantage or increase preference for an inferior alternative when attribute information is presented in a manner that leads to an early preference advantage for that alternative.

Most of the biases described previously leverage the lack of involvement and/or motivation to carefully process information (*see* CONSUMER INVOLVEMENT). Fortunately, consumers do not always process information using heuristics and low effort. Important decisions are likely to be guided by judgments and evaluations formed on the basis of a systematic analysis. Dual process models, such as the elaboration likelihood model (ELM) or the heuristic systematic model, suggest that there are two qualitatively different routes to persuasion: a high involvement route in which consumers think a lot (*i.e.*, the central route of the elaboration likelihood model and the systematic route of the heuristic/systematic model) and a low involvement route in which consumers think very little (*i.e.*, the peripheral route of the elaboration likelihood model and the heuristic route of the heuristic/systematic model; Chaiken and Trope, 1999).

The ELM suggests that when involvement is high, and when the ability to think about an ad is high, consumers are likely to follow the central route to persuasion by focusing on information that is most central to or important for forming an accurate attitude. Consumers are less prone to process the information passively. Instead, consumers are likely to elaborate on a persuasive message by generating their own support arguments or counterarguments. Strong arguments and strong reasons for forming a particular attitude are particularly persuasive when consumers follow the central route to persuasion. Attitudinal judgments formed on the basis of highly compelling arguments are likely to be enduring, resistant to change, and more likely to influence behavior.

When involvement is low or when the ability to think about an ad is low because of distraction,

a lack of relevant knowledge, time pressure, and so on, consumers are likely to follow the peripheral route to persuasion without evaluating the quality of the arguments supporting or refuting a given position. Following the peripheral route to persuasion by focusing on peripheral or superficial information makes it easy to form an opinion without much thought. Many different types of superficial cues may be used. Attractive, likable, and expert sources seem trustworthy, so if these sources say that an advertised brand is a good product, consumers often believe these sources rather than spending a lot of time thinking about the attributes and benefits of the product (*see* SOCIAL INFLUENCE). Furthermore, positive moods and feelings often transfer to the advertised brand when consumers follow the peripheral route to persuasion. Consumers tend to form weak attitudes that are not accessible from memory, not long lasting, not resistant to change, and that have a weak influence on other judgments and behavior.

The ELM indicates that facts and reason are important when consumers follow the central route to persuasion, but not when consumers follow the peripheral route to persuasion. The model also indicates that celebrities, authority figures, humor, and pleasant background music and scenery are important when consumers follow the peripheral route to persuasion, but not when consumers follow the central route to persuasion. Hence, consumers use different types of information depending on which route to persuasion they are following. Furthermore, the central route to persuasion leads consumers to form strong attitudes that are accessible from memory, persistent, resistant to change, and that have a strong influence on other judgments and behavior (Haugtvedt and Kasmer, 2008; *see* CONSUMER INTENTIONS).

MEMORY

Availability refers to information that is stored in memory, and accessibility refers to the “activation potential” of the available information (Wyer, 2008). Accessibility depends on the strength of the association between stored knowledge and situational cues, the recency with which information has been acquired or last activated, the frequency of prior activation, and

4 consumer information processing

the intensity with which information has been processed (*see* KNOWLEDGE ACCESSIBILITY). Rather than using all relevant information stored in memory, consumers frequently use the subset that has been activated or primed by stimulus cues. The priming paradigm consists of two phases: first, consumers are exposed to a stimulus that increases the accessibility of the primed construct; second, consumers perform a seemingly unrelated task and their judgments or behaviors are assessed. When the applicability of a priming stimulus relative to a target is high, the stimulus influences subsequent judgments and behaviors concerning the target.

A wide variety of marketing communications have been shown to serve as priming stimuli (e.g., ads, Internet messages, salesperson interactions, retail environments, consumer magazines), and these priming stimuli have been shown to influence a wide variety of judgments (e.g., expensiveness, evaluative, and likelihood judgments) and mind-sets (e.g., comparing brands in one product category can increase purchase intentions in a different product category). Consumers often overestimate the likelihood of occupations (e.g., doctors, lawyers), objects (e.g., luxury cars, swimming pools), and behaviors (e.g., having wine with dinner, incidence of crime) shown frequently on television. This is particularly the case for heavy viewers, despite the fact that most consumers do not believe that television reflects reality accurately. With respect to evaluation, priming can result in either assimilation (a shift in judgment of a target toward the priming stimulus) or contrast (a shift in judgment of a target away from the priming stimulus), depending on the degree of overlap between the priming stimulus and the target. Assimilation occurs when overlap is high, and contrast occurs when overlap is low.

There is usually a considerable gap between the point of time at which information about products or services is encountered and the point of time at which this information is used in order to make a purchase decision. That is why it is of crucial importance to understand the role of memory in decision making (*see* CONSUMER MEMORY PROCESSES). Memory enables past experiences and learning that occurred long ago to influence current behavior. Memory is often compared to a computer (Kardes *et al.*, 2011).

A computer has a hard drive that can store a large amount of inactive files. A computer also allows users to retrieve a file from the hard drive and make it active so that the file can be processed (e.g., edited or used). Similarly, people have a long-term memory system that stores a large amount of inactive data or knowledge. To use this knowledge, people must retrieve it from long-term memory and bring it in into short-term, active memory so that the information can be processed. The transfer from the short-term memory to the long-term memory happens through rehearsing the information. The entire thinking and reasoning occurs in short-term memory, and only a small amount of information can be held in short-term memory; consistent with Miller's magic number seven, consumers cannot hold more than seven brands in their short-term memory (Kardes *et al.*, 2011). If this information is not used, it can be lost in as little as 18 seconds. By contrast, long-term memory appears to store an unlimited amount of information permanently.

Memory can have an impact on diverse dimensions of brand choice: the brands included in the consideration set, what information will be used to evaluate the considered brands, and how the information will be used. Three general types of brand choice can be distinguished (Lynch and Srull, 1982). First, stimulus-based choice involves the selection of one brand from a set of brands that are actually present at the time of choice. For example, consumers in a grocery store might occasionally consider the brands that are on the shelves directly in front of them, not considering any brand retrieved from memory. Purely memory-based choice involves electing a brand from a set of brands stored in memory. Good examples of this type of choice include picking a restaurant before one leaves home. In between these two alternatives, mixed brand choice involves both alternatives that are physically present and alternatives that are retrieved from memory. This type of choice happens when consumers compare products from different stores that carry different brands (Kardes, 1994).

The usual comparison of memory to a computer does not imply that memory is infallible. For example, forgetting occurs. Forgetting is not because of information loss

or decay. Instead, forgetting occurs because we cannot find the information we are trying to find during memory search. In addition, information held in long-term memory can also be distorted or changed over time (Kardes *et al.*, 2011).

Selective processing also influences how information is stored in memory. Advertising can change the manner in which products are experienced. Subjective product experiences are ambiguous and might be interpreted in multiple ways. When an ad states that a particular brand of soda tastes sweet and refreshing, consumers frequently test this hypothesis by searching for hypothesis-consistent information in their memory (i.e., confirmation that the soda is indeed sweet and refreshing), and this leads to premature confirmation of the advertisement claim. When the ad precedes the experience, it sets expectations that will guide the interpretation of the product experience. Learning from experience becomes difficult because prior beliefs and current experiences are perceived as more consistent than they actually are. Conversely, current belief might bias memory. For example, a consumer might be led to believe that product A is better than product B. But, if at a later time, the consumer is led to believe product B is better than product A, the consumer is likely to distort his memory and report that he thought that product B was superior all along. Selective search can occur for stimulus information or for information stored in memory, depending on the timing of the ad and the consumption experience.

Most retail settings offer only a limited set of brands, and the brands that are offered often determine which brands are included in consumers' consideration sets, or the group of brands that are considered for purchase by consumers. Consumers are more likely to focus on immediately available brands and neglect unmentioned brands in singular judgment task (Kardes *et al.*, 2011).

The neglect of unmentioned brands increases as the number of brands presented increases because of part-list cuing-induced inhibition (Kardes *et al.*, 2011). This type of inhibition is different from intentionally blocking or suppressing examples available from memory. It occurs when just some brands are presented and consumers are trying to recall as many brands as

possible. The brands presented inhibit the recall of other brands. Similarly, advertising reduces the ability of consumers to recall attribute information pertaining to competing brands. Inhibition of nonfocal brands also occurs when focal brands are physically present (as in grocery stores) rather than mentioned only by name. When no brands are mentioned by name, consumers are forced to generate their own consideration sets via memory search, and this leads to a strong advantage to brands enjoying strong brand-category associations in memory. Consumers often demonstrate selective memory for previously chosen products.

CHOICE

All the previous stages of information processing (attention, comprehension, and memory) are important in order to make a purchase decision (i.e., a choice). Selective processing often leads consumers to focus on one brand. Leveraging the effect of part-list cuing, marketers often try to influence which brands and how many brands consumers will include in their consideration sets. Marketers also leverage other effects, such as the attraction effect and the compromise effect (Kardes *et al.*, 2011; *see* CONSUMER DECISION MAKING).

The attraction effect is based on the principal that a given brand seems more attractive when it is compared to inferior brands and less attractive when compared to superior brands. Hence, marketers want consumers to compare their brands to inferior brands. This can be done in a selling situation or using comparative advertising and promotion where the target brand is shown to be superior to other brands on some dimension. Alternatively, the attraction effect can come into play when a firm has multiple brands in its product line. For example, when a company markets a relatively expensive product, it might appear as too expensive when presented with no point of comparison. As a result, few consumers might choose to purchase the product. If the company introduces a more expensive product that competes directly with the first product, the original product might appear as more reasonably priced and much more attractive. This gives the impression to consumers that they save

6 consumer information processing

money while the characteristics of the original product remain unchanged.

Another way to improve the evaluation of a target brand is to make this brand seem like an average, or a good compromise, relative to other brands in the consideration set. A compromise brand seems average on all important attributes or features; other brands often have some really good features and some really bad features, but a compromise brand does not seem to have any very bad features and is at least acceptable on all features. Hence, the compromise brand seems like a safe choice and the compromise effect, or the increased likelihood of buying a compromise brand, is particularly likely to occur when consumers are concerned about avoiding a bad decision. Brands that are intermediate or “average” in terms of price, quality, and number of features are frequently chosen from the consideration set, and they are chosen even more frequently when we have to justify our choice to others. Because it is often easier to justify the purchase of intermediate rather than extreme brands, such a choice might also reduce post-decision regret. Of course, almost every brand can appear to be a compromise brand depending on what brands serve as points of comparison. Advertising and promotion campaigns that encourage consumers to compare a seemingly average brand to more extreme brands increase the influence of the compromise effect.

Selective processing leads consumers to use a number of heuristics to make choices (Kardes *et al.*, 2011). An important aspect of making a purchase decision is based on the ability to predict the future performance of a product. Although the ability to make predictions is very important, research evidence suggests that people are not very good at making them. This is because people often unknowingly use heuristics to generate predictions. Such heuristics include the representativeness heuristic, the availability heuristic, the simulation heuristic, and anchoring-and-adjustment heuristic.

People using the representativeness heuristic make predictions based on the perceived similarity between a specific target and a general category. Consumers can make mistakes when they focus on superficial similarities between

an object and a category (e.g., focusing on irrelevant similarities like package color and graphics). People using the availability heuristic make predictions based on the ease with which instances are retrieved from memory. For example, if an event is highly memorable and easy to remember (a service failure), it might overpower the availability of other less memorable events (e.g., several flawless interactions with the same service provider). If it is easy to remember, it seems more likely to occur. This will affect the prediction of consumers if they have to interact again with the same service provider. People using the simulation heuristic make predictions based on the ease with which an event or a sequence of events can be imagined or visualized. Such a heuristic has important implications for health-care marketing. Consumers with high blood pressure often forget to take their medicine because the symptoms usually are not that bad and this makes it difficult to imagine that their condition is serious. People using the anchoring-and-adjustment heuristic make predictions based on a first impression or an initial judgment (or anchor) and then shift (or adjust, or fine-tune) this judgment upward or downward depending on the implications of the imagined possibilities. Unfortunately, we usually fail to adjust enough and the effect of the anchor can remain more impactful than it ought to be. As a consequence the final judgment is often close to the initial impression.

In addition to heuristic that influence predictions related to decision making, there are also heuristic strategies related specifically to consumer choice (Kardes *et al.*, 2011). These heuristics include the lexicographic heuristic, the elimination-by-aspects heuristic, the additive-difference heuristic, the conjunctive and disjunctive heuristics, and the frequency of good and bad features heuristic. Consumers using the lexicographic heuristic (or single-attribute heuristic) compare all brands on one attribute, and choosing the brand that performs the best on that single attribute, generally ignoring the other attributes. If there is a tie, consumers examine the next most important attribute to break the tie.

Another choice heuristic is the elimination-by-aspects heuristic. Consumers simply reject brands that do not have a key feature that they want. Next, consumers would focus on a different attribute and reject all brands that do not meet their requirements on this attribute, and so on. Consumers using the additive-difference heuristic compare two brands at a time (rather than all brands) on one attribute at a time and subtract the difference. Subtraction is performed on all relevant attributes and each attribute is weighted for importance—each difference is multiplied by the importance of the attribute. Each weighted score is then summed to arrive at an overall score for each brand.

Choice heuristics do not always involve making comparisons across brands. Sometimes we focus on one brand at a time and no comparisons are performed. Examining one brand at a time is easy, and if the first brand seems satisfactory you might buy it without examining any other brands. Consumers using the conjunctive heuristic set a minimum value for all relevant attributes and select the first brand that meets this value for all relevant attributes. Consumers using the disjunctive heuristic set an acceptable value, rather than a minimum value, for all relevant attributes and select the first brand that meets this value on one attribute, rather than all of the attributes. The frequency of good and bad features heuristic is a strategy in which consumers form a simple attitude toward each brand alternative by counting the number of good product features, counting the number of bad product features, and choosing the brand with the largest number of good product features.

CONCLUSION

Consumer judgment and decision making is influenced by a large and complex set of variables that capture the attention and interest of consumers; influence how consumers acquire, retain, and revise product knowledge; and influence how product knowledge is used to ultimately make judgments and decisions. Selective processing is likely to have an impact on every stage of consumer information processing (e.g., selective attention, selective

encoding, selective retrieval). Dual process models emphasize that effortful information processing, which reduces selective processing, heuristic processing, and the biases resulting from selective or heuristic processing, depends on the motivation and ability to process information carefully. Consumer information processing has important implications for understanding how consumers make judgments and decisions, and how policymakers can help consumers make better judgments and decisions.

the role of schemas in consumer behavior research

Karen E. Flaherty and John C. Mowen

INTRODUCTION

Social and cognitive psychology researchers assume that because our information processing capabilities are limited, we develop abstract knowledge structures. One form of knowledge structure that has been extensively studied in both the psychological and consumer behavior literatures is the schema. A schema is defined as a "... *cognitive structure that represents knowledge about a concept or type of stimulus, including its attributes and the relations among those attributes*" (Fiske and Taylor, 1991, p. 98). Schemas are an individual's preconceived notions or ideas about the world that are stored in memory.

The schema concept stems from a combination of Heider's (1958) balance theory and Asch's (1946) person perception research, wherein people are believed to form general holistic perceptions from discrete social encounters (Fiske and Taylor, 1991). The basic premise of schema-driven research is that in order to simplify reality, we develop categories (*see* CONSUMER CATEGORIZATION) in which to store information at a broader level rather than attempting to incorporate specific experiences and new information in a piecemeal fashion. In essence, schemas serve to ease our information management processes and social experiences. Categories are formed to help us discriminate among individuals, interpret information, and evaluate others. When evoked, schemata are believed to influence social perceptions and evaluations as well as behavior. While schema research focuses largely on understanding and describing the result of the evoked schema on such outcomes, categorization research focuses on how instances are classified and categories (or schemas) are formed. In this article, we limit our discussion to schema research.

TYPES OF SCHEMAS

Various types of schemas have been studied across a number of disciplines, including social psychology, consumer behavior, marketing, and

organizational behavior. For instance, categories and schemas have been proposed to capture individual's perceptions of themselves, other people, roles and occupations, and the situations they face. A person (or other) schema represents preconceptions of a variety of personality traits, social goals, and so on. For example, an individual may have a preconceived idea of what it means to be outgoing or competitive (e.g., Cantor and Mischel, 1979). A self-schema represents perceptions of the self, or the core of the self-concept (Markus and Wurf, 1987). Self-schemas tend to be more complicated than other schemas, and as a result people remember better self-relevant information (Kihlstrom *et al.*, 1988). Role schemas capture our understanding of the characteristics and behaviors that we expect of people in certain roles and positions, including both achieved (e.g., professor, graduate student, janitor) and ascribed (e.g., race, age, gender). Event schemas represent our expectations regarding how events ought to be sequenced – much like scripts (e.g., what should happen when you go to a wedding, a funeral, or a dinner party). These types of schemas and others that have been proposed in the literature all serve to guide our information processing and social encounters with greater efficiency and ease.

THE EFFECTS OF SCHEMAS

In general, people balance a schema stored in memory against actual evidence received in the environment. Thus, external information is weighed against internal preconceived notions. In addition, schemas affect how individuals encode, remember, and evaluate information that is encountered after an initial schema is evoked. When a new piece of information or a new encounter takes place, it evokes an existing schema. In turn, the schema impacts the person's attention to the information, how the person interprets the information, and the basic judgments that are formed from the information.

Attention. Schemas affect what people notice. When an individual has a strong preconceived notion of a given subject or object (i.e., the schema is well developed), then the person is likely to pay close attention to schema-consistent information and to ignore schema-inconsistent

2 the role of schemas in consumer behavior research

information (Fiske and Neuberg, 1990). Schemas also minimize perceptions of differences across those within the schema (e.g., all scientists are alike) and increase perceptions of differences between schemas (e.g., scientists and janitors are very different).

Memory. Schemas also affect what people remember (see CONSUMER MEMORY PROCESSES). In addition to its effects on attention, research suggests that when an individual has a well-developed schema, he or she is also more likely to remember schema-consistent information (Fiske and Neuberg, 1990). However, if an individual does not have a well-developed schema, then both consistent and inconsistent information will be processed and remembered. The individual is still attempting to form a solid perception of the category and as a result will attempt to integrate the new information.

Evaluations. Immediate evaluative responses are a result of the affect triggered by categorization to a specific schema (Anderson and Cole, 1990). When actual data or evidence is encountered, an existing schema is evoked. When the evidence is consistent with the activated schema and the schema is positive, then a positive evaluation is triggered. Hence, there is a schema congruity effect (Mandler, 1982). In effect, our evaluations are driven by the degree of schema (in)congruity that we perceive when encountering a new piece of evidence. The new evidence received in conjunction with the existing schema forms the evaluation. It should be added, however, that an increasing body of literature indicates that a moderate level of incongruity between a product and a more general product category can stimulate information processing. In turn, this can lead to more favorable evaluations in relationship to products that are congruent or extremely incongruent with the schema (Meyers-Levy and Tybout, 1989).

The next section of the article briefly reviews four key theoretical areas in schema research. We then identify several areas for future research.

FOUR KEY THEORETICAL AREAS

Researchers have employed schema theory as the foundation for investigating a variety of applied areas of consumer behavior, including

advertising, personal selling, public policy, branding, and product management. Rather than reviewing research in these applied areas, however, we have chosen to investigate contributions of consumer and psychological researchers to four key theoretical areas: (i) the effects of the level of schema congruity, (ii) the relationship of semantic memory networks to schema, (iii) the effects of moderating variables, and (iv) the impact of self-schemas on consumers.

The effects of level of schema congruity. A substantial number of studies have investigated the effects on information processing and evaluative judgments of the level of congruity between the schemas for a consumer product and its associated product category. In this case, congruity or incongruity may be defined as the extent to which the holistic configuration of attributes associated with an object and the configuration of the existing schema for the product category correspond (Mandler, 1982). In general, this research follows the logic developed by Fiske and colleagues (e.g., Fiske and Neuberg, 1990) in the social psychology literature, the work of Sujan (1985) in the consumer behavior literature, or Mandler's (1982) schema congruity hypothesis. This research suggests that when the product (or other object) matches the evoked schema, then affect transfer from the evoked category to the object occurs. In contrast, when a mismatch is perceived, more elaborate processing will be triggered. In other words, in the case of congruence (or a match), holistic processing based on the schema will take place; however, when incongruent (or a mismatch), judgments will be derived in a piecemeal fashion.

As a general statement, the literature suggests that people react positively when objects conform to expectations, and as a result are congruent with existing schema (e.g., Fiske, 1982). Mandler (1982) added to the literature, however, by proposing that objects that match the existing schema are unlikely to elicit deep cognitive processing. Therefore, the positive response generated by congruence will be weak. Conversely, when the object is incongruent with the existing schema, deeper cognitive processing is likely to be triggered. In some instances these

incongruities can be easily resolved through a process in which the individual recognizes that the object is just another example of the category. Thus, the object is recognized as a special case of an existing category (i.e., subtyping). Alternatively, the object may be recognized as residing in another category (i.e., alternative classification). Mandler (1982), and later Meyers-Levy and Tybout (1989) in the consumer behavior literature, suggest that the process of rectifying perceptions of incongruity between the object and the evoked schema will influence evaluative responses, and the process of successfully resolving the inconsistency can lead to greater positive affect. In contrast, however, extreme incongruities that cannot be easily rectified are likely to result in a negative affect. Meyers-Levy and Tybout (1989) argue that the positive effect of moderate incongruity is lacking in studies taking the Fiske (1982) approach because the effect of the process or responding to incongruity is subtle and likely to be overwhelmed when general affect toward the product or existing schema is very strong.

Again, many consumer studies take this approach. For example, Braun-LaTour, Puccinelli and Mast (2007) apply Mandler's hypothesis to investigate the effects of mood and information overload on consumer processing of ads. Their results indicate that reaction times are faster when categorizing congruent information than when categorizing incongruent information. Also, consumers in a positive mood were found to categorize faster.

The role of memory and semantic networks in schema research. Another approach adopted in the study of schemas involves the study of memory (see CONSUMER MEMORY PROCESSES) and semantic networks. For example, the spreading-activation theory or semantic processing proposed by Collins and Loftus (1975) is employed in social psychology and some consumer behavior research to better understand the role of memory in schemas. The spreading-activation model links concepts (or nodes) via a network. When one concept is activated, it spreads to other related concepts. Concept nodes are linked together and usually flow in both directions. Further, the links

between the concept nodes will vary in "criteriality" or strength. Thus, it might be highly criterial that one concept is linked to another concept in memory (e.g., an apple node is linked to a fruit node so that an apple is recognized as a piece of fruit), but less criterial for it to be linked to another (e.g., the apple node is linked to a yellow color node). The theory suggests that when a concept node is activated, activation spreads to other nodes via the connected paths of the network. The level of activation decreases as it spreads further across the network. Thus, concepts further removed from the initial concept node that was activated will be weakly triggered while those closer are more strongly triggered. Furthermore, activation can only start at one node at a time, and activation goes away gradually or decreases over time.

Braun-LaTour and LaTour (2004) apply concepts from spreading-activation theory in an advertising study. They argue that when a consumer is exposed to an advertisement, brand-related concepts are activated. Concepts related to the spokesperson and/or the message may also be activated. Associations between the links become more automatic and stronger with repetition. Thus, a continuous ad campaign will result in better recall and recognition among consumers than a new campaign. Although not surprising, the results are consistent with schema congruity theory.

Moderation effects. Consumer researchers have identified a number of variables that moderate consumers' schema processing strategies. For example, Yoon (1997) finds that older adults exhibit greater use of schema-based processing strategies than younger adults. However, this effect is found only during nonoptimal times of the day, which for older adults is during the evening hours. In contrast, younger adults engage in detailed processing strategies regardless of the time of day.

An important finding in the schema literature is the "moderate incongruity effect" in which people prefer an option that is moderately inconsistent with a product category schema to one that is congruent with the product category schema. In two studies, the effect is found to be moderated by other variables. First, Peracchio and Tybout (1996) find that the effect occurs

to a greater extent when consumers have little prior knowledge of the product category. Thus, when consumers are knowledgeable of a product category, the “moderate incongruity effect” disappears. Campbell and Goodstein (2001) extend the research by investigating the role of perceived risk on the “moderate incongruity effect.” Consistent with previous research, the authors find that moderate incongruity results in more detailed processing and evaluations that are more positive than in congruity conditions. However, perceived risk is found to moderate the effect. That is, the moderate incongruity effect is found only in low-risk product selection conditions. If perceived risk is high, then congruity (rather than moderate incongruity) leads to a more favorable evaluation.

The “moderate incongruity effect” is also investigated from the perspective of the elaboration-likelihood paradigm. In a study of ad-brand incongruency, Dahlén *et al.* (2005) find that when an ad is incongruent with a brand schema two things occur. First, the attitude toward the ad decreases. Second, brand attitude evaluations increase along with the amount of brand-related information processing. These effects are moderated, however, by the respondents’ need for cognition, such that the increased brand attitude and information processing occur only among the high need for cognition respondents. Consistent with these findings is research by Lee and Thorson (2008), who find that a moderate incongruence between celebrity and product schemas increases the persuasiveness of an endorsement, but the effect is most pronounced among participants with higher levels of product involvement. Both of these studies can be interpreted from within the elaboration-likelihood theory paradigm. That is, those higher in the need for cognition and those with higher levels of product involvement engage in greater levels of information processing, which allows the respondents to cognitively handle the information in the moderate incongruency conditions.

In an interesting study, Aggarwal and McGill (2007) investigate the role of schemas in evaluating anthropomorphized products. The results of their first two studies reveal that the greater the extent that a product matches the schema

for what a human looks like, the more positive the evaluation of the product when the text of the ad anthropomorphizes the product. For example, in one of the experiments an automobile is depicted as talking to the consumer when the ad begins “Hi, I am a Lexus.” A third study, however, shows that the findings depend upon whether the affective tag associated with the human schema is positive. Thus, if the human schema that is activated is negative, the evaluation of the brand becomes more negative. In the study, beverage bottles are shown in pairs. In the copy of the ad, the bottles are described as either good twins, who will make their parents proud, or as evil twins who will conquer your city. The results reveal that the affective tag of “good twins” versus “evil twins” moderates the results. Thus, the evaluation of the brand is enhanced in the “good twin” condition in comparison to the “evil twin” condition. This study is important because it shows that schema congruity can increase or decrease evaluations depending upon the affective tag associated with the schema that is evoked.

The role of self-schemas in consumer behavior.

Aaker’s (1999) research on the effect of self-schemas on consumer attitudes toward a brand provides the foundation for additional work on self-schemas in a branding context. Aaker proposes that the self (*see POSSESSIONS AND SELF*) is malleable and that one’s self-schema is influenced by personality and situational factors. Various self-conceptions (i.e., self-schema) may be activated or deactivated depending on how salient they are, which can be influenced by the existing social situation or by the traits that are evoked by a particular experience or memory. In her research she focuses on those traits that are deemed to be schematic because they are at that moment descriptive or important to the individual. Consistent with social psychology research, Aaker argues that people maintain a self-schema because they desire consistency and positivity. When presented with information that is inconsistent with the self-schema, then individuals are less likely to accurately recall the information. Further, negative affect is more likely to result if self-relevant information is inconsistent with the self-schema.

Aaker (1999) proposes that a brand (and the set of personality traits that the brand embodies) often serves a “self-expressive” purpose for consumers. As consumers, we select and utilize brands that allow us to make a certain impression or that best represent us at a given point in time. As a result, consumers who are schematic on a particular personality trait should demonstrate a preference for brands that are also highly descriptive on that trait. Aaker refers to this as “self-congruity.” While consumers’ schematic traits typically guide their behavior, she also acknowledges that sometimes consumers’ behaviors express who they wish to be (desired self) or strive to be (ideal self) rather than the actual self. Thus, each individual holds a variety of self-conceptions. She also suggests that depending on the current social situation, certain situational cues can become salient and influence the conceptualization of the self so that one trait self-schema is more acceptable than others. On the basis of these situational cues, people will tailor their behavior to match the trait that is primed by the situation (i.e., “situation congruity” takes place).

Batra and Homer (2004) adopt Aaker’s schematicity framework in their research on brand image beliefs. They find that personality associations of celebrity endorsers serve to reinforce consumer beliefs about the brand. That is, if the spokesperson is perceived to be fun or sophisticated, then the brand is likely to be perceived to be more fun or more sophisticated. For brand image beliefs to be evoked, the brand’s schema needs to fit the consumer’s schema. Consistent with these findings, Worth, Smith and Mackie (1992) find that brands are evaluated more favorably if the description of the brand matches the consumer’s self-schema. More specifically, these authors found that the gender schematicity of the respondents is assessed in terms of its degree of masculinity versus femininity. Respondents prefer products whose description matches their self-perceived schema for masculinity or femininity. Similar findings are found for self-schema based upon the separateness–connectedness of the subjects (Wang and Mowen, 1997). Thus, respondents who rate themselves as more connected to others preferred products described in terms of their ability to bring people together. In contrast,

respondents who rate themselves as more separated prefer products described in terms of their ability to help maintain the person’s individuality.

DIRECTIONS FOR FUTURE RESEARCH

One direction for future research involves the investigation of the nature of self-schemas. In the development of the 3M Model of Motivation and Personality, Mowen (2000) and his colleagues (e.g., Mowen and Sujan, 2005) propose a control theory model in which a system of personality traits provides a schema for interpreting stimuli and outcomes as well as for influencing attitudes and behavior. Thus, traits do not operate in isolation of each other. Rather, in conjunction with situational forces, multiple traits combine to form a schema that influences attitudes and behaviors. Importantly, past research has tended to investigate how single personality traits (e.g., need for cognition or extroversion) influence evaluations if they are congruent or incongruent with the description of a product. For example, as noted earlier, masculinity–femininity and separateness–connectedness can be conceptualized as traits and have been shown to positively impact brand evaluations if appropriately matched to a product’s description. To the present authors’ knowledge, however, researchers have not investigated multiple traits acting together in experimental studies.

How can an advertisement, brand, or endorser simultaneously activate a schema associated with multiple traits? Consider the development of a television advertisement. These ads will have multiple elements, including a message, music, a situational context, and perhaps an endorser. Each ad component can be used to activate a different personality trait. For example, the message could be composed of high-quality arguments, which would appeal to an individual high in the need for cognition. Similarly, the music could be based upon a song that emphasizes togetherness (e.g., “Love Will Keep Us Together”), which would activate a connectedness trait. The situation could be composed of a party atmosphere in which an endorser who is shown to be highly gregarious, which would activate an extroversion trait. These ideas suggest that a critical aspect of developing TV ads is

the art of combining music, copy, situation, and endorser so as to effectively activate schema that are maximally congruent the product's schema as well as the self-schema of the target audience. These ideas also illustrate the crudeness of present schema research, which looks at only one trait at a time.

The idea that multiple traits act to form a self-schema suggests the possibility of bringing science into the art of creating advertisements. We believe that the complex interaction among a multitrait person schema, a product schema, and a situational context is why the development of advertisements can be described as an art. One possibility for incorporating a greater level of science into the art, however, is by identifying the trait antecedents of the specific behavior that ad developers hope to influence. In the hierarchical structured 3M Model, these highly specific behavioral dispositions are called *surface traits*, which emerge in part from combination of deeper level traits, including situational, compound, and elemental traits.

Here is an example. Suppose that the advertiser is marketing a product that is positioned as the leader in its field. The goal is to attach a leadership schema to the product. This schema would be based upon traits that are associated with individuals having a strong leadership propensity. The goal would be to create an advertisement that portrays a product schema that is congruent with a leadership self-schema. Research by Flaherty *et al.* (2009) identifies the system of traits of individuals with high levels of leadership propensity. This self-schema includes the deeper level traits of competitiveness, self-efficacy, and the need for material resources. With this information it would be straightforward to create an advertisement that employs an endorser who is self-confident (i.e., indicating self-efficacy), that takes place in a luxurious setting (suggesting materialism), and that includes music suggesting competition (e.g., the song "Eye of the Tiger"). Schema theory suggests that such a high level of congruity between the product's schema and self-schema of the target market should enhance the effectiveness of the advertisement. Future research, however, is required to test these ideas.

A second arena for future research involves integrating the research on schema congruity

with the literature on fit and the match-up hypothesis. For example, Till and Busler (2000) propose that a match-up occurs when there is a fit between the characteristics of the product spokesperson and the product that is endorsed. That is, when fit, match-up, or similarity occurs between two entities, there is a greater likelihood of the transfer of knowledge and affect from one stimulus to another. This idea is consistent with both spreading-activation theory and balance theory, which places the literature squarely within the domain of schema congruity.

The concepts of fit and match-up have been applied to numerous cases in which congruence is sought in the characteristics between two entities. Across the studies, however, the authors are inconsistent in whether they cite the literature on schema congruity. The following are examples of the topics of studies investigating stimulus congruity from the perspective of fit and/or match-up.

- Fit of endorser with product
- Fit of country-of-origin with product
- Fit of style of music with brand image of retail store
- Fit of music with advertising message
- Fit of product extension with brand
- Fit of brand image with social cause in cause-related marketing
- Fit of advertisement with TV program
- Fit of product with TV program
- Fit of product with an ambient scent/smell
- Fit of attractiveness of service provider with nature of the service.

Each of the pairs of entities can be investigated from the perspective of schema theory. As such, the two literatures should be integrated. Interestingly, while the authors of the studies focusing on match-up/fit will sometimes cite schema theory, the authors investigating phenomena from a schema congruity perspective far less frequently cite the literature on match-up/fit.

The present authors believe that a key goal for future research is the development of a general model that could be possibly called the "schema congruency theory." The model will require the development of an enhanced version of schema theory that is able to explain

the effects of moderating variables as well as handle the multifaceted nature of schema. The new theory of schema congruence would then be able to explain and predict consumer reactions to the level of congruency, which includes issues of match-up/fit among stimuli, whether product-based, self-based, other person-based, and/or situation-based.

consumer intentions

Richard P. Bagozzi

An *intention* has been defined as a *person's commitment, plan, or decision to carry out an action or achieve a goal* (Eagly and Chaiken, 1993), and in fact has been used synonymously at times with choice, decision, and plan. All these usages more generally fall under the label *volition*. Psychologist Ajzen (1991, p. 181) conceives of intentions rather broadly as “indicators of how hard people are willing to try, of how much of an effort they are planning to exert.” This definition seems too broad in that it encompasses (i) motivation, which is better construed as an antecedent of intention and (ii) planning, which constitutes a mental activity or process that often occurs after one forms an intention to pursue a goal or perform an action.

The need for a narrower definition of intention can be seen in Lewin's (1951, pp. 95–96) specification of the role of volition in action: “[A] complete intentional action is conceived as follows: Its first phase is a motivational process, whether a brief or a protected vigorous struggle of motives; the second phase is an [mental] act of choice, decision, or intention, terminating this struggle; the third phase is the consummatory intentional action itself.” This clearly differentiates intention from motivation and action and situates it between these concepts: motivation→intention→action.

The most common type of intention is the personal or I-intention to pursue a goal or perform an action by oneself. Notice that one can have an intention to pursue a goal, accomplish an end, or produce an outcome (“I intend to lose body weight”) or an intention to execute an act (“I intend to buy a new LED television”). Both goal intentions and action intentions can be expressed noncontingently, as phased above, or contingently (e.g., “I intend to buy a new LED television, as soon as the price drops below \$3000”).

Gollwitzer proposed an important kind of intention, which he termed, *implementation intentions* (e.g., Gollwitzer and Brandstätter, 1997). These involve planning when, where, and how to act. Typically, a gap in time, often significant, exists between intention formation

and behavioral execution. Implementation intentions serve cognitively to provide mental representations of opportunities to act and volitionally “create strong mental links between intended situations and behavior” and “in the presence of the critical situation, the intended behavior will be elicited automatically” (Gollwitzer and Brandstätter, 1997, p. 196). Thus one's intention to buy milk at the end of the day, made in the morning before work begins, may be recalled by the sight of a favorite store that one passes while returning home from work and enacted straight away. Because intentions frequently form first and lead to planning, many researchers might prefer to term “implementation intentions,” *planning*, to allow for separate mental states and processes in this regard.

Intentions might lead directly to action straight away or after a gap in time. But they also have been shown to differ in degree of well-formedness and to be moderated in their effects by level of effort required in action execution and by correspondence or independence between goal commitment and planning. Further, various mediators may occur between intentions and behavior, such as the need to deal with temptations, impediments, weakness-of-will, and monitoring progress in goal pursuit. For a review of moderators and mediators of the intention-action linkage, see Bagozzi (2006a, p. 19ff).

A common role for intentions in so-called goal-directed action is to bridge desires and their downstream effects. The consumer core captures this role of intentions and can be expressed as follows: goal desire→goal intention→action desire→action intention→action (see Bagozzi, 2006b). An important way that self-regulation occurs is in the management of the desire-to-intention links sketched above (see Bagozzi, 2006a, 2006b). Here desires are modulated through the imposition of personal standards of conduct, ethics, or moral imperatives. (see also SELF-REGULATION; CONSUMER DESIRE).

Recently the meaning of intentions has been expanded to include shared or collective intentions (Bagozzi, 2000, 2005). Thus, for example, persons in an intimate relationship might speak of “our intention to see Tchaikovsky's Swan

Lake”; a football player may mention “the team’s plan to implement a new defensive scheme”; corporation spokespersons might announce “the firm’s hostile intention to take over another firm”; and the President of a country might remark that “our people intend to eliminate poverty by 2020.” These examples – referring, respectively, to a two-person dyad, a small group, an organization, and a collectivity – illustrate that people often use social notions of intentions in ordinary speech, whether referring to informal or formal groups.

There are two types of collective intentions. One is a personal intention to do something with a group of people or contribute to, or do one’s part of a group activity (e.g., “I intend to prepare the holiday dinner with my sisters”). Notice that a person can have an intention to act as an actor, yet the action can be self-construed as an individual act performed alone (an I-intention to do an individual act by oneself) or as a member of a group (an I-intention to do one’s part of a group act). The latter is one type of collective action.

A qualitatively different form of a collective intention is what might be called a *we-intention*. A we-intention is a collective intention rooted in a person’s self-conception as a member of a particular group (e.g., an organization or institution) or social category (e.g., one’s gender or one’s ethnicity), and action is conceived as either the group acting or the person acting as an agent of, or with, the group. A we-intention can be expressed in two forms: a shared we-intention articulated in the form of “I intend that our group/we act” (e.g., “I intend that our family visit Sea World, San Diego, next vacation”) or a communal we-intention explicated in the form, “We (i.e., “I and the group to which I belong”)

intend to act” (e.g., “We intend to sponsor an exchange student in our home next year”). Collective intentions open up new avenues for exploring consumer behavior and are grounded in plural subject theory (Bagozzi, 2000, 2005).

Traditionally, such psychological determinants of behavior as attitudes, motives, emotions, values, felt social pressure, self-efficacy, and perceived behavioral control have been conceived to work through intentions to influence behavior. More recently desires have been considered to be proximal causes of intentions, channeling the effects of multiple psychological determinants (see consumer desires in this volume).

consumer behavior across literacy and resource barriers

Madhu Viswanathan

With few exceptions (Hill, 1991; Alwitt, 1995; Arnould and Mohr, 2005), much of what is known about consumer behavior has come from studying relatively resource-rich, literate consumers, usually in advanced economies. This article focuses on low-literate, low-income consumers in the United States and subsistence consumers in India, that is, those living in circumstances of widespread poverty. Each of these groups is described and compared and contrasted with what is known about consumer behavior in more conventional settings. Thus, the focus is on consumer behavior across literacy and resource barriers. Implications for marketing in general are also briefly discussed.

LOW-LITERATE LOW-INCOME CONSUMER BEHAVIOR IN THE UNITED STATES

Background. Literacy relates to reading and writing skills, whereas numeracy relates to counting. Functional literacy relates to possessing the reading, writing, and counting skills to function in day-to-day life (Kirsch and Guthrie, 1997). Literacy and functional literacy are used interchangeably in this article. Low literacy, of course, is associated with low income as well, and the discussion emphasizes low-literate, low-income consumers in the United States, disentangling these two factors where possible. Literacy rates in the United States, until a few decades ago, were reported to be as high as 99%. However, such statistics were based on a question in the Census as to whether an individual was literate. Subsequently, when grade-equivalent tasks were used (e.g., if you are in a certain grade, you should be able to write a check or read a package label), the estimates of low literacy have varied from 20% to considerably higher. Statistics about literacy carry a sense of prestige with them and therefore, often reflect biases at individual and more aggregate state or country levels. The 2002 National Assessment of Adult Literacy (NAAL) showed that at least 22% of US consumers lack skills to perform retail tasks (e.g., calculating

unit prices and price discounts, comparing product attributes), and between 34% and 55% lack skills to look up reference materials to identify foods containing a particular vitamin (Kutner, Greenberg, and Baer, 2005).

Method. In describing literate versus low-literate consumers, it is important to understand that this is a continuum and that there is no demarcation that makes someone nonliterate, hence the preference here to use the term, low-literate. Also relevant here is how low-literate consumers can be studied. Experiments and surveys are not the most effective approaches, unless very carefully designed (Viswanathan, Gau, and Chaturvedi, 2008a). In this work, observations of classrooms at adult education centers, observations of shopping trips, and interviews of teachers and students were used. Typically, such centers have students divided by grade-equivalent levels, such as 0–4, 5–8, and 9–12, based on reading and math tests administered periodically, that is, ranging from low to moderate levels of literacy. Although a number of insights are offered below, it should be noted that some of them apply more to those at the 0–4 level than say those at the 5–8 level. Both vulnerabilities and strengths of low-literate consumers were observed in this work and that is important to acknowledge as well. Low-literate consumers overcome constraints borne out of their circumstances, sometimes in ingenious ways, and display extraordinary resilience in negotiating a marketplace that assumes a certain level of literacy. Over time, surveys and experiments have been employed as well.

Illustrative findings. In observations of low-literate consumers while shopping, most striking were the things that literate consumers may take for granted. A typical trip to the grocery store for a literate consumer may involve some trade-offs between price and attributes of products. If the intention is a cash purchase and one is short by a few dollars, it is usually not a big issue to leave behind some items and attribute things to one's forgetfulness. But this typical trip does not begin to describe the kinds of issues that take up much of the effort of low-literate shoppers, particularly those at the low end of the continuum.

2 consumer behavior across literacy and resource barriers

Locating a product can take considerable time, when reading signs is difficult or just not possible. Therefore, once a product is located, it may be bought. It is not always easy to be asking store employees for directions, particularly when an individual has spent a lifetime with low literacy and it has been cause for many travails. Identifying the correct volume can be effortful – finding 150 candles involves finding two different packets of a 100 and a 50. With the many different price tags and sales signs, finding the bottom-line price can be very confusing. Also, low-literate individuals may need to rely on written computations to find out the price of multiple units when the price of one is known. “% off” sales signs can be another cause for concern as some may completely avoid them owing to difficulty computing the final price or embarrassment with having to ask a store employee, whereas others may use them sometimes, say, when 50% off, as computing half off may be relatively easier. Computing the total on a shopping trip may be difficult, leading to solutions such as moving currency bills after each item is added to a cart or visually subtracting from an imagined set of currency bills. Similarly, allowing for taxes can be a significant concern leading to rules of thumb like buying one thing if one has five dollars. Unit prices are essentially abstractions that are difficult to understand and often ignored. Similarly, nutrient values may not be used and “% DVs,” serving sizes, and even expiry dates misunderstood or misused.

Adding to cognitive difficulties, issues such as being short of money at the checkout counter are cause for despair, as this is a result of one’s low literacy rather than forgetfulness. Similarly, having enough money can be cause for celebration. Underlying their shopping interactions for low-literate consumers is the need to maintain self-esteem and avoid being exposed for their low literacy. Thus, in addition to cognitive issues, emotional issues are also central, with anxiety being a common aspect of seemingly mundane shopping activities.

Cognitive tendencies. Some of these findings with cognitive tendencies, decision-making aspects, and coping strategies are summarized. A tendency that is most striking is one of concrete thinking, focusing on single pieces of

information such as price, without abstracting across, say price and size or price and other attributes (Viswanathan, Rosa, and Harris, 2005; Gau and Viswanathan, 2008). Buying the cheapest product without attention to size is an example of this tendency. It manifests in a number of ways, through seeking familiar stores, learning to use expiry date or other concrete information, such as numerical information, without understanding its meaning. In a study of low-literate peasants in Central Asia in the early 1900s, a Russian psychologist asked participants to view tools (e.g., an axe, a hatchet, a log, and a saw) and asked them to group three of these objects that can be described by a word or belong together (Luria, 1976). Participants responded in terms of how they could chop firewood to stay warm, that is, how they could use what they saw in day-to-day life. Thus, low literacy and difficulty with abstractions tends to lead consumers to think in the immediate, visual, graphic, here-and-now world of how they can use things.

Another cognitive tendency is pictographic thinking (Viswanathan *et al.*, 2005; Gau and Viswanathan, 2008). Although consumers in general depend on pictures, pictographic thinking is qualitatively different. It means viewing text such as brand names not as something to read but as an image, and thus remembering brands to buy through pictorial elements. Pictographic thinking also manifests in visualizing quantities to buy rather than using symbolic information. For instance, when buying an ingredient like sugar to bake a cake, low-literate consumers may visualize baking the cake and pouring sugar into it and buy the package of corresponding size. Pictographic thinking may even involve “counting” by visualizing currency bills. Pattern-matching prescriptions with medicine packages to find the right medicine is another approach. Whereas low-literate consumers may have poorer memory for textual information when compared to consumers with higher literacy, their memory for pictorial information, such as brand signatures, can be as good (Viswanathan *et al.*, 2009). Such improvement in memory appears to arise from familiar pictorial elements.

Decision making, emotional trade-offs, and coping strategies. Decision rules may range from single-attribute decisions (buy the cheapest) to habitual decision making or even random decision making (picking up the first item in a product category that is seen, for a planned or unplanned purchase). As noted earlier, sometimes, locating a product can lead to its purchase. This should be contrasted with conventional decision-making models, which cover a number of steps. Also intertwined with decisions are emotional trade-offs. For instance, low-literate consumers may trade off utility to save embarrassment, as maintaining self-esteem is central when they negotiate the marketplace. Having sufficient money at the counter may be cause for celebration, whereas being “caught” short may be cause for despair. The anxiety associated with negotiating a complex marketplace while lacking in literacy and trying to avoid being exposed on this account is the larger emotional context where day-to-day shopping occurs. Along similar lines, Adkins and Ozanne (2005) identify types of low-literate consumers on the basis of dimensions such as acceptance or rejection of stigma arising from low literacy. They find a number of coping strategies including avoidance, dependence on others, self-esteem maintenance, and social deception.

Low-literate consumers cope in a number of ways – depending on others, coming up with rudimentary defensive rules like buying one item from the menu at a time to avoid being short of money, and even giving all the money they have at the checkout counter. Some of the ways in which they cope are ingenious, such as in “counting” by visualizing currency bills. They often depend on others, sometimes even helpful store employees, to help them with shopping and avoid situations and stores that are likely to lead to embarrassment, striving to maintain self-esteem in their interactions.

Low-literate shopping behavior. A model of low-literate shopping behavior is presented in Figure 1 purely for illustrative purposes to contrast low-literate consumer behavior with more conventional consumer behavior. It should be noted that this model captures consumer behavior especially for 0-4 level adult education students, setting up a sharp

contrast with consumers with higher levels of literacy. In terms of generic models of decision making, low-literate consumers may bypass or spend minimal effort in steps such as prepurchase search and evaluation of alternatives. Alternatively, consumers bypass the entire decision process by mimicking others or by delegating responsibility to others. As indicated in the direct link from “need recognition” to “purchase,” some consumers may completely delegate decision making to others, highlighting the theme of dependence on others. The first step in the decision-making process is location of a product. Owing to the amount of effort expended in locating a product in the store, location may be followed by purchase. Location of a product may also be followed by obtaining the correct number of units of a product. Alternatively, the next step may be to expend effort in looking for a price, a distinct step in the process. The process may be “short-circuited” at this point by either reshelving or buying the product caused by lack of success in finding the price. The next step may be reading a price and iteratively looking for a price owing to confusion in identifying a price tag or interpreting multiple price stickers. Again, the process may be short-circuited through reshelving or purchase. The next step may be to locate the correct volume or number of units needed. In instances where a combination of package sizes are needed, significant effort may be needed in locating the correct packages. Location of needed volume may precede location of a price and reading a price, and may follow location of a product and may immediately lead to purchase. Location of volume may also be followed by looking for a price and/or reading a price. The next step is to compute a total price with some iteration needed here to perform the computations. Iterations may also be required here in looking for the price again or rereading the price, or identifying the correct volume. Reshelving or purchase culminates the decision-making sequence.

Although not strictly comparable to generic models of decision making and information processing adapted from the literature (Bettman, 1979), the shopping behavior model for functionally low-literate consumers highlights the importance of one or two stages in other models.

4 consumer behavior across literacy and resource barriers

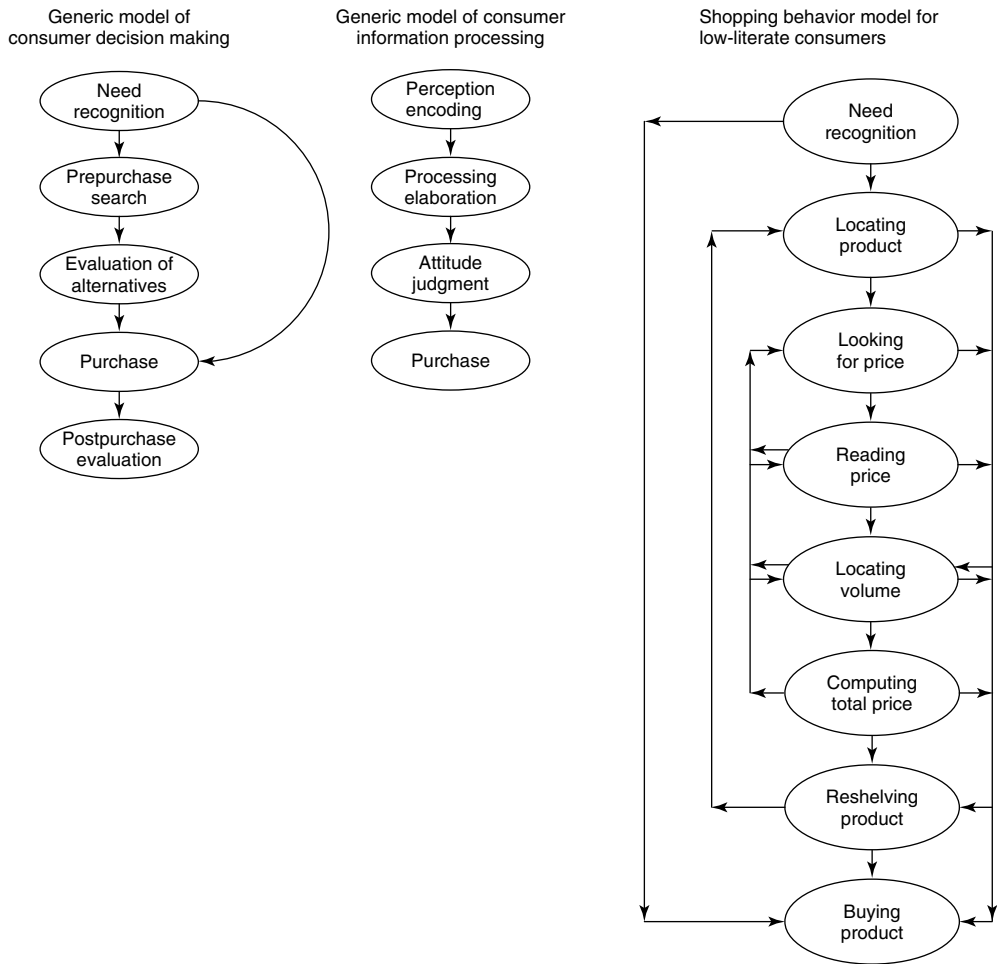

Figure 1 An illustration of shopping behavior for low-literate consumers.

In contrast to these typical decision-making and information processing models, the emphasis here is on perception of information, leading to surface-level processing of primarily one or very few pieces of product information (e.g., price information), often with error. Whereas typical information processing models include perception, encoding, elaboration, evaluation, and then purchase (Bettman, 1979), the emphasis for low-literate consumers is on perception with regard to location of product and identification of price. Encoding may be of a transient nature, with a view toward completing the immediate purchase task rather

than leading to memory and integration with prior knowledge.

Importantly, whereas this model may resemble low-involvement models of decision making and models of repeat purchase in terms of lack of active information seeking and lack of comparison along attributes (cf., Zaichkowsky, 1985), fundamental processing differences are noteworthy. The decision-making process involves bypassing of several steps when compared to traditional decision-making models. Rather than arising from a lack of motivation that characterizes low-involvement decision making and repeat purchases, this process can be quite

effortful. Thus, striking differences among consumers who differ in levels of literacy are illustrated by contrasting decision-making processes.

SUBSISTENCE CONSUMER BEHAVIOR

Background. The discussion now moves further across the resource spectrum to examine subsistence marketplaces and consumer behavior. Research in poverty contexts in India provides the foundation for the discussion. When compared to the United States, such contexts are characterized by more widespread poverty and higher rates of low literacy as well. Much of humanity lives on the equivalent of two to four dollars a day (Prahalad, 2005). However, much of what is known about consumer behavior has been based on studying relatively resource-rich, literate consumers, mostly in advanced economies.

Method. The work here was in low-income urban neighborhoods and rural areas in South India, using a range of methods including in-depth interviews of buyers and sellers (Viswanathan, 2007; Viswanathan, Gajendiran, and Venkatesan, 2008; Viswanathan, Rosa, and Ruth, 2010). Such subsistence communities are characterized by deprivation on many fronts. Uncertainty pervades every facet of life as basic infrastructure is either unreliable or absent. For example, rural areas are characterized by unreliable transportation or electricity. Central consumption events like cooking a staple, say rice, may be dependent on many factors – the quality of rice and water, availability of cooking fuel, and so on. There are, of course, many differences between urban and rural areas as well, with the latter having lack of access to markets and shops and more severe infrastructure problems.

Illustrative findings. In such marketplaces, subsistence consumers often have relationships with a single store, such as a neighborhood retail store that is conveniently located and charges higher prices but allows purchase on credit in times of need, or a larger reseller. Through such relationships, often with the neighborhood retail store owner, subsistence

consumers multiply the value of their patronage for a small seller and expect responsive customer service in return. It may be noted here that an understanding of relatively resource-rich settings may lead to misconceptions about subsistence consumer behavior. For instance, it may seem that buying from larger resellers at the beginning of the month and stocking up is the rational course of action. However, this implicitly assumes a stable income and the lack of frequent crises, certainties that are beyond the reach of subsistence consumers. Fear of crises necessitates buying on credit from the neighborhood retailer in exchange for consumer loyalty. Also interesting here is how the longer-term relationship rather than any transaction, and particularly an impersonal one, takes precedence as subsistence consumers and sellers leverage relationships to multiply the economic value and leverage social relations to compensate for the lack of marketplace infrastructure prevalent in resource-rich settings.

Subsistence consumers have to focus on products that serve immediate and basic needs, such as food and clothing, and emergency medical care. Their choices may be between buying a product, making it (e.g., indigenous soap substitute), or, of course, forgoing it. However, they aspire for quality brands that serve their needs and also for products such as cell phones that greatly improve their ability to communicate and can serve vital needs (e.g., for emergencies). They also aspire for a better future, making sacrifices to obtain better education or health care for their children – a driving motivation in many parents' lives. Subsistence consumers are also very adaptive and willing to experiment with new technology, such as cell phones, that serve vital communication needs. Their adaptivity is borne out by the need to survive and the experience of coping with extreme uncertainty in many realms of life that are taken for granted in relatively affluent settings. Thus, to fully understand subsistence consumer behavior, preconceptions that they require only some basic products or that products in demand would have to be of low technology need to be dispelled. Similarly, quality is very central, as scarce resources have to be used for products that will better subsistence consumers' immediate and basic life circumstances. Otherwise, subsistence consumers have

6 consumer behavior across literacy and resource barriers

the resilience to forgo products or the resourcefulness to make them.

The issues discussed for low literacy in the United States apply in subsistence marketplaces as well, in terms of concrete thinking and pictographic thinking. They engage in concrete thinking, such as in fixating on concrete numbers denoting price, such as maximum retail price, a requirement in the Indian marketplace. However, they may do so without understanding what it means. This is akin to low-literate consumers in the United States who may depend on expiry date without understanding its meaning. Pictographic thinking is also pervasive, such as in pattern-matching prescriptions with medicine labels. Self-esteem issues are also relevant, and although both poverty and low literacy is pervasive, the stigma attached to the latter is perhaps more acute, with lack of education often being attributed with the lack of ability to overcome poverty. Low literacy can lead to fear of conversations in shopping contexts, and feelings of futility about arguing with shopkeepers or questioning quality.

One-to-one interactional marketplaces. In a larger context of widespread and extreme poverty and low literacy, subsistence consumers negotiate the marketplace in ways that require face-to-face interactions and oral communication in the native language. Such communication does not require specific basic literacy skills, but rather knowledge of spoken language that individuals acquire growing up and social skills. Subsistence consumers can learn marketplace skills through conversations and observations on streets and other public locations. Conversations with sellers can lead to development of skills and self-confidence. Moreover, consumers themselves may often be vendors as a way to subsist and survive, thus learning valuable skills that transfer to their consumer behavior, such as negotiating, counting, and so forth. What is interesting here is the widespread existence of distinct markets in terms of the poor and the higher strata. Clothes can be purchased at department stores or on the sidewalk for diametrically opposite price points.

In this one-on-one interactional marketplace, subsistence consumers may be resource poor but network rich. With an opportunity to participate

through oral communications and observations, such a marketplace can be a stepping stone to gaining important skills, awareness of rights, and self-confidence. Word of mouth is powerful, and trust and fairness play important roles. With the life circumstances they face, the human aspects are intertwined with the economic as buyers and sellers negotiate while emphasizing both. Transactions can be fluid, with prices and amounts varied (e.g., weighing can be “adjusted” downward if the price bargained is too low) and buyers constantly demanding customization in offerings. As conversations are not private by and large and word can spread very quickly, sellers have to be careful about waiving payment or treating customers differentially.

This world of social relations also cuts both ways and should not be interpreted to suggest anything but an intensely harsh reality. For instance, noncollateral loan repayments are enforced through public humiliation and buyers and sellers are open to abuse and exploitation. Also relevant here are the many different group influences, whether local community groups or larger family or neighborhood or social strata. Group influences can be accentuated in rural areas where villages are geographically dispersed.

Contrasting low-literate consumer behavior in the United States to subsistence consumers in India. In comparing the two consumer groups discussed here, although speculative and cognizant of the wide range of differences within low-literate consumer behavior in the United States, say between urban and rural areas, and similarly in subsistence consumer behavior, a number of differences are noteworthy. In advanced economies like the United States, the marketplace context assumes a certain level of literacy. Large chain stores use technology to compute and present symbolic package and shelf information that assume a certain level of literacy. Thus, low-literate consumers may be isolated from the marketplace and the development of consumer skills may be impeded when compared to the one-to-one interactional subsistence marketplaces described here. In the latter context, generic products are evaluated in face-to-face interactions with prices determined by enquiry and bargaining, and money and

change counted out. Consumers learn skills by being vendors themselves and managing various aspects of a business, rather than through an occupation in a narrowly circumscribed role for a large business as may often be the case in advanced economies. Extreme poverty and the need to get the next meal is in itself a very harsh teacher of consumer lessons. Thus, ironically, the low-literate subsistence consumer may develop some of the functional skills needed to negotiate the one-to-one interactional marketplace, when compared to the low-literate consumer in the United States who has to negotiate a relatively impersonal marketplace that assumes a certain level of literacy.

IMPLICATIONS FOR MARKETING

Each of these streams of research across literacy and resource barriers suggest important implications for marketing. They also represent opportunities for marketers to serve these consumer groups effectively and gain a competitive advantage. Some generic implications that cut across both contexts are noteworthy. First and foremost is the need for literate managers and researchers to understand consumers whom they may not be able to personally relate to in terms of literacy or income. Thus, the most important implication is the need for literate, relatively resource-rich researchers and managers to adopt a mind-set of learning before designing solutions for these contexts. They need to understand consumer behavior in a realm where their own experiences as consumers, although a strength in understanding conventional consumer behavior, may be quite misleading. Thus, the need to employ innovative research methods to understand these consumer groups is critical. Conducting research in these settings requires setting aside preconceptions and employing an open approach that is conducive to learning from low-literate, low-income, or subsistence consumers. Instead of an approach that assumes literate managers and researchers know better and can design solutions for low-literate, low-income consumers or subsistence consumers, an approach of learning from those with experience and expertise in overcoming constraints and then designing solutions for them is likely to be effective.

Low-literate, low-income consumer behavior. A number of implications for marketing relate to addressing the cognitive predilections, emotional elements, decision making and coping discussed earlier (Viswanathan, Rosa, and Harris, 2005; Gau and Viswanathan, 2008). Marketers need to develop an understanding of the challenges faced by low-literate consumers and work to create shopping environments that are user friendly. Examples include price display and sale signs, the use of visuals (e.g., semicircles for half off, dollar bills for amount of savings) rather than abstract symbols such as percentages, and the display of final price, perhaps in a color-coded format, rather than having to rely on computations (Viswanathan, Rosa, and Ruth, 2008). The use of common formats to display information such as unit prices may enable low-literate consumers to inform themselves and begin to use such information to make price-size trade-offs. Pictographic representations such as heart signs or weighing machines as well as graphical representations of nutrient levels, instructions, and other pertinent information are other possible ways to design communications to enable usage by low-literate consumers. Store signs can similarly be designed to depict product categories pictorially and help consumers navigate the store. Familiar pictorial elements are a central means by which low-literate consumers may understand and remember information, therefore, the use of pictorial elements at the package, shelf, and store level are very important as well. Technological aids, such as shopping carts with scanning and computing features, would also be helpful to low-literate consumers as they keep track of their total shopping basket.

Perhaps most importantly, marketers should work to address the challenges faced by low-literate consumers that extend beyond the cognitive to the emotional as well. Training store employees to treat low-literate consumers sensitively and respectfully can go a long way toward building trust and, in turn, loyalty as well, and represents the essence of the marketing approach from which a sustainable competitive advantage can accrue. Perhaps most damaging is the perception among low-literate consumers that they are being cheated, emphasizing the need for employees to be trained and sensitized in these issues, while also distinguishing

between the consequences of low literacy versus other issues such as those faced by literate, English as second language consumers or by literate but poor consumers. Even if low-literate consumers do not complain, the lingering negative emotions may lead them to avoid future visits to such stores. Employees should be trained to interact with different consumers and to explain store policies clearly and respectfully.

At the level of product design, marketers need to learn to use innovative methods to research the needs of low-literate consumers and incorporate insights into the design of the product, including assembly and interface, as well as its packaging and related communications, such as instructions. This requires adopting a different mind-set than one that literate managers and researchers may typically employ, in order to view the usage of products from the perspective of low-literate consumers. A case in point is in designing the interface for computers and cell phones with visual icons, or the packaging of medical products with respect to dosage information.

A noteworthy issue is that many of these implications will ease shopping for all consumers, irrespective of literacy levels. Pictorial aids are easier to use for all consumers, as illustrated by such examples as displays of foods that specific wines can be served with. Product design that incorporates the perspective of low-literate consumers is similarly likely to enhance ease of use for all consumers. With the plethora of information at the store, simplified display of pricing and other information in consistent formats is likely to enhance the shopping experience for all consumers.

Subsistence consumers. Perhaps the biggest implication to marketers is to understand their own limitations in focusing on subsistence consumers owing to their likely lack of personal connection in terms of poverty, literacy, and culture (Viswanathan, Seth, Gau, and Chaturvedi, 2009). Thus, they need to unlearn preconceptions about these consumers and marketplaces and aim to understand their strengths and vulnerabilities as well as marketplace dynamics, such as between buyers and sellers. With an open mind-set and holistic immersion in the context during data collection

or a learning and listening phase, and rigorous consideration of what is different about these settings during analysis, marketers in turn, can bring a fresh perspective and new solutions that stem from deep understanding of a radically different context. Thus, complementary strengths and weaknesses that stem from being unfamiliar with subsistence marketplaces can be used to an advantage. Such immersion should aim to understand broader life circumstances and how products and related support would fit in such contexts and improve individual and community welfare. Critical here is the need to avoid exporting solutions from other markets.

Researching subsistence consumers, in turn, involves a number of cognitive, emotional, and administrative considerations (Viswanathan, Gau, and Chaturvedi, 2008). Marketers should gain insights from “experts” in living in subsistence ranging from consumers to vendors, self-help groups, and community-based organizations. Such bottom-up understanding is essential, given the vast differences across different subsistence contexts as a function of geographic location, local language, and cultural differences.

A fundamental challenge for marketers is to identify central needs that subsistence consumers are willing to spend very scarce resources on. Such needs range from the basic to the aspirational, often accompanied by a motivation to pay a small premium for quality – covering food, clothing, and energy, as well as health care, communication and education. In turn, designing solutions requires understanding broader life circumstances as well as specific product-usage situations, often difficult for affluent marketing managers and researchers. How subsistence consumers use or reuse products and use them for multiple purposes is also important to understand. Given the constant demand for customization in a one-to-one interactional marketplace, providing local entrepreneurs with the ability to configure products and prices to different customers is another important consideration (e.g., products with nutritional additives customized to different segments, such as children and the elderly). In designing solutions, the need to involve subsistence consumers and entrepreneurs is also

central, as is the need to address psychological aspects such as engendering trust.

In terms of marketing communications, including informational and educational campaigns, marketers should consider concretizing, localizing, and socializing solutions (Viswanathan, Sridharan, Gau, and Ritchie, 2009). Thus, information in concrete form for low-literate audiences who engage in concrete thinking and pictographic thinking, that also reflect local reality and harness the one-to-one interactional marketplace in terms of community interaction are all likely important elements of marketing communications. This is also the case for product interfaces and packages, with a need to visualize benefits and value propositions. In contexts of multifaceted deprivation, marketers should also consider product-relevant support including educational programs. Another important issue is the need to communicate the value proposition to highlight costs (e.g., including time and effort) and benefits (including hidden benefits such as nutrition to avoid illnesses) (Sridharan and Viswanathan, 2008). Such costs and benefits and the value proposition need to be communicated to low-literate audiences in ways that can be visualized. Communications should also be designed from the bottom up to harness the social networks discussed here, through partnerships with local entrepreneurs and customers. Similarly, distribution should harness social networks, such as through local retailers and community-based organizations and allow for customization at the point of purchase through such means as offering credit.

To implement their plans, marketers need to work with a diverse set of organizations who have been functioning in subsistence marketplaces, in a number of sectors of society, such as local governments and community-based organizations. Lacking the institutions in affluent markets that enable impersonal exchanges, relationships with diverse groups and organizations are critical in providing access and effectively implementing plans.

Marketers should also understand how product performance and related company activities work toward improving individual and community welfare (Viswanathan *et al.*, 2009). For instance, subsistence consumers seek

products that will better their life circumstances, ranging from nutritious food, to education for their children and communication devices. When products lack these characteristics, subsistence consumers may opt to make or forgo the products rather than spend scarce resources. Therefore, quality and value are extremely important. Moreover, product support through educational programs and other means may be critical in settings where deprivation is multifaceted. In their quest to survive, the human aspects and larger life circumstances are intertwined with economic transactions – in contrast to impersonal transactions in affluent societies with relative certainty regarding infrastructure and institutional support. Thus, issues of trust and fairness are very important and marketers should work to address them. With the one-to-one interactional marketplace described earlier characterized by strong word of mouth, a reputation for trustworthiness and fairness can go a long way in developing a sustainable competitive advantage. Focusing on individual and community welfare may also be helpful in working with diverse organizations to reach and serve markets.

In conclusion, the need to view subsistence consumers as preexisting marketplaces whose dynamics need to be understood by marketers should be emphasized. Rather than view these subsistence marketplaces as parallel markets to sell to, they should be viewed as marketplaces to learn from, to then design solutions for, that may well be transferable to all contexts. As a case in point, creating products for conditions of very scarce resources and lack of infrastructures, such as, say, distributed energy generators (solar applications), in turn has implications for all contexts in confronting the challenges of the twenty-first century.

In summary, a top-down approach to different elements of marketing assumes certain institutional infrastructure, often lacking in subsistence marketplaces. For instance, marketing research assumes the ability to sample, marketing communications assume mass media, and distribution assumes related infrastructure. With the lack of such infrastructure, subsistence marketplaces rely on social networks to provide some measure of certainty in an extremely uncertain world. Rather than adopt a mind-set of scaling by

using top-down approaches, marketers should employ a bottom-up approach to addressing each element of marketing in radically different and diverse subsistence contexts, and aggregate insights from the bottom up.

In conclusion, this article explored consumer behavior across literacy and resource barriers, in sharp contrast to conventional consumer behavior. Both for low-literate, low-income consumers in the United States, and for subsistence consumers in South India, traditional assumptions about consumer behavior do not hold. Rather, unique cognitive, emotional, and social characteristics that characterize such consumer behavior present marketers with challenges as well as opportunities to serve such consumers and develop a sustainable competitive advantage while also improving individual and community welfare.

emotion

Julie A. Ruth

OVERVIEW AND DEFINITION OF EMOTIONS IN CONSUMER BEHAVIOR

Emotions are psychological states of readiness that encompass thoughts, subjective feelings, physiological changes, expressive behaviors, and action tendencies (Bagozzi, Gopinath, and Nyer, 1999). The specific character of the subjective feeling – for example, love, pride, excitement, anxiety, fear, guilt, or anger – is associated with systematic patterns of appraisals the consumer makes about the event in the light of implications for well-being. In addition to appraisals, emotions have a felt, experiential component that is accompanied by physiological processes such as heightened arousal. Emotions are often communicated physically through gestures or facial expressions, allowing emotions to spread to others, and may result in the consumer taking specific actions to adapt to the situation at hand.

Consistent with approaches in psychology, consumer research distinguishes between emotions and related constructs such as affect and mood. Emotions typically have a target, such as the consumer being exposed to a TV ad that elicits guilt or a consumer experiencing anger in light of a provider's inept service delivery. In contrast, affect is conceptualized as a feeling state that is largely undifferentiated beyond its positive or negative valence, or as an umbrella term that encompasses a set of more specific feeling phenomena such as emotions, moods, and/or attitudes. Moods are conceptualized as lower in intensity than emotions and are less differentiated due to their lack of a specific target and lack of correspondence with specific appraisals and action tendencies (Bagozzi, Gopinath, and Nyer, 1999; Cohen, Pham, and Andrade, 2008).

Emotions can be experienced in anticipation of, during, or after consumption episodes such as fear in response to an ad identifying risks to family safety, delight and regret upon making a good or poor decision respectively, or anger when receiving poor or prejudiced customer service. Consumers can also experience a mix of emotions such as fear, joy, regret, and excitement in conjunction with skydiving or viewing horror

movies. Using frameworks of emotion developed in psychology as a foundation, Richins (1997) developed a set of descriptors reflecting the emotions consumers may experience when anticipating, acquiring, or possessing and using products. The Consumption Emotion Set (CES) includes multiple scale items associated with 16 emotions: anger, discontent, worry, sadness, fear, shame, envy, loneliness, romantic love, love, peacefulness, contentment, optimism, joy, excitement, and surprise. Richins also shows that consumers associate different emotions with different types of possessions. For example, sentimental objects such as heirlooms and mementos are associated with love, and recreational products such as stereo equipment are associated with positive emotions including excitement. In contrast, vehicles are associated with a combination of positive and negative emotions such as joy, pride, anger, excitement, worry, and guilt.

The next section describes the ways in which appraisals, coping, and goal striving are related to consumers' experience of emotions.

CONSUMERS' EXPERIENCE OF EMOTIONS

Appraisals. Emotions typically arise in conjunction with appraisals consumers make in situations of personal significance. Appraisals are evaluative judgments and interpretations of the meaning and importance of elements of the situation at hand. Appraisals may be conscious or may occur automatically upon perception. Johnson and Stewart (2005) synthesize appraisal theories drawn from psychology and suggest that six appraisals differentiate and inform the experience of discrete consumer emotions: (i) direction of goal congruence (i.e., positive or negative); (ii) agency, or the extent to which the locus of responsibility and control resides with the consumer, some other entity, or beyond anyone's responsibility and control; (iii) certainty; and (iv) normative or moral compatibility. In addition, appraisals of (v) goal importance and (vi) degree of goal congruence are linked to the intensity of emotional experience.

Different emotions are characterized by systematic patterns of appraisals. For example, as shown in research on gift exchange, gift recipients experience love in pleasant, goal-congruent

gift-exchange situations in which certainty and other-agency are relatively high and self-agency is low. In contrast, recipients experience anger in unpleasant, goal-incongruent exchange circumstances in which certainty and other-agency are high and self-agency is low. It is also important to note that, although there is evidence that appraisals can be causal in their influence on emotions, other mechanisms can elicit emotions. For example, noncognitive methods such as bodily feedback or unconscious priming have also been shown to elicit specific emotions.

Coping. Emotion regulation is aimed at coping with the implications of a given situation for the consumer and his or her goals and well-being (see MOTIVATION AND GOALS; CONSUMER WELL-BEING). Coping is the means by which an individual identifies and assesses the adaptive potential and significance of various actions. Of critical importance is the assessment the consumer makes in light of the actual situation compared to the desired one. Two appraisals are particularly important at this stage of emotion formation: goal relevance and goal congruence, or the extent to which the consumer perceives a personal stake in the situation at hand and the degree to which the event facilitates or inhibits this stake.

A prominent view suggests that two broad categories of coping strategies are available. Problem-focused coping aims at maintaining the original goal and taking action to attain the goal or maintain its achievement. Emotion-focused coping, on the other hand, involves an attempt to reframe the situation by shifting appraisal(s) and/or revising the goal. Such revisions in appraisal or goals shift the emotional reaction in light of the situation. For example, the angry consumer who lodges a complaint in order to resolve a negative situation may be activating problem-focused coping. In contrast, a consumer may be able to shift emotions from anger to disappointment through use of an emotion-focused coping strategy if he/she reframes the situation by strengthening beliefs that the service provider was not in control of a negative outcome.

Recent research shows that consumers frequently rely on both emotion-focused and problem-focused coping strategies and may do

so even within the same consumption episode. Further, some coping strategies may satisfy both emotion- and problem-focused coping goals. Duhachek (2005) reviews the psychological literature on coping and provides evidence for three broad categories of coping strategies used by consumers: (i) cognitive or behavioral (e.g., engaging in rational thinking about the situation, trying to make the best of the situation through positive thinking, or taking action to resolve the situation); (ii) expressive support seeking (e.g., engaging in emotional venting to others, seeking instrumental assistance from others, or seeking emotional support from others); and (iii) avoidance coping (e.g., avoiding the situation or denying it). Duhachek also shows that coping strategies are dependent on the specific emotion the consumer experiences and the consumer's beliefs about coping efficacy. For example, high self-efficacy consumers show a tendency to enact expressive support-seeking coping strategies when experiencing fear in contrast to active coping strategies when experiencing anger.

Goal striving and action tendencies. Closely related to coping is action tendency, which is a readiness to engage in or disengage from interaction with an object to bring the situation in line with goals. Anticipated emotions serve a role in goal striving through prompting intentions, plans, and decisions of how to allocate resources in order to move toward goal attainment (see MOTIVATION AND GOALS; CONSUMER INTENTIONS). Specific emotions also provide consumers with valuable feedback about their progress toward goal attainment. Happiness, for example, is perceived by consumers as a signal that a goal has been achieved, whereas sadness is a signal that goal achievement has not been attained.

Much as emotions arise in response to patterns of appraisals, there is evidence that patterns of action readiness also correspond with distinct emotions. Although positive (negative) consumption emotions may stimulate positive (negative) behavioral intentions, their shared valence is not the only factor that shapes behaviors. The nature of the consumer's goals also shapes action tendencies. Pride, for example, is associated with goal attainment, but it can occur in the light of achieving either

promotion or prevention self-regulatory goals. Research shows that consumers who experience pride in conjunction with prevention goals (e.g., striving to avoid paying extra money for a purchase) are less likely to repurchase than those with promotion goals (e.g., striving to obtain a discount as means to gain money), whereas there are no differences in repurchase behavior among consumers who experience low levels of pride in conjunction with either prevention or promotion goals.

THE ROLE OF EMOTION IN FOUR DOMAINS OF CONSUMER ACTIVITY

Emotions play important roles in many domains of consumer activity. Four key domains are consumer response to advertising, consumer decision making, purchase and service situations, and possession and usage.

Emotions and advertising persuasion. The majority of research on the role of emotion in advertising has focused on two aspects of persuasion: (i) the nature and effects of emotions evoked in response to ads; and (ii) how consumers process and evaluate ads that appeal on the basis of emotion (*see* ADVERTISING MESSAGE APPEALS; PERSUASION; ATTITUDES; ADVERTISING EFFECTIVENESS).

Ad-evoked feelings have been shown to systematically shape attitudes the consumer develops and holds toward the ad and brand. For example, Edell and Burke (1987) present a scale measuring emotional responses toward ads and find three factors underlying these responses: upbeat feelings such as delight, happiness, and pride; negative feelings such as anger and irritation; and warm feelings such as hope and having been moved by the ad. These positive and negative emotional responses to ads can co-occur and, along with cognitive responses, influence the formation of attitudes toward the ad and indirectly influence brand attitudes. Emotional responses to ads have been found to be more important determinants of attitude toward the ad than thoughts under low involvement conditions, whereas both cognitive and emotional responses are important under high involvement conditions.

Turning to consumer response to emotional appeals, these ads affect persuasion through

eliciting a sufficiently high level of emotion that attracts attention and prompts consumer processing of the message, which in turn contributes to behavioral intentions. For example, research has shown that negative emotional appeals can prompt positive outcomes, as when a negative emotional ad highlights the needs of abused children. These types of prosocial appeals elicit consumer feelings of sadness, anger, fear, and empathy. Stronger felt negative emotions tend to prompt greater feelings of empathy, which in turn facilitate intentions to help.

An inverted U-shaped pattern of effects of emotional appeals on persuasion is sometimes observed. In such instances, attitudes toward the ad and brand are relatively favorable under moderate levels of the elicited emotion and less favorable under either low or high levels of emotional response. For example, research shows that fear appeals that elicit low levels of the emotion are low in persuasion because they prompt insufficient elaboration of the threat or harm referred to in the ad. Likewise, appeals that elicit high levels of fear are also low in persuasion because they prompt an overly high level elaboration of the threat or harm that interferes with processing the recommendations for action to alleviate the fear. In contrast, appeals calibrated to elicit a moderate level of the emotion appear to strike an effective persuasive balance because the consumer is able to both elaborate on the threat and process the recommended action. Interventions that enhance the likelihood of elaboration, such as self-referencing, can increase persuasiveness of low-fear appeals, and elaboration-reducing interventions can likewise increase the persuasiveness of high-fear appeals (Keller and Block, 1995). Some research has also observed a similar pattern for appeals intended to elicit positive emotions, such as humorous appeals. Low levels of humor can be weak in attracting consumer attention, and very high levels of humor can distract the consumer from processing the marketing message. Moderate levels of positive emotion elicited through humor appears to strike an effective balance in attracting attention and prompting processing while leading to positive attitude formation.

Appraisal-related dimensions of emotional ads also influence persuasion. Whether an ad refers to high or low consumer agency, for example, shapes male consumers' attitudes toward the ad. Males form less favorable attitudes toward ads depicting a low self-agency emotion, such as peacefulness or tenderness, when viewing with another male. This result is attributed to the incongruence between the low-agency emotion and male stereotypes, which are made salient by the viewing circumstances. In contrast, ad attitudes are more favorable when males are exposed to either a low-self agency ad with a female viewing partner or when exposed under any viewing condition to an ad depicting a stereotype-congruent, high-agency emotion such as excitement or joy. Females do not display differential responses to high-versus low-agency emotional ads.

Members of different cultural groups may also process and evaluate emotion-based ads in systematically different ways. Consumers from collectivist cultures rather than individualistic ones have more favorable attitudes toward ego-focused (e.g., pride, happiness) versus other-focused (e.g., empathy, peacefulness) emotional appeals and brands. Consumers' motivation to process explains this somewhat counterintuitive pattern of results. That is, ads that are incongruent with cultural values are relatively novel and thus attention getting, which yields greater liking; ads that are easier to process because the appeals are consistent with cultural values are less novel and hence less attractive.

Some ads contain a mix of positive and negative emotional appeals, such as those combining happiness and sadness. Williams and Aaker (2002) find evidence that mixed appeals yield less favorable attitudes among consumers with a lower propensity to accept duality compared to those with a higher propensity, such as Anglo-Americans and Asian-Americans, respectively. Liking and recall of emotional ads tends to be higher among older compared to younger consumers. Further, ads focusing on avoiding negative emotions are liked and recalled more by older consumers and also younger consumers who hold a limited compared to longer time horizon.

Emotions and decision making. Emotions have been found to exert a variety of influences in consumer decision making through the signals they provide with respect to the consumer's movement toward goals and managing the situation at hand (see CONSUMER DECISION MAKING). Whereas considerable research examines ambient affect as a context effect (see Cohen, Pham, and Andrade, 2008), other research investigates a more central role of emotions in decision-making processes. According to an "affect-as-information" model, consumers may evaluate products by holding a target representation in mind and asking, "How do I feel about it?" From this theoretical perspective, consumers' emotions are considered to be valid sources of information.

When holding the target experience in mind, such as a consumer considering, "Should I go shopping this afternoon?", a target that elicits positive feelings leads to more favorable evaluations than a target that elicits negative emotions. The extent to which consumers rely on such feelings in decision making depends on (i) the heuristic value of feelings, (ii) their representativeness, and (iii) their perceived relevance (Pham, 1998). Specifically, feelings are more likely to be used when feelings have value as a type of heuristic, such as situations where few other sources of information are available or when feelings can be used to simplify the decision process. For example, the consumer may elect to eliminate from a choice set all alternatives that are not associated with positive feelings. Whether consumers rely on such feelings also depends on the extent to which feelings are believed to be representative of the target. Consumers are less likely to rely on them if they believe the feelings have not been elicited by the target itself, as when happiness is associated with the weather rather than the target consumption experience. Finally, consumers tend to rely on feelings when they are regarded as more relevant to the target, such as situations where consumers have experiential motives compared to instrumental ones. Consumers who tend to process in a sensory or visual manner also display a tendency to act in accordance with the affect-as-information framework.

While research has largely observed a carry-over effect of emotional valence on judgment and

choice, more recent studies argue that specific emotions give rise to specific cognitive and motivational processes that are systematically related to patterns of effects of emotions on decision making. Specifically, consumer emotions of the same valence, such as anger and sadness, can have different effects on judgment and choice because key appraisals and core experiential themes associated with them differ. Likewise, emotions of different valences may even have similar effects on judgments if they share other key appraisals and core themes.

Still, many choice decisions are in and of themselves difficult for consumers and elicit negative emotions. In their model of choice trade-off difficulty, Luce, Bettman, and Payne (2001) suggest that consumers appraise choice situations in light of goals and emotional content. They show that negative task-related emotions arising in situations involving difficult emotional trade-offs lead to various forms of coping that are either directed toward the problem or the emotion. If processing resources are limited, emotional reactions that are evoked spontaneously by an alternative in the choice set tend to have a greater impact on decision making and choice than cognitive reactions. In these constrained processing conditions, consumers tend to choose alternatives that are superior on an emotion-related rather than a cognitive dimension.

In contrast to trade-off difficulty, in other instances consumers may doubt whether what they yearn for is possible and thus find that their feelings of hope are threatened (de Mello, MacInnis, and Stewart, 2007). Consumers experience hope as a positive-valenced emotion that is elicited in situations that are uncertain but hold the possibility of achieving a goal-congruent outcome. If consumers lose confidence in a hoped-for outcome, they tend to engage in motivated reasoning when processing information about a product touted to enable goal achievement. That is, they tend to produce more self-serving product judgments, seek out product-supportive information sources, make biased assessments of information credibility, exhibit weaker distinctions between high- and low-credibility product information, and place less weight on negative information.

Kidwell, Hardesty, and Childers (2008) recently developed the Consumer Emotional Intelligence Scale (CEIS) to measure individual differences in consumers' ability to skillfully use emotion-based information in information processing and decision making (*see* CONSUMER INFORMATION PROCESSING; CONSUMER DECISION MAKING; EMOTIONAL INTELLIGENCE). The scale consists of items measuring four underlying dimensions of consumer emotional intelligence: *perceiving* emotions accurately; *facilitating*, or the ability to access and use emotions in mental processes; *understanding* emotions and their meaning; and *managing* emotions in the process of achieving desired outcomes. Consumers with higher compared to lower levels of emotional ability and confidence in this ability tend to make higher compared to lower quality choices.

Emotions arising in purchase and service settings.

Psychological aspects of emotions in purchase and service settings. Emotions that arise in product purchase or service delivery shape the consumer's assessments of satisfaction, complaint behavior, and word-of-mouth communications (*see* CONSUMER BEHAVIOR AND SERVICES MARKETING; CUSTOMER SATISFACTION). Research has largely found that the experience of positive emotions increases satisfaction while the experience of negative emotions decreases satisfaction, over and above the influence of expectations, product performance, and disconfirmation processes. Products that meet or exceed consumers' hedonic wants and fulfill promotion goals also tend to increase delight, which in turn contributes toward more favorable word-of-mouth and repurchase intentions.

Negative emotions arising from purchase have been the subject of numerous studies. Regret, for example, is experienced when the consumer makes the judgment that a foregone alternative performs better than the chosen alternative (Tsiros and Mittal, 2000). Consumer regret and satisfaction have been shown to have different antecedents, moderators, and consequences. Regret tends to be experienced when the consumer recognizes a better but forgone option and engages in counterfactual thinking in conjunction with a chosen outcome that is

negative and irreversible. Whereas regret and satisfaction both directly influence repurchase intentions, the influence of regret on complaint intentions is mediated by satisfaction. Although research has generally found that consumers experience more regret when deciding to make a change from the status quo compared to maintaining it, feelings of regret can be mitigated if the consumer reflects and concludes that the decision was appropriate under the circumstances.

There is evidence of systematic relations between appraisals, emotions, and the coping strategies that consumers employ in negative purchase situations. Yi and Baumgartner (2004) find that two dimensions explain the appraisal, emotion, and coping patterns of consumers experiencing anger, disappointment, regret, or worry in purchase: (i) the extent to which the consumer believes the problem can or cannot be managed; and (ii) the extent to which the consumer can manage or not manage the emotion itself. In anger experiences, where responsibility and control are attributed to another party and the situation is deemed changeable, a high problem-focus/low emotion-focus coping strategy of confrontation is likely to be used. In disappointing purchase situations associated with unmet expectations and a situation that is beyond the control of the consumer or other party, low problem-focus/low emotion-focus coping strategies such as disengagement are likely to be enacted. When consumers blame themselves and experience regret in purchase, they tend to engage in acceptance and positive reinterpretation coping strategies, which are low in problem-focus and high in emotion-focus. Worry, on the other hand, arises in consumption situations where the future is uncertain, and so a variety of coping strategies are enacted, depending on perceptions of control over the situation.

Numerous studies have also examined negative emotion experienced in service failures (see CONSUMER BEHAVIOR AND SERVICES MARKETING). Consumers make assessments about the characteristics of the failure, which are in turn associated with different emotions such as anger or regret. When consumers appraise a goal-incongruent situation as having been caused by the service provider, consistent with its characteristic appraisal and action

tendency patterns, the consumer is more likely to experience anger than regret and exhibit more retaliatory behaviors. Whereas marketers' recovery efforts that are designed to reduce consumer anger are associated with a reduction in consumers' retaliatory behavior, recovery efforts that aim to shift blame from the service provider to the consumer typically result in increased consumer anger and retaliatory behavior. Moreover, consumers' negative emotions such as anger or exasperation are highly predictive of their negative word-of-mouth behavior. Consumers' positive emotions, in contrast, are not related to their negative word-of-mouth behavior in these situations.

Social aspects of emotions in purchase and service settings. Many purchase and service contexts involve the presence of other people. How does that social situation affect consumer emotions? How is the consumer affected by another person and that individual's emotional state? Some research argues that emotional contagion occurs when one person "catches" the emotion being experienced and expressed by another person, so that the emotion of the receiver converges with that of the sender. Recent findings suggest that the role played by an emotion sender – a fellow consumer versus an employee – and the authenticity of the sender's emotional display influence how the emotional message is received by consumers. For example, Howard and Gengler (2001) find that emotional contagion occurs when happiness transfers from senders to receiving consumers who have positive relational bonds with senders. The facial expression of senders must be visible in order for receiving consumers to mimic the smiling and experience the happy emotion, which in turn has a positive impact on receivers' attitudes toward products that are present in the situation. Research on employee–customer interactions shows that employees' emotional displays can also trigger changes in customers' emotions but that, in addition to the bond established between employees and customers, the correspondence in employee/customer emotions may depend on the authenticity of employees' emotional display rather than the mere act of smiling itself.

Consumer emotions are also affected by brief interactions with unacquainted others or even a noninteractive “mere” presence of others in a shopping environment. Dahl, Honea, and Manchanda (2005) show that consumers who interact briefly with a salesperson compared to those who do not are more likely to experience guilt if they do not ultimately make a product purchase. Consumers are also more likely to experience embarrassment in purchasing an embarrassing product in the presence of another. Several other factors affect the degree to which consumers experience embarrassment in purchasing embarrassing products: the frequency of the potentially embarrassing situation’s occurrence, the severity of the social threat, and the consumer’s public self-consciousness. Likewise, the presence or absence of others can affect the experience of anger in service failure situations. Consistent with research on the salience of felt ethnicity in numerical minority social conditions, Baker, Meyer, and Johnson (2008) find that service failures elicit higher levels of anger among black consumers when no other black customers are present compared to situations where several other black consumers are present, or compared to white consumers in either condition.

Emotions arising in possession and usage. Studies examining various aspects of possession and usage have found emotions to be central to these experiences in two noteworthy ways. First, mixed emotions are common because consumption experiences almost always involve multiple and sometimes conflicting attributes and goals. Second, possession and usage contexts are often social in nature, and so interpersonal and social factors may be more salient in the experience and effects of emotions in these types of consumption settings.

The recent work on indulgent consumption acknowledges the importance of positive and negative emotions, showing that their effects are dependent on the specific combination of mixed emotions that consumers experience. With indulgent consumption, both prudent and impulsive consumers experience a mix of positive and negative emotions such as excitement and frustration. Yet prudent, but not

impulsive, consumers also tend to experience negative self-conscious emotions such as guilt and shame. As time elapses after indulging, impulsive consumers are more likely to feel residual effects of their positive emotions as their negative feelings dissipate, whereas negative emotions including self-conscious feelings tend to persist for prudent consumers while their positive emotions dissipate. As a result, prudent compared to impulsive consumers are less likely to indulge when given a subsequent opportunity to do so (see IMPULSIVE AND COMPULSIVE BUYING).

The nature of emotions experienced in consumption also affects memory, where mixed consumption experiences involving both positive and negative emotions are more difficult to recall accurately than unipolar ones. In addition, over time consumers remember mixed emotion experiences as less mixed, a finding that highlights a type of memory decay that does not occur with unipolar emotion experiences. The felt conflict of mixed emotions appears to explain this decay. The memory bias is also more evident among Anglo-American compared to Asian-American consumers, consistent with other research regarding cultural differences regarding acceptance of duality.

At first glance, consumers’ pursuit of consumption experiences laden with negative emotions, such as horror movies, would seem to be counterintuitive. Research shows that viewing horror movies elicits both negative and positive emotions in consumers predisposed to viewing horror movies. In contrast, only negative emotions are activated among consumers who typically avoid these types of consumption activities. Although similarly high levels of negative emotions are felt by both types of individuals, consumers with a protective orientation that provides psychological distance or detachment are able to experience positive emotions as well (see Cohen, Pham, and Andrade, 2008).

Turning to social aspects of consumption, some research has examined the correspondence between the emotions consumers experience and the relationships they hold with others including family, friends, and acquaintances. For example, gift exchange oftentimes elicits a mix of emotions, such as joy and love in being acknowledged as a gift recipient but

also the anxiety a recipient may experience in being the center of attention and obligated to conform to dramatic scripts associated with rituals like baby showers or holiday observances. As a result, valence alone does not explain the relationship impact of gift exchange. For example, research shows that gift recipients who perceive that the relationship with the giver is strengthened typically feel a mix of positive and negative emotions such as joy in the relationship heading in a desired direction but fear of the unknown that lies ahead in the relationship. Recipients who believe already-strong relationships are affirmed typically experience positive emotions in gift-exchange processes (Ruth, Otnes, and Brunel, 1999).

With a focus on participation in rituals, Otnes, Lowrey, and Shrum (1997) explore the nature of consumer ambivalence, defined as the simultaneous or sequential experience of multiple emotional states that are shaped by the consumer's interaction with social or cultural phenomena in market-oriented contexts and that influence prepurchase, purchase, or postpurchase attitudes and behavior. Four antecedents of consumer ambivalence emerge in their study of consumer participation in wedding planning: a gap between expectations and actual experience, overload in decision-making processes, role conflict with others, and conflicts among customs and/or values. These antecedents are associated with specific coping strategies that consumers use to manage their ambivalent feelings such as striving to assertively resolve gaps between expectations and reality regarding products or retailer services, or compromising to deal with role conflicts.

LOOKING FORWARD

Much of the extant research in our field has adopted a psychological perspective, concerned with the individual consumer's experience of emotion and its effect on other individual-level phenomena such as the consumer's attitudes, choices, assessments of satisfaction, and goals (see ATTITUDES; CONSUMER DECISION MAKING; CUSTOMER SATISFACTION; MOTIVATION AND GOALS). Yet, it is important to note that consumer

behavior frequently occurs within interactions with service providers, friends, family, and even strangers in servicescapes and shopping environments. Building on extant research with a psychological foundation, recent studies of the social aspects (see SOCIAL INFLUENCE) of emotional experience and expression provide a strong platform for expanding research on how consumer emotions are elicited and shared between and among consumers and marketing agents such as service providers and sales personnel. Such initiatives could address how such emotions affect interpersonal phenomena, for instance, assessments of interpersonal relationship quality, trust, and commitment.

Such initiatives could also contribute to our understanding of how consumer emotions contribute to and shape the meanings and emotional attachments consumers have with brands and BRAND COMMUNITY, the ways in which consumers experience and express nostalgia, and other emotion-based aspects of possession and usage. In addition, recent conceptualizations emphasizing the perspective that emotions are informative and help consumers to function and adapt to changing situations provide promising directions for new knowledge insights on emotions in consumer behavior.

consumer behavior and services marketing

Dawn Iacobucci

INTRODUCTION

Let us take a simple consumer behavior process and see how it is studied and modified by services marketing scholars. In particular, let us begin with the basic, vanilla-flavored consumption model, in which a consumer (i) identifies some desire, (ii) searches for means of satisfying that desire, (iii) makes a choice and a purchase, and (iv) afterward reflects upon that purchase. This article elaborates on the stages of this process with an eye toward identifying the special concerns of the services marketing researcher.

WHAT IS SERVICE MARKETING?

Presumably, the reader of this volume will walk away with a strong and clear understanding and appreciation of the explication of the consumption process. What is new to this article is the twist on services. Hence, a starting point is to clarify what is meant by services marketing. While the phrase *services marketing* is rather general, it tends to mean one of two things: a researcher is studying either customer service or some consumption phenomenon in a service industry.

The breadth of services marketing is part of what makes teaching services fun because the cases and applications run the gamut from customer service in, say, an automobile dealership, where the focus of the purchase is a good, or a call center, where the focus is often on service recovery, to fairly routine and familiar services such as hotels and restaurants, to the more sophisticated services such as in the health care or legal professions.

The range of applicability can be explained in part from the philosophy that just about every purchase contains some element of service. In the early days, services marketing scholars made a point of distinguishing services (e.g., dry cleaning) from goods (e.g., shampoo) to highlight the conceptual differences worthy of study. Contemporary thinking is that very few things exist that have not been processed in

some manner (e.g., perhaps coal or wheat), and that the value-added processing is itself service. This argument of the pervasiveness of services seems to be getting more difficult to challenge as so much of the value-added element is information-based, both in B2C and B2B markets.

WHAT IS DIFFERENT ABOUT SERVICES?

There are several dimensions along which services have been distinguished from goods, or along which the service element of a purchase can be distinguished from whatever goods might be transacted in the purchase. The acronym “SHIP” is helpful to remember the primary dimensions: the “S” stands for “simultaneity of production and consumption,” the “H” for “heterogeneity,” the “I” for “intangibility,” and the “P” for “perishability.” Let us break these down, and then examine how each impacts the consumption process.

Simultaneity: Services are simultaneously produced and consumed. For example, a masseur creates an experience as the consumer experiences it. Massages are not stored in a spa, waiting to be pulled off a shelf when a customer buys one. The interaction between the service provider and the client is key to the service being customized and therefore optimally pleasing to the customer. The fact that services unfold in real time has several implications for the consumption process, as discussed below.

Heterogeneity: Services are also said to be heterogeneous. The idea is that one customer’s experience is likely to differ from that of another. One person may rave about a masseuse, whereas another might find that provider’s techniques too light or too deep, and he/she may not leave the spa as satisfied as the first customer. This type of difference is due to customer variability; on a large scale, we would call these segment preference differences. Other differences are attributable to the service providers having different styles and talents. Still other sources of variability are more temporary—a customer or service

provider may be in a bad mood, and have an “off” day. As these examples illustrate, heterogeneity in customer experiences is largely attributable to the service encounter being an interpersonal interaction. Marketing managers responsible for services have a much greater challenge than those overseeing goods; people are harder to manage than machines. We will see shortly how marketers try to compensate in the consumption process.

Intangibility: Services are also said to be more intangible than goods. A 17-year-old girl who bought the book *Twilight* has a tangible proof of purchase. Another, who went to see the movie, has no visible evidence of the movie experience, except, perhaps, for swoony eyes. Many purchases are of course a mix of the tangible and intangible. Imagine an evening dining out—there exists both the tangible (food, restaurant appearance) and the intangible (attentiveness of the wait-staff, ambience). Most people’s largest purchases—a house and a car—include the physical purchase of the dwelling or the vehicle, as well as less-tangible elements, such as financing, insurance, and maintenance. For those two purchases, the tangible might seem to dominate the intangible. For another large household purchase, a kid’s education, the intangible seems to dominate the tangible. These examples notwithstanding, expensive purchases are not always those dominated by goods—divorces are services and they are also expensive. Health care is a service and it can be costly. We now discuss what marketers make of intangibility.

Perishability: The final piece of the SHIP acronym is perishability, and this aspect of services derives in part from the first, the simultaneity of production and consumption. The potential service provision during lull times cannot be realized during peak times; it has perished. For example, the airplane leaves the ground with some empty seats that can never be regained, or a tax consultant’s hours during a slow month cannot be recaptured in early April. Now let us blend these service dimensions with the consumption process.

WHAT ARE THE IMPLICATIONS FOR THE CONSUMPTION PROCESS?

In this section, we take the properties of simultaneity, heterogeneity, intangibility, and perishability and consider their effects on the service encounter. Recall the basic consumer behavior process: needs identification, information search, choice and purchase, and postpurchase reflection. We will treat the process in temporal order.

Needs Identification. While some services require special skills (e.g., tax attorney, psychiatrist), there are many services that customers can provide for themselves, should they choose to do so (e.g., lawn-mowing, ride to the airport). When customers choose to outsource and buy a service, there must be a reason why paying another to execute the service is superior to doing it oneself. The trade-off is usually some combination of time, expertise, and convenience. For example, most of us could mow our lawns, if we wanted to: we would start up a mower, push the machine back and forth, and so on. However, most of us are busy enough that we would assess a trade-off of time and value, and conclude that it is worth it to hire someone to take care of the landscaping.

Yet while it is true that we seem to be getting busier and busier, there is a seemingly counter trend, and that is the growth of self-services (Meuter *et al.*, 2005). Many grocery chains offer self-service checkouts. At the outset, checking oneself out might seem to take more time than letting someone else scan the items, but when the lines for the checkers are long, the same principle of time-famine motivates customers to do the work themselves—it is faster. There is no price discount (or premium) for self-checkout. There are also no superior skills required of the checker than the customer. Hence, the self-service checkout is altogether more convenient.

As the effects of information technology seem omnipresent, here too, smart software can begin to simulate the expertise that a regular customer lacks and who would have traditionally sought a professional. There are a variety of software packages that facilitate our lives: some prompt us to calculate proper taxes, others assist in writing wills, other software functions as a dietitian, and still other programs serve as tutors when learning foreign languages.

The challenge in the future will be to determine those purchases for which we will continue to buy a service provider's time and expertise, and those for which we will enjoy the consumption of the activity itself. Marketers for service providers will have the challenge of demonstrating even greater value in the time and money saved, and the additional expertise and value-added elements that the service provider may bring to the customer.

Information Search. For reasons that will become clear shortly, services marketers have always made much of the expectations that customers hold when they enter the service encounter. Marketers try to shape expectations through various communications, for example, advertising, public relations, and information posted online. Yet unlike shopping for a laptop or automobile, where we might seek comparisons among brands as conducted and reported by experts, a good part of services are experiential. That services are experiential is attributable in part to the intangibility quality, an essence that is difficult for an expert to convey.

The challenge to marketers is to take the intangibility, which is difficult to grasp by customers because it is abstract and ethereal, and make it more concrete. As a result, marketers are encouraged to use symbols in their advertising and logos to express their benefits more tangibly (e.g., "You're in 'good hands' with AllState"; "Like a 'good neighbor,' State Farm is there"). The abstraction also leads customers to believe that the purchase might be somewhat risky, as they do not know quite what to expect. Accordingly, some marketers have demonstrated success in showing customers videos that preview the service they are about to experience so as to help them understand more precisely what to expect (Bitner *et al.*, 1997).

Customers who have experience with a particular service provider will naturally have information from which they derive expectations for future interactions. Lacking direct experience, customers are thought to rely on word-of-mouth from trusted sources, such as friends or coworkers. Indeed, services marketers have long posited the very likely greater importance of word-of-mouth for services than for the purchase of goods. As online social networks thrive, we can expect this

form of tailored communication to only grow in strength. Marketers have not yet come upon the winning formula for monetizing a presence in such spaces, but with time, no doubt, will do so.

Another prepurchase phenomenon in services that receives much consideration is queuing, the one tool in a marketer's arsenal that approximates the inventorying of goods. While a movie theater might not be able to seat more than 200 patrons on a Friday night for an opening of some new, wildly anticipated movie, it can encourage moviegoers to attend at another showing, by making another time slot more desirable, such as by lowering prices. Restaurants similarly take reservations to try to manage fluctuating demand. Yield management is a near science at the airlines, though not without error, as overbooking experiences will attest. In fact, marketers look to levers such as price to increase or decrease demand, so as to more optimally match supply, in the provision of many kinds of services (Desiraju and Shugan, 1999).

Choice and Purchase. The purchase of a service is far more complicated than the purchase of most goods. The complications are first due to the heterogeneity, due to the fact that the service encounter is frequently an interaction between two people, the customer and service provider, both of whom can introduce noise or error into the system. There is not much that a marketer can do to control the behavior of a customer, but the behavior of the front-line employee serving that customer leads marketing to a nexus with human relations. To ensure smooth service encounters, marketers have emphasized the importance of supervisors and companies being selective in hiring service providers and in training them (Heskett, Sasser, and Schlesinger, 1997), empowering them (Schneider and Bowen, 1995), and keeping them motivated (Rust and Chung, 2006).

The complications of services marketing purchases are also due to the aspect of services being simultaneously produced and consumed. One implication of the fact that services unfold in real time is that the customer's evaluation of the service—the service experience, the front-line service provider, or the service firm brand—is comprised of many "moments of truth" (Carlzon, 1989). All these elements, whether large and central (e.g., a dental exam),

or smaller and seemingly peripheral (e.g., the availability of parking near the dentist's office), factor into the customer's overall assessment of the service encounter. To manage the multitude of process issues, services marketers have encouraged the use of flow charts to explicate the consumer experience down to the last detail, as well as the behind-the-scenes operational elements which facilitate a smooth customer service flow (Lovelock and Wirtz, 2006; Fisk, Grove, and John, 2007; Bitner, Ostrom, and Morgan, 2008). Note too that the real-time process can be potentially advantageous – it can allow for the customization of the transaction for superior service, or for the recovery of impending service failure for at least minimally acceptable levels of service quality.

As brand building is all the rage, it is important to see the implications of the heterogeneity and simultaneity on this marketing effort. It is difficult to build a brand, much less an excellent brand, when it is difficult to assure the consistency of the quality of the purchase experience. In services marketing, one form of brand building is the distribution channel of the franchise system. In franchising, the attempt is to sell a service system that is as standardized, replicable, and as consistent as possible. Some succeed – those with a large portion of tangible character (e.g., some hotel or restaurant chains), or with heavy assistance of information technology (e.g., tax assistance offices). However, while brand building might be an admirable goal for such straightforward services, it would likely be more difficult to brand a professional service. In the professions, one touts the reputation, that is, the brand, and hopes that all the service providers deliver at the heights implied and expected. If the members of the profession have been hired selectively and well trained, perhaps the service can be seamless and of consistently high quality.

Postpurchase Reflection. Services marketing adheres rather uniformly to the model known variously as the *disconfirmation paradigm* of customer satisfaction or the *gap model* of service quality (Oliver, 2009; Zeithaml, Parasuraman, and Berry, 2009). In this model, a customer is thought to come to the service encounter with certain expectations, and judges the quality of the encounter against those expectations. If the

customer's expectations are met, it is predicted that the customer is satisfied. If the experience is much better than the expectations, it is predicted that the customer is delighted. If the experience does not hold to the expectations, the customer is expected to be dissatisfied.

It is in this evaluative phase that we see why marketers pay attention to expectations. Some admonish to “manage expectations” (downward), so that the service provider can meet or exceed them. However, downward management is counter to the marketing impulse of bragging in advertising.

The comparative judgment model got attention very early as services marketers struggled with the implications of services being intangible, and therefore quality being difficult, or at least subjective to evaluate. Marketers overseeing goods of many kinds, from consumer packaged goods to electronics to durables, rode a wave in the 1980s of total quality management, which specified, among other things, accuracies in processes and outcomes. Manufacturers of corn flakes can say they want 10 ounces of flakes per box, and if they set their machinery properly, that is what they will get. Marketers responsible for a high quality service encounter struggle with such standards. What should be measured and managed that serve as cues to good quality? In the late 1990s, many companies would brag, “We answer our customer service calls within three rings,” which of course begs the question, “What is the quality of the customer service provided once the phone is picked up?” As a result, the evaluation of customer satisfaction or service quality remains largely subjective, perhaps as it should be, if we marketers truly believe customers should have the last word.

As the consumption process of the service encounter is extended over time, it is natural to take the evaluation and generalize it as well. Loyalty systems thrive in services, at least in those sectors where switching costs are not high. Whether it is a free coffee for every 10th purchase, upgrades for sufficient air miles, shorter queuing systems for preferred insurance packages, or discounts for the use of retail cards, services marketers have embraced loyalty programs. In turn, when the resulting information capture is used creatively, true customer relationship management can further enhance

the customer's share of heart and wallet dedicated to the particular service provider.

CONCLUSION

Consumers are not thought of as behaving all that differently in a service encounter compared to how they behave when purchasing a good. However, the service encounter itself is a more complicated purchase. Accordingly, as the services marketing literature matured, the research and writings gave opportunity to reflect on new issues.

As stated at the outset, most purchases have some element of goods and some element of services transacted. The question is a matter of the proportions of each. As a result, the theories and research findings of the services marketing scholars are relevant and very broadly applicable.

consumer aspects of international marketing

Claudiu V. Dimofte

THE GLOBAL CONSUMER

The globalization of markets has long defined the research agenda of economists and marketers alike. Yet the perspective that each group tends to employ when approaching the topic varies to a large extent: the former are mostly concerned with the international flows of capital, labor, and goods that imply a large degree of cross-market homogeneity, whereas the latter generally assume cultural heterogeneity and look for locally defined cultural determinants of consumption behavior. On the one hand, marketplace evidence suggests that specific consumption patterns across the globe do show some convergence, such that market segments from culturally and geographically distant nations are developing similar tastes and product preferences. This phenomenon is at the core of what GLOBAL MARKETING STRATEGY has termed the *universal segment* (or *intermarket*) approach to market segmentation: positioning the firm's offerings toward groups of consumers around the world who display similar needs and look for the same product benefits, regardless of location (see Toyota Scion vehicles and MTV programming targeting Generation Y consumers internationally). Furthermore, the ubiquity of the Internet at the center of many nations' social and technological environments allows marketing information to easily diffuse and spill over, to create more uniform consumer knowledge and interests, and to generate relatively consistent brand preferences across borders, as the law of communicating vessels would predict.

On the other hand, the alternative view to this single world economy is the perception of multiple world markets, each described by idiosyncrasies that are deeply rooted in cultural heritage, as determined by local knowledge, beliefs, customs, and so forth. Global marketing textbooks provide a multitude of approaches for segmenting such markets, under the implicit assumption that attempting to standardize one product across national boundaries described by so much cultural variance is practically impossible. For anyone who has ever traveled

to a foreign land and has experienced the at once wonder and shock associated with dramatically different people, foods, or customs (ever had a balut egg in the Philippines or exchanged business cards in Japan?), this perspective has immediate resonance. To better understand what global consumers may be about and how marketers can appropriately describe and predict their behavior, it is useful to begin by addressing the topic of consumer culture (see SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE) in more detail.

Consumer culture. Defining the *culture* construct is no easy theoretical endeavor (see SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE). In short, culture consists of a society's complex set of beliefs, customs, and other specific forces that shape individuals' perceptions and behaviors and is thought to be a key characteristic of a national environment that produces systematic differences in behavior across borders (Steenkamp, 2001). Whereas some have suggested that clusters of countries may display numerous cultural commonalities and could thus be construed as regional metacultures (Steenkamp, 2001), dealing with the idiosyncrasies of national cultures is a more intriguing conceptual endeavor. Looking for the dimensions underlying cultural specificity has thus been the main concern of cross-cultural research, in an attempt to bring some uniformity and measurement structure to a highly diverse global environment.

The earliest and arguably the most influential account of cultural variation and its impact on business is that of Hofstede (1980). His framework discusses five dimensions: individualism/collectivism (addressing the individual vs group relationships), power distance (looking at power inequality in terms of hierarchical social layers), masculinity/femininity (dealing with the social implications of gender, such as a focus on success vs quality of life), uncertainty avoidance (handling economic and social uncertainty), and long-term orientation (displaying a cognitive focus on short- vs long-term temporal horizons). The empirical study underlying his research was highly comprehensive and robust, employing over 60 000 respondents across 70 countries. Each of these nations was assigned an index on

2 consumer aspects of international marketing

each dimension, which was then linked with a variety of societal variables (geo-demographics, political, economical, etc.) – an operationalization that no other research has matched.

Relative to other frameworks, Hofstede's (1980) work displays high relevance to a variety of global business contexts (including international marketing), while maintaining a high level of conceptual convergent validity. That said, Schwartz (1994) provides an alternative perspective that – unlike Hofstede's (1980) focus on social dimensions – takes a more individual-level look at specific cultural values. Within a comparably large sample (over 60 000 respondents across 64 nations), Schwartz (1994) uncovers seven universally relevant cultural domains: harmony, egalitarianism, intellectual autonomy, affective autonomy, mastery, hierarchy, and embeddedness. Owing to their complementarity, combining the Hofstede (1980) and Schwartz (1994) frameworks has been suggested as a way to uncover clusters of more manageable regional cultures of interest to marketers (Steenkamp, 2001).

The immediate practical relevance of the cultural specificity that these frameworks address for the marketing efforts of any firm can be observed even within the confines of a particular nation, as in the proverbial cultural melting pot represented by the United States. Simply thinking about the different consumption patterns that the various US ethnic groups display can easily illustrate this point. Reading the grocery shopping lists of families of consumers in the African-American, Hispanic, or Asian ethnic groups will probably reveal very different items, flavors, and quantities. And watching television programming (as well as the associated advertising) on NBC relative to Telefutera or the BET channel will most likely entail highly distinct experiences. The existence of these microcultures (Steenkamp, 2001) contoured along ethnic or other dimensions highlights the importance of studying cultural heterogeneity through a more fine-tuned lens.

Another relevant stream of research addresses what social psychologists have termed individual difference variables describing consumers. In an international marketing context, one must be aware of a variety of social or subjective

norms that influence how consumers in a nation perceive or respond to (products from) specific countries (home or foreign). For example, some consumers display a tendency to denigrate foreign products and favor domestic ones, a behavior that renders them ethnocentric with respect to foreign products (see *BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS*). A related construct is that of *CONSUMER ANIMOSITY*, such as that describing reactions of some American consumers to French-made products after this nation's opposition to the 2003 invasion of Iraq (remember those *freedom fries*?). On the opposite end of the spectrum, there are individuals who show a consistent interest in other cultures and global issues or even preference for foreign products. These consumers are generally considered high on worldmindedness (see *CONSUMER WORLD-MINDEDNESS*), affinity (see *CONSUMER AFFINITY CONSTRUCT*), or cosmopolitanism.

If cultural and even individual differences are so prevalent both across nations and within them, what is left of the claim that today's consumer is a global consumer? Keillor, D'Amico and Horton (2001) undertook survey research with consumer samples from the United States, France, and Malaysia to assess the extent to which individuals with such culturally and economically distinct backgrounds would display similar tendencies related to specific aspects of the psychology of consumption. When juxtaposed across four relevant constructs (i.e., national identity, ethnocentrism, social-desirability bias, and response to consumer influence sources), the differences were not remarkable, suggesting that consumers around the globe may indeed become more homogenous in terms of their consumption behaviors. Nevertheless, although a global consumer may be emerging, cultural differences across nations are still highly relevant to international marketing researchers. The next section provides specific considerations in support of this point.

International marketing research. One of the classic debates in the academic field in terms of dealing with the cultural differences that underlie the consumption behavior of

individuals across nations is that between the *emic* and *etic* perspectives. Paralleling the earlier idiosyncratic-generic dichotomy related to the globalization of consumers and consumption patterns, this debate refers to the choice of theoretical frameworks to be employed in examining cultural differences. The *emic* view argues that such frameworks need to be culture-specific and operationalized via indigenous research techniques and instruments. Alternatively, the *etic* perspective favors the use of already established, universal theoretical frameworks as benchmarks for research pursued in any specific culture (Maheswaran and Shavitt, 2000).¹ A specific charge levied against the latter approach is that too often this established framework is developed by US researchers who simply attempt to apply it in novel cultural contexts, with little adaptation (Sekaran, 1983; Steenkamp, 2001). A potential solution to the *emic-etic* debate was proposed by Douglas and Craig (2006) in the shape of two iterative research approaches: the *adapted etic* (i.e., explicitly adapting the conceptual model of a base culture to the differences of new research contexts) and the *linked emic* model (i.e., taking the local context as the simultaneous starting point, at multiple research sites).

A related concern for international marketing researchers (academics and practitioners alike) is that of achieving measurement equivalence when it comes to employing specific scales in cross-cultural contexts. Therefore, it is important that not only conceptual equivalence of the target construct(s) be ensured (in particular within an *emic* theoretical approach) but that instrument equivalence (e.g., in terms of the item and scalar properties of the measure) be achieved as well (Maheswaran and Shavitt, 2000). In terms of construct operationalizations, method and item bias are often a concern in multicountry marketing research, as are the choice and relevance of the particular unit of analysis employed (Douglas and Craig, 2006). Finally, cross-cultural research is also affected by more practical methodological problems, such as the sampling, timing, and specific choice of statistical analyses underlying data collection and study across nations (Sekaran, 1983).

It should be noted that the field of international marketing is a broad one and includes

theoretical accounts from multiple disciplines. Whereas the focus of this article is on consumer-level variables that borrow conceptually from social and cognitive psychology, there are complementary perspectives such as the theory of the international firm (e.g., global marketing strategy, *see* GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES, and the management of international operations) and the economics of global markets (e.g., international pricing, *see* INTERNATIONAL PRICING OBJECTIVES AND STRATEGIES, and distribution INTERNATIONAL MARKETING CHANNELS) which require similar concern with conceptualization, operationalization, and measurement. The next section bridges the global consumer-global firm dyad by addressing recent literature findings on consumer response to global brands (*see* GLOBAL BRANDING: THREE KEYS FOR GLOBAL BRAND SUCCESS).

CONSUMER RESPONSE TO GLOBAL BRANDS

As is the case with the *culture* construct, there is also considerable ambivalence in the international marketing literature in terms of what a *global brand* actually represents. Much of the practitioner view on the issue is simply limited to the international, multimarket reach and profit potential that a brand accrues. For example, the Interbrand agency – which compiles its annual top 100 brands list for publication in Business Week – looks in its valuation at a brand's future earnings potential, with the expectation that a certain percentage of its sales come from each market in which it operates. The rival Millward Brown agency and its similar rankings published in the Financial Times require that a brand be present in at least seven countries before it is deemed global; yet by its own admission only 3% of its more than 10 000-brand database achieve this standard.

In terms of the academic research on the topic, the problem of operationalization may be one reason for the lack of a universally accepted definition of the global brand. However, the dimensions that underlie the global brand construct have been researched in a handful of articles, including Dimofte, Johansson and Ronkainen's (2008) work that identified five

4 consumer aspects of international marketing

latent factors: *reach, aspiration, low risk, ethics, and standardization*. The authors show that consumers perceive global brands to be widely available, well recognized, standardized, more powerful, more cosmopolitan, and subject to more stringent social responsibility standards than other, more local brands. However, other brand attributes such as higher quality are – perhaps somewhat surprisingly – not necessarily associated *a priori* with global brands.

Combining the practitioner and academic perspectives may bring into focus a clearer, albeit still imperfect, understanding of what the global brand is about. Thus, as far as consumers, brand managers, and most academics are concerned, a global brand has a strong presence across multiple national markets, which associates it with universal recognition, the promise of long-term financial survival, and the burden of higher social responsibility standards governing its corporate behavior. Yet, the largely positive image inherent to this global brand definition is not universal. Literature suggests that there are important differences in terms of the specific valence that these defining global brand attributes acquire for consumers in the developing versus the developed world. Simply put, whereas the former aspire to the idealistic qualities embodied by a global brand, the latter are significantly less impressed. The next section addresses this dichotomy in more detail.

Global brands in developing versus developed nations. Alden, Steenkamp and Batra (1999) argue that globally positioned brands might work better in markets that are characterized by lower levels of economic development, since “consumers in these markets may admire the ‘economic center’ and believe that [. . .] ownership of brands from the West increases the owner’s status” (Alden, Steenkamp and Batra, 1999, p. 84). Subsequent work by Batra *et al.* (2000) finds similar evidence that consumers in developing nations perceive nonlocal brands as preferable to local brands.

Holt, Quelch and Taylor (2004) uncover four basic dimensions of global brands *quality signal, global myth, social responsibility, and American values*. Averaging across responses from 12 countries (including the United States), their results

also suggest that developing nations consumers aspire to the greater global community and in the process downgrade their own brands relative to global brands.

While the evidence of the attractiveness that global brands entail for consumers in developing nations is consistent in the international marketing literature, things are less clear cut when it comes to consumers in developed nations. On the one hand, Steenkamp, Batra and Alden (2003) investigate US and Korean samples and find that perceived globality positively impacts both perceived brand quality and prestige, including in the United States. On the other hand, Johansson and Ronkainen (2005) analyze the top 150 brands in terms of brand strength from the large cross-country and multiyear database underlying Landor’s Brand Asset Valuator (BAV) model. In a survey of these brands across eight developed countries, the authors find that although global brands are held in high esteem, they are not necessarily associated with high levels of quality or other desirable brand attributes. There is also some evidence suggesting that local brands still command deeper customer loyalty than global brands in developed countries. For example, empirical analyses of Young & Rubicam data on brands from the European marketplace show that in such mature markets local brands often do better with consumers than global brands.

To understand this international dichotomy of responses to global brands, Dimofte, Johansson and Bagozzi (2010) evaluate ethnic consumer groups in the United States. Reflecting the aspirational dimension inherent to global brands for consumers in developed nations, the historically more economically disadvantaged African-American and Hispanic market segments are shown to associate global brands with higher product quality, more social status and prestige, as well as superior style. Yet, Caucasian consumers do not find global brands to be any more exciting than other brands, and – although they do perceive them to imply higher social status – they do not think their product quality is necessarily higher, mimicking the findings in developed nations (Dimofte, Johansson and Bagozzi, 2010). However, as a conceptual check, the relationships in a structural equation model show similarity across

ethnic groups in the way the global brand associations link up to consumer attitudes and purchase behavior. Those with more positive perceptions of global brands also have more positive attitudes overall and, as one would expect, show higher purchase rates of global brands. Although Caucasians' perceptions and attitudes tend to be less favorable than those of African-American and Hispanic consumers, they nonetheless buy global brands at the same rate as non-Caucasians (Dimofte, Johansson and Bagozzi, 2010).

Other global branding research findings. The extensive literature on global branding cannot truly be done justice within the limiting confines of a short article, so the final part of this section presents selected findings on the topic from two lines of consumer research – both classic (the country-of-origin effect) and more recent (automatic consumer response to global brands).

A firm's marketing communications, strategic marketplace behavior, and perceived competitive performance create in consumers' minds a particular brand personality and a variety of related brand associations – in short, (*see PERCEPTION OF BRAND EQUITY*). One of these brand associations that is particularly relevant to international marketing researchers involves consumer perceptions of a brand's country of origin (*see "COUNTRY OF ORIGIN" AS BRAND ELEMENT*). The location where a product is made prompts immediate country associations (i.e., a particular country image) that consumers generally incorporate into their brand evaluations and oftentimes produce cognitive biases in terms of attitudes and choice. Consumers tend to evaluate products more favorably when they originate in countries that benefit from a positive image (i.e., stereotypical perceptions describing the likely quality and performance of locally made products).² Most of us would likely agree that given a choice and in the absence of price constraints we would prefer a Swiss watch, a French perfume, or a German car. At the same time, similar negative stereotypical perceptions (created or reinforced by significant press coverage) have recently produced an avoidance behavior among many consumers toward products originating in China.

The country-of-origin effect is robust enough to emerge in studies that employ single-cue and multiple-cue product stimuli, within and between-subjects designs, and US and non-US samples. There have been two major cognitive process explanations proposed to underlie this effect. Depending on a consumer's familiarity with a country's products, country image can operate as either an inferential halo or a summary construct. If a consumer is unfamiliar, country image is used as a halo that impacts attribute ratings and, indirectly, brand attitudes (e.g., for Korean automobiles, quality inferences are made based on one's perception of Korean-made things in general). If the consumer is familiar with the country's products, the country image becomes a summarizing construct for the product attributes, directly influencing brand attitudes (e.g., for Japanese electronics, the fact that they are made in Japan is a proxy for high quality).

An interesting cognitive bias related to the country-of-origin effect is presented by Leclerc, Schmitt and Dubé (1994) in their research on consumer response to brand names that merely suggest a specific national origin. The authors show that product evaluations change such that, for example, more hedonic perceptions follow a French pronunciation relative to an English one for the very same brand name (Leclerc, Schmitt and Dubé, 1994). The fact that merely altering the pronunciation produces biased perceptions of brand attributes (as mediated by country-of-origin inferences) attests to the strength and ubiquity of the effect in daily consumption. This is an important finding, because other research has shown that a product's country of origin heightens or lowers relevant consumer expectations (depending on the direction of the associated country stereotype), with direct implications for subsequent evaluative standards and customer satisfaction (*see CUSTOMER SATISFACTION/DISSATISFACTION*).

Despite the fact that the country-of-origin effect has been widely demonstrated, consumers' reliance on country image when forming attitudes and making choices is generally not acknowledged in self-reports. It has also been shown that country stereotypes can be spontaneously activated by the mere contextual

presence of country-of-origin information, with subsequent measurable impact on attribute and product evaluations without consumers' intention or control. A similar finding in terms of American consumers' response to global brands shows that they explicitly deny the importance of brand globality in choice, yet clearly favor them in terms of subsequent behavioral measures (Dimofte, Johansson and Ronkainen, 2008).

The lack of acknowledgement in self-reports could have two possible explanations. On the one hand, it may simply be a matter of conscious self-presentation bias, driven by a strategic desire to appear open-minded and sophisticated when responding to international marketing surveys. On the other hand, it may be that consumers are truly unaware of the biases they hold, and as such unconsciously rely on information such as a brand's country of origin or global nature to inform their subsequent judgments (*see IMPLICIT CONSUMER COGNITION*). To evaluate these alternative explanations in the case of global brands, Dimofte, Johansson and Ronkainen (2008) employed the Implicit Association Test (IAT).³ The results showed that, compared to local brands, global brands were more closely associated with adjectives such as *ideal* and *desirable*, whereas local brands, by contrast, were seen as more concrete and mundane. The IAT responses did not correlate with self-reported explicit attitudes toward global brands, such that even consumers who were explicitly against globality displayed the same implicit preference for these brands.

CONCLUSIONS

The emergence of global consumption patterns and, at the same time, the complexity involved in understanding the still remaining national differences attest to the importance of research in international marketing. As reviewed in this article, the field is indissolubly linked to the topic of cross-cultural consumer behavior and its applications.

When considering the relevant conceptual and theoretical perspectives employed in research in international marketing, the emic-etic juxtaposition should be carefully assessed in order

to ensure the validity of subsequent findings and their relevance to corporate strategy. At the same time, when thinking about the practical aspects of assessing and satisfying consumer needs across the globe, issues such as the appropriate operationalization of constructs and the achievement of measurement equivalence across multinational samples should be at the center of international marketing research. Yet, despite these cross-national cultural differences, a global consumer culture may be emerging, and the field seems well positioned to address it.

Finally, the extensive literature on relevant topics such as the country-of-origin effect and global branding is informative to both academics and practitioners in suggesting that, despite local specifics, the global consumers' behavior is governed by universal social-psychological processes and cognitive biases. Understanding these underlying factors will leave both consumers and firms better off.

ENDNOTES

¹ Others have argued that the international marketing field may benefit from employing established theoretical frameworks that originate in other academic areas.

² The level of fit between particular products and countries of origin underlies the product ethnicity construct (*see PRODUCT ETHNICITY*).

³ The IAT is designed to measure the strength of automatic associations between mental representations of concepts in memory. It requires the rapid categorization of various stimulus objects, such that easier pairings (i.e., faster response latencies) are interpreted as being more strongly associated in memory than more difficult pairings (i.e., slower response latencies).

consumers' need for uniqueness

Ayalla A. Ruvio

Consumers often use possessions to differentiate themselves from other consumers. This tendency of using possessions to project a unique identity has been conceptualized as consumers' need for uniqueness (CNFU). The theoretical basis of CNFU is rooted in the more general theory of the need for uniqueness (NFU), which focuses on people's perceptions of and reactions to their similarity to others (Snyder and Fromkin, 1980). NFU theory postulates that individuals continuously evaluate their degree of similarity or dissimilarity to others and act on such evaluations. Individuals will normally attempt to maintain moderate uniqueness from others and will actively avoid being too similar or too different from others. High levels of similarity or dissimilarity will result in unpleasant feelings, reducing the individuals' self-esteem (Fromkin, 1972), and will trigger emotional and behavioral reactions. However, the magnitude of such reactions will vary across individuals and situations and will be determined by the individuals' level of NFU. The stronger it is, the greater the individuals' sensitivity to similarity and the more different from others they will want to be (Fromkin, 1972). However, the desire for uniqueness does not ignore social norms and is constrained by the need for social assimilation and approval (Snyder and Fromkin, 1980).

Building on the notion that possessions are an extension of one's POSSESSIONS AND SELF, CNFU reflects the individual's propensity for acquiring, using, and disposing of possessions in order to construct and maintain a unique self and social image (Tian, Bearden and Hunter, 2001). Tian, Bearden and Hunter (2001) conceptualized CNFU as a behavioral construct with three facets. Creative choice counterconformity captures the individual's tendency to use socially acceptable products and brands in order to create a distinct personal image (Snyder and Fromkin, 1980). Unpopular choice counterconformity postulates that individuals who seek to differentiate themselves from others may do so by using products that are not entirely within group norms, and will risk social disapproval (Tian, Bearden and

Hunter 2001). Finally, avoidance of similarity reflects the individual's intentional avoidance of popular and commonly used products and brands. Such individuals lose interest in, avoid purchasing, or discontinue using those brands when they become commonplace (Tian, Bearden and Hunter, 2001). Tian and her colleagues (2001) developed a 31-item scale to measure the enduring trait of CNFU. A shorter 12-item version was later validated by Ruvio, Shoham and Makovec-Brencic (2008) in different cultural settings.

Empirical studies established that individuals will tend to display their uniqueness more in identity-relevant domains and in situations that pose a threat to their sense of distinctiveness (Berger and Heath, 2007). CNFU was also found to be related to a variety of consumption behaviors such as shopping innovativeness (*see* CONSUMER INNOVATIVENESS), opinion leadership and market mavenism, optimum stimulation level, status consumption, individualism, choice of shopping venues, preferences for unique exterior product design, and preferences for scarce and customized products (e.g. Clark and Goldsmith, 2005; Ruvio, Shoham and Makovec-Brencic, 2008; Tian, Bearden and Hunter, 2001).

integrated marketing communication

Philip J. Kitchen and Inga Burgmann

INTRODUCTION

Integrated marketing communication (IMC) emerged during the late twentieth century and its importance has been growing ever since (Grove, Carlson, and Dorsch, 2002; Cornelissen, 2001; Hartley and Pickton, 1999). Owing to the impact of information technology, changes came about in the domains of marketing and marketing communications which led to the emergence of IMC (Kitchen *et al.*, 2004a; Phelps and Johnson, 1996; Duncan and Everett, 1993). The multiplication of media, demassification of consumer markets, and the value of the Internet in today's society are just three of the areas in which technological innovation has impacted (Pilotta *et al.*, 2004; Peltier, Schibrowsky, and Schultz, 2003; Reid, 2003; Lawrence, Garber, and Dotson, 2002; Fill, 2001; Low, 2000; Hutton, 1996). This in turn left marketers in a challenging and competitive environment, trying to fulfil customers wants and needs while also developing long-term relationships with them. IMC can help in creating coordinated and consistent messages across various channels of communication. Furthermore, the concept is especially valuable in that it places great emphasis on the importance of all stakeholder groups and, in particular, on customer loyalty, which can only be created through strategic relationship building (Jin, 2003/2004; Cornelissen, 2000; Eagle and Kitchen, 2000; Pickton and Hartley, 1998; Miller and Rose, 1994).

To date, academic research on IMC has been limited. The majority of empirical research has been conducted with advertising and PR agencies or companies located in the United States with a clear tendency toward quantitative methodologies (Jin, 2003/2004; Peltier, Schibrowsky, and Schultz, 2003; Kitchen and Schultz, 1999; Beard, 1996; Miller and Rose, 1994). Very few studies have concentrated on the business "client" perspectives within Europe (Cornelissen and Thorpe, 2001; Low, 2000; Kitchen and Schultz, 1999).

The following sections discuss IMC in greater depth. Firstly, the relevance of IMC as a concept

is discussed. Subsequently, an analysis of IMC implementation is carried out with reference to past research. Then, barriers to integration and criticisms of IMC are addressed. Finally, concluding comments are proffered.

THE IMPORTANCE OF IMC

This section focuses on the importance of IMC. First, the evolution of IMC and different IMC definitions are reviewed. A contemporary perspective on IMC is offered with a subsection flagging up the benefits of such an approach. Lastly, IMC's impact on promotional mix elements is presented.

The evolution of IMC. Integration, the attempt to present a consistent message across the available promotional mix elements has always been important to successful organizations even during the mid twentieth century. With the multiplication of media channels in the late twentieth and early twenty-first century, the integration and coordination of different messages aiming to portray a single and unique image to all stakeholder groups has become both more important and more difficult to achieve.

However, some researchers believe that the concept of IMC can be traced back to the 1970s (Cornelissen and Lock, 2000; van Riel, 1995). The first study on IMC was conducted by Caywood, Schultz, and Wang (1991b) at the end of the 1980s, while the first "conceptual ideas" were published in the book "Integrated Marketing Communications" by Schultz, Tannenbaum, and Lauterborn (1993). IMC advocates believe that its emergence was down to the context of media upheaval of that time, for example, digital TV and mobile phones, market environments, that is, increasing global competition and rapid technological developments, such as the personal computer (Kliatchko, 2005; Reid, 2003; Eagle and Kitchen, 2000; Griffin and Pasadeos, 1998; Bruhn, 1997/1998; Hutton, 1996).

Technology can affect IMC from two sides, that is, from the marketing and consumer perspectives (Kitchen *et al.*, 2004a; Schultz, 1993f). Today, integration is needed owing to globalization and the resulting interdependence between countries and marketplaces (Kitchen

2 integrated marketing communication

et al., 2004a; Schultz, 1996b). Thus, corporate and brand managers need to coordinate the actions of their global and even national brand(s) with the aim of integrating elements of promotional mix.

A global marketplace which becomes more transitory through the Internet may lead to a customer-driven and focused marketing environment. In such an environment, technology can enhance marketing communication strategies, that is, both traditional advertising techniques and also new, unconventional marketing practices may be applied, such as database marketing, one-to-one communication, or marketing PR (McGrath, 2005a; Edelman, 2004; Gonring, 1994; Nowak and Phelps, 1994). The social networking website MySpace, for example, has more than 17 million visitors each month in the United States. Marketing communication innovators propose the exploitation of such networks as a means of establishing an ongoing dialogue with customers and prospects (Economist, 2006a). In conclusion, not only can technology help consumers to connect and communicate with each other but it can also act as a facilitator in establishing a relationship with individual consumers and companies.

Owing to disagreements about the emergence of IMC and the limited amount of research conducted with actual organizations, researchers have thus far been unable to agree upon a single definition of IMC. Kliatchko (2005), though, has examined the various definitions of IMC that have emerged over time and tried to explore their dimensions in the hope of unifying them. Table 1 is based on Kliatchko's (2005: 21) table of IMC definitions. So, his own definition and another recent definition by Schultz (2004b) have also been added.

As demonstrated in Table 1, during the early 1990s IMC was referred to as the *one sight, one sound or one voice* or the *seamless marketing communication* approach (Beard, 1997; Nowak and Phelps, 1994; Duncan and Everett, 1993). However, the increasing interest in the subject of IMC led researchers to reevaluate the concept and the "buzz words" were soon set aside (Grove, Carlson, and Dorsch, 2002; Lee, 2002; Fill, 2001; Hartley and Pickton, 1999; Phelps and Johnson, 1996). These words only hinted at the many applications of IMC

and, therefore, new concepts were added to the earlier definitions of IMC.

Contrary to the implication of many of these "buzz words," IMC does not mean that an organization should only work with one message or with a single unifying brand. Rather, an integrated approach encourages managers to work with multiple targets and enables them to achieve integration of different brands, communication messages, and functions within one company. Thus, IMC has the potential to fundamentally change the meaning of marketing communications and may even be the next step in the evolution of marketing (Dewhirst and Davis, 2005; Kliatchko, 2005; Grove, Carlson, and Dorsch, 2002; Lee, 2002; Phelps and Johnson, 1996).

As in an early definition by Caywood, Schultz, and Wang (1991b) (see below), for many practitioners and researchers, IMC is a concept which strengthens the effects of promotional mix elements at the tactical level, if these elements are united (Schultz, 2006a; Cook, 2004; Naik and Raman, 2003; Fill, 2001; Cornelissen and Lock, 2000).

[IMC is a] concept of marketing communications planning that recognizes the added value of a comprehensive plan that evaluates the strategic roles of a variety of communication disciplines – general advertising, direct response, sales promotion, and public relations – and combines these disciplines to provide clarity, consistency, and maximum communication impact (Caywood, Schultz, and Wang, 1991b: 2-3).

However, more recent definitions, such as the one presented by Schultz (2004a), add substantial value to old definitions and to the term IMC more generally. The concept is now viewed as a strategic instrument (Schultz, 2004b: 9).

IMC is the concept and process of strategically managing audience-focused, channel-centered, and result-driven brand communication programs over time (Kliatchko, 2005: 21).

The new definition seems more appropriate to the twenty-first century, as Schultz acknowledges IMC's importance as a business process and its value to both external and internal audiences. The definition provided by Schultz

Table 1 IMC definitions.

| <i>Author and Year</i> | <i>Concepts Introduced</i> |
|--|--|
| Caywood, Schultz, and Wang (1991) and Caywood, Schultz, and Wang (1991b) | <ul style="list-style-type: none">• Coordination and consistency of messages and communication channels (one sight, one sound)• Use of a variety of communication disciplines to work in synergy based on a comprehensive plan• IMC as a concept |
| Schultz (1991) | <ul style="list-style-type: none">• Inclusion of consumers, prospects• Behavioral responses• Nurture relationship and customer loyalty• IMC as a process |
| Duncan and Everett (1993) | <ul style="list-style-type: none">• Profitable relationships expanded audience scope from customers to other stakeholders |
| Nowak and Phelps (1994) | <ul style="list-style-type: none">• Reinforced notions of consistency, coordination, and behavioral response |

| Schultz (2004b) and American Marketing Association (2007) | <ul style="list-style-type: none">• Strategic business process• Extensive brand communication• Evaluation and measurement• External and internal stakeholder groups• Long-term brand value focus |
| Kliatchko (2005) | <ul style="list-style-type: none">• Process and concept• Audience-focused• Communication program• Result-driven |

Source adapted from Kliatchko (2005: 21)

(2004b) has also been used by the American Marketing Association to define integrated brand communication (American Marketing Association, 2007). However, Kliatchko (2005) does not focus explicitly on individual stakeholder groups but rather refers to them as “audiences.” In addition, his definition is not as explanatory in nature as Schultz’s (2004b), as he underplays the results-driven characteristic of IMC and does not explicitly mention the importance of the long-term brand value and short-term financial returns. As noted by Kliatchko (2005); Schultz’s (2004b) definition supplements other IMC definitions through its employment of the terms

“business process,” “evaluation,” and “measurability”.

Many researchers have noted that it may not be possible to agree upon a universal IMC definition, given the various interpretations of IMC and its different values in the academic and commercial spheres (Kliatchko, 2005; Phelps and Johnson, 1996; Stewart, 1996). A critical review of previous definitions of IMC and an assessment of current IMC literature reveals that researchers were able to reduce any IMC definition to five crucial attributes (Kitchen *et al.*, 2004a; Low, 2000):

4 integrated marketing communication

1. The communication effort should be directed at consumers in order to affect behavior.
2. An outside-in approach should be utilized, that is, start with the customer first when developing a communication strategy.
3. A well-established relationship between the company and the customer is necessary.
4. To deliver a message correctly all communication activities should be included with contact points integrated into the strategy.
5. To create a competitive brand, coordination between the communication disciplines is needed.

A contemporary perspective of IMC. Owing to the rising demand in various product categories after World War II, the focus of marketers shifted to the product itself, making potential relationships with customers something of a side issue (Johnson and Schultz, 2004; Kitchen, 1999; Evans and Berman, 1987). During the 1950s, most organizations arranged their plans in line with their products and not according to customer wants and needs (Johnson and Schultz, 2004). Fuelled by dramatic changes in the marketplace and communications, retailers and other intermediaries have since gained in importance (Rosenbloom, 2004; Low and Mohr, 1999; Schultz, 1996b).

With competition increasing and with supply outstripping demand in most developed countries, a shift in power towards retailers and intermediaries has occurred. For this reason, building a long-term relationship with customers should be important to any kind of business in today's marketplace. Indeed, owing to the direct contact that retailers have with the end-consumers of manufactured goods, they should also know them better. Indeed, a powerful relationship exists between retailers, intermediaries, and manufacturers. (Reid, 2003; Low and Mohr, 1999; Schultz, 1996b). In an ideal world, the relationship between retailer, intermediary, and manufacturer would be interdependent, if not to say integrated, so that all parties could create customer-orientated communication messages, and essentially so that the manufacturer could develop customer-specific products (Pickton and Broderick, 2005; Schultz and Schultz, 2003; Schultz, 1993c).

Communication between customer and manufacturer used to be linear or one-way, that is, from the marketer to the consumer (Schultz, 1993c). But the customer of today has knowledge about the marketplace and has no need to wait for messages and information from the organization. The customer of today makes informed decisions and will make demands and influence advertisements or any other information received. Marketers must respond to these changes. The marketer needs to develop communication plans with the consumer as the starting point, later working back toward the product or service in order to design effective communication strategies. During the planning process, information about the customers, their wants and needs, and other background knowledge must be obtained. In IMC taxonomy, this is known as an *outside-in* approach (Kitchen, 2005; Schultz and Schultz, 2003; Hartley and Pickton, 1999; Schultz, 1996b; Stewart, 1996; Schultz, 1993e, 1993c). An important outcome of an IMC approach is that all communication mix tools, at least on the company's side, are integrated and support each other, resulting in synergy effects.

Another major driving force behind IMC is the demassification of markets. Many mass markets of the twentieth century have separated into diverse and smaller markets splintering into more specific customer segments. As a result, individual consumers' lifestyles, income classes, education, gender, and consumer actions characterize these new markets. The rich information flow from the Internet, broadcast media, and the press make information available to the consumer as never before, but research has discovered that most customers make their purchase decisions based on information of perceived value and not based only on the information a company chooses to present to them. Therefore, the ability of a company to utilize an outside-in approach and to portray a consistent image to prospects and existing customer groups becomes a critical success factor in competitive and information-rich market places (Jin, 2003/2004; Fill, 2001; Gould, Lerman, and Grein, 1999; Pickton and Hartley, 1998; Herrington and Lollar, 1996; Stewart, 1996; Schultz, Tannenbaum, and Lauterborn, 1993).

Benefits of IMC. IMC enables marketers to combine all of their communications in order to plan and create a coherent and synergistic approach. An important benefit of IMC is that it appreciates the significance to marketing strategy and corporate branding of new communication tools, such as direct marketing, Internet marketing, or different types of sales promotions (McGrath, 2005b; Pickton and Hartley, 1998; Drobis, 1997/1998).

Central to the discussion of contact points and message integration is the idea of incorporating different communication disciplines into one marketing communication campaign with the aim of achieving outcomes desirable to the company, for example, persuading customers to buy. As most organizations need to communicate with more than one target audience or stakeholder group, any campaign should take the characteristics of both the product brand and the corporate brand into consideration (Gylling and Lindberg-Repo, 2006; Phelps and Johnson, 1996; Nowak and Phelps, 1994). It is also necessary to blend every promotional mix element together as they have greater influence within an IMC approach as combined forces. Therefore, IMC can promote synergism internally among departments and, in turn, outside-in planning can be achieved (Reid, Luxton, and Mavondo, 2005; Stammerjohan *et al.*, 2005; Eagle and Kitchen, 2000; Phelps and Johnson, 1996).

Most managers perceive IMC as a process which encourages message integration and consistency, thus facilitating the interpretation of information for customers. Faced with an IMC approach, the customer will understand the different information and will not be confused by the vast amount of it from all contact points (McGrath, 2005b; Stewart, 1996; Duncan and Everett, 1993). However, if companies disregard IMC and different messages are not delivered in unison, it may lead to an incoherent brand image, which can negatively influence consumer buying and recall behavior (McGrath, 2005b; Stammerjohan *et al.*, 2005; Stewart, 1996; Schultz, 1993e). The combined consideration of product contact points and the consumer increases the company's awareness, and creates a positive relationship between the customer or prospect and the company (Gylling and Lindberg-Repo, 2006; Schultz

and Kitchen, 2004; Bill, 1993). Thus, different brand-customer contact points need to be carefully maintained (McGrath, 2005b).

IMC's cost-effectiveness and its apparent ability to deliver higher return on investment (ROI) has been underlined repeatedly in the literature (Holm, 2006; Reid, 2005; Duncan and Mulhern, 2004; McGoon, 1998/1999). However, researchers have failed to explain how and why these financial benefits might be achieved.

Furthermore, other traditional marketing tools, such as the product life cycle, can be considered in the different planning stages of a product, but should not *always* be taken as a blueprint, because brands are harder to damage once customer loyalty has been achieved, for example, in the case of Apple or the smoothie brand Innocent (Kotler *et al.*, 2005). However, this is not universal, as recent product withdrawals and/or brand reputation damages have indicated. For example, the link between child labor in developing countries and global manufacturers, such as GAP, Nike, or even Coca-Cola have at least shaken consumer confidence, if not to say damaged their reputations (Thomas, 2007; Johnson and Colin, 2003). A long-term brand can only be realized if it delivers an excellent pricing, distribution, and value strategy – IMC helps in better realizing these goals (Pickton and Broderick, 2005; Cornelissen, 2001; Schultz, 1997b; Miller and Rose, 1994). IMC is valuable in that it can better inform, influence, motivate, and enlighten consumers about new and existing products because of its integrative nature and its strategic long-term focus on the actual brand (Keller, 2001).

Notably, management levels within various companies have often misinterpreted IMC, that is, as a reason to cut back on the number of company employees or to decrease the marketing budget (Low and Mohr, 1999; Schultz, 1995a). Moreover, decreasing marketing budgets, growing complexity in client-organizations, and the decreasing number of employees in organizations are conditions favorable to IMC (Pickton and Broderick, 2005; Low and Mohr, 1999). But, if a company invests in establishing an IMC approach and, for example, employs a "communication czar" as suggested by Schultz

(1991), the brands' reputation can be further strengthened and loyalty among stakeholder groups further increased. The IMC budget should be introduced as a variable cost to the finance team. Seeing it as an investment will help in understanding that if more funds are allocated to the IMC budget the outcome for the company will be greater (Reid, 2003; Low, 2000; Schultz, 1995a; Duncan and Everett, 1993).

IMC benefits can be summarized as follows (McGrath, 2005a; Reid, 2003; Pickton and Hartley, 1998):

- an IMC approach aligns short- and long-term marketing in order to avoid conflicts within an organization;
- it is a sound and clear approach;
- all target audiences are considered;
- individual and one-to-one communication is encouraged;
- synergy and recall increase;
- results in financial benefits.

Although research into IMC has discovered various benefits, their basis in reality, that is, how researchers have arrived at them, should be questioned. These benefits were either derived from quantitative studies (Eagle, Kitchen, and Bulmer, 2006; Kim, Han, and Schultz, 2004; Kallmeyer and Abratt, 2001) which left little room for an actual investigation of why these benefits have occurred, or they were the direct result of researchers' credulousness when faced with marketers' positive perceptions of IMC. Most IMC research has concentrated on the opinions of advertising executives or clients. However, there has been little research directly focused on IMC benefits (Reid, 2005; Phelps and Johnson, 1996).

THE IMPACT OF PROMOTIONAL MIX ELEMENTS ON IMC

To develop customer-orientated messages, the manufacturing company should realize the importance of the information held by retailers and other intermediaries about customer wants and needs. One obstacle here is retailers' long-standing apprehension about ceding control to manufacturers, an attitude which has seen retailers guarding essential customer data

due to fears that the manufacturer may use the information to go directly to the customer – cutting retailers and other intermediaries out of the value chain (Markillie, 2006; Reid, 2003; Schultz, 1996a). To avoid such complications between different retailers, manufacturers, and distributors, Schultz (1996a) suggested the implementation of one database where input and output access is granted to all parties. An IMC approach implies that a database should not be seen as only a storage capacity for names and addresses of customers. The advantages of a customer database include (Nowak and Phelps, 1994):

- going beyond the demographics toward the psychographics of customers;
- understanding who the most loyal and profitable customers are;
- understanding consumer attitudes, buying habits, and behavior;
- gaining more loyalty from customers.

A database can help in detecting customer preferences in relation to media channels, usage, and times. A healthy brand relationship with customers can be achieved through the use of not one promotional tool but many – such as PR campaigns, TV commercials, and magazines – in order to transmit the message (McGrath, 2005b). Multiple communication tools are not important for brand relationships alone.

On the contrary, the greater utilization of marketing communication tools within an IMC approach can lead to a better overall outcome and may also deliver a more holistic picture (Smith, Gopalakrishna, and Chatterjee, 2006; Reid, 2003; Naik and Raman, 2003; Low, 2000; Phelps and Johnson, 1996; Schultz, 1996b). Consequently, advertising alone should not be made responsible for building the brand because the brand is an asset which belongs to the whole organization (Eagle, Kitchen, and Bulmer, 2006; McGrath, 2005b; Edelman, 2004; Schultz, 2004a; Drobitz, 1997/1998; Hutton, 1996; Gonring, 1994; Nowak and Phelps, 1994).

Nonetheless, it is important for the marketer within the company and advertising agency to recognize the need to involve more than one promotional tool to reach different consumer groups (Economist, 2007b; Keller, 2001;

Nowak and Phelps, 1994). Ultimately, the decision-making process is controlled by the senior management and, as such, their power and involvement are essential for the development of IMC throughout the company (Reid, 2005; Pickton and Hartley, 1998). It is vital that marketers and the senior management of a company realize that an advertising agency alone will not be able to implement an IMC program because of their limited perspective and possible lack of experience with regard to coordinating and integrating all communication disciplines. Thus, the involvement of the top management must be seen as a necessity.

Therefore, the marketers of the twenty-first century should utilize an IMC program which goes beyond the usual marketing concepts, such as the 4Ps, trying, in addition, to generate new ways of creating customer segments via a database (Johnson and Schultz, 2004; Schultz and Schultz, 2003; Hutton, 1996). The informed customer of the twenty-first century will have extensive knowledge about the product category, the product per se, or even the company in general. A firm can turn the customer's search for knowledge into a competitive advantage by engaging in an interactive dialogue with the customer, for example, through direct marketing or Internet chat forums. This may then flourish into a long-term relationship in which different promotional tools can be employed to reach individual consumer groups (Cook, 2004; Johnson and Schultz, 2004; Schultz, 1995b; Nowak and Phelps, 1994).

IMC IMPLEMENTATION AND APPLICATION

As most IMC research has been conducted with regard to advertising agencies, little is known about actual IMC application within client firms. However, it is believed that only a few organizations have reached "complete" integration (Kitchen and Li, 2005; Kitchen and Schultz, 2003; McGoon, 1998/1999). In order to draw benefits from an IMC approach, it is imperative that the whole organization, that is, across functions and subsidiaries, understands how IMC works and how IMC plans can be put into action. If this is not the case, the integration will undergo difficulties, which will in effect weaken both the corporate brand and the relationship

between product brands (Reid, Luxton, and Mavondo, 2005; Davison, Bulmer, and Eagle, 2005; Duncan, 2005; Gould, Lerman, and Grein, 1999; Novelli, 1989/1990).

The next sections explore possible IMC implementation models (Pickton and Broderick, 2005; Fill, 2002; Schultz and Kitchen, 2000a). Their advantages and disadvantages are reviewed. Also reasons for embracing the Kitchen and Schultz (2001) model in this article are explained. The final section concentrates on consumer segmentation in relation to IMC, strategic planning aspects of IMC, and the kind of research that should be carried out in order for a company to act consumer-driven.

The establishment of IMC – Fill. Fill (2002) views IMC as a change of mind-set which has to be first embraced by marketers. He also points out that certain barriers exist and hence steps have to be taken to overcome such barriers. As such, the first step in an IMC approach is to focus on the promotional activities – the marketer needs to ensure that consistency and a thematic harmonization takes place among the promotional tools employed by the company (see the first box in Figure 1).

Next, the functional coordination needs to be looked after. The different parts of the organization, such as human resources, finance, corporate communications, and so on, have to be introduced to the idea of "internal marketing relationships" in order to implement an IMC approach throughout the company (see the second box in Figure 1). Hence, an IMC approach requires a cultural shift of values and beliefs, which have to come from within the organization in order for all employees to act consumer-orientated and -driven (see the third box in Figure 1). Only then can an IMC approach be fully embraced (see fourth box in Figure 1).

This model is easy to understand and also resembles certain stages of the model. However, owing to its simplicity, it lacks significant detail and explanation. It seems difficult to overcome the problem of positioning companies at their individual stages in this particular model. Furthermore, this model did not originate from actual empirical research, but rather from the critical review of current IMC literature conducted by Fill (2002).

Figure 1 The establishment of IMC. (Source: Fill 2002: 469).

IMC rabostic model – Pickton and Broderick. In comparison to Fill’s model (2001); Pickton and Broderick’s (2005) model (see Figure 2) resulted from both a critical review of current IMC literature and empirical research (Hartley and Pickton, 1999; Pickton and Hartley, 1998).

The first step to be taken, according to Pickton and Broderick’s (2005) model, is to assess the company’s current position in the market place. Thus, feedback from previous marketing communication campaigns and outcomes of marketing communication activities need to be evaluated in order to determine the companies’ target audience(s). The next step involves the budget allocation and the review of available resources, followed by the setting of the company’s objectives and strategic plan. After determining the company’s aims, decisions at the operational level have to be made. Promotional tools need to be chosen as tactical instruments, which will assist in implementing the campaign. Lastly, the success of the new campaign needs to be monitored and evaluated

in order to understand if certain changes with regard to the marketing communication plan need to be made (Pickton and Broderick, 2005).

Although, this model is much more detailed than that of Fill (2002), it lacks significant contribution in relation to the stages of IMC implementation. As such, the overarching aim of this model is to demonstrate how a marketing communication campaign should be implemented, and not how an IMC approach can be applied throughout an organization. In addition, not much is mentioned about the sequence of the individual stages and whether they are interchangeable. Owing to the fact that this model only concentrates on the implementation of marketing communication campaigns, it does not show how IMC could be used as an approach within an organization in the long term.

The four stages of IMC – Schultz and Kitchen. Research conducted by Kitchen and Schultz (1999) focused on advertising agencies, while best practice IMC cases were explored by the American Productivity and Quality Center (APQC) (APQC 2007) led by Schultz (Webb *et al.*, 2000; Hack *et al.*, 1999; Schultz *et al.*, 1999; Schultz and Schultz, 1998; Schultz, 1998). The findings of these studies enabled a four-stage model (see Figure 3) in order to understand the development process of an IMC approach within client organizations.

As demonstrated in Figure 3, and also by Fill (2002), the first step toward becoming integrated is to coordinate IMC at the tactical level. The aim is to generate harmony among the

Figure 2 IMC RABOSTIC model. (Source: Pickton and Broderick 2005: 14).

various communication tools and the product. This is also known as the *one sight, one sound* approach. The primary focus is on the external communication of the brand. Most important, however, is that even in the first stage the IMC approach should be led by the company and not the agency. This is the “lowest amount” of integration a company should acquire, as it focuses on the tactical implementation of IMC. The difference between strategy and tactics is that the strategy shows which objectives the company wants to accomplish while tactics relate to how these objectives can be realized (Pickton and Broderick, 2005). If the communication between marketing communication functions, for example, sales, direct marketing, PR, and other departments (e.g., operation) fails, the customer might not understand the intended message from the company and may even perceive the company as a disappointment. However, at this level there is no mention of a customer-orientated approach.

The second level expands to a redefinition of communications, that is, all communication contact points that a customer or prospect can have with the company should be considered. Behavioral data should also be attained in order to understand customers, which is the first time that

a customer-centric approach is being stressed (Kitchen and Schultz, 2001).

The third step is to utilize the increasing information flow about customer behavior, attitudes, and transactional data via a database, that is, customer data is turned into customer knowledge. Accordingly, the database should provide information about the customers, for example, how often they buy from the company or when they started buying. New technologies should also be used in order to increase the information flow between employees, distributors, and suppliers. These technologies may then help in executing messages at the right time and place (Kitchen and Schultz, 2001).

Finally, the fourth stage is to deploy IMC at the strategic level. This involves marketing and finance working together for the business to become fully customer-centric as a means of generating measurable and behavioral ROI. A successful IMC approach needs to take into consideration the corporate goals instead of simply serving tactical product brand objectives (Fitzpatrick, 2005; Schultz and Schultz, 2003; Schultz, 1997a; Gonring, 1994).

Result from previous research studies with advertising agencies (Kallmeyer and Abratt, 2001; Kitchen and Schultz, 1999; Schultz, 1997d; Miller and Rose, 1994; Caywood,

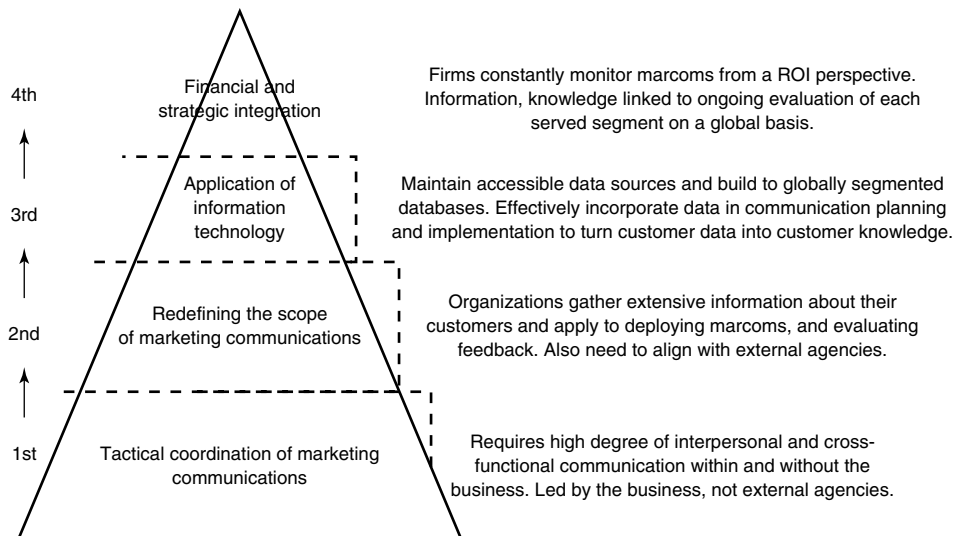

Figure 3 IMC – a four stage model. (Source: Kitchen and Schultz 2001: 108).

Schultz, and Wang, 1991b) shows that client companies may not always have the resources to implement an IMC approach at all four stages. This leads them to avoid delegating all control to a single agency, thus dividing power and responsibility among different promotional agencies. As such, during the late twentieth century, an emerging trend was reflected in the advertising agency environment with agencies forced to broaden their employees' skill sets to include a much greater variety of marketing communications skills. The aim here was to attract clients desirous of a "one-stop shopping" experience whereby agencies show a commitment to an IMC approach (Novelli, 1989/1990).

Most organizations in the early twenty-first century appear to be in stage one or two because they have yet to realize a change toward the kind of consumer-focused communication which requires close collaboration between, as a minimum, the marketing, research, and finance departments (stage four) (Kitchen *et al.*, 2004a; Schultz, 2004c). However, it should be questioned if integration among these departments is deemed to be desirable. As such, why have firms not realized this change? It may be that owing to the success of some companies, the senior management does not see it as a necessity to change current company practices.

Furthermore, it may also be possible that companies want to implement change but owing to certain reasons, for example, financial, structural or legal, the proposed change is impossible to implement. Hence, additional research is required to understand how and to what extent IMC approaches have been implemented by businesses and what kind of role agencies play as seen through the "eyes" of their clients.

In addition, financial investments for consumer research and new technologies are needed to advance through all four stages (Kitchen and Li, 2005; McGoon, 1998/1999). However, an underlying cause may also be that even though marketers and researchers have recognized the importance of IMC (Schultz, 2006b; Schultz, 2004c) and the need to focus on long-term relationship building with customers, this view has yet to be supported by the senior management. As long as IMC is perceived as a mere sales-boosting, tactical

function, a company will most likely not progress through the four stages. If its strategic significance is realized, IMC can augment the corporate and product brand's image and improve relationship management between various stakeholder groups and the company (Gylling and Lindberg-Repo, 2006; Pickton and Broderick, 2005). It also helps to create a consistent marketing communication approach focusing on the long-term brand value of both corporate and product brand, which should lead to significant synergy effects. IMC, as a strategic business process, should therefore be implemented and applied throughout the organization. This view has been expressed repeatedly by these authors (Kitchen, 2005; Kitchen and Li, 2005; Kitchen *et al.*, 2004a; Schultz and Schultz, 2003; Kitchen and Schultz, 2001; 1999; Hack *et al.*, 1999; Schultz and Schultz, 1998).

After critically evaluating this model, certain points ought to be questioned. The first stage, the same as Fill's (2002) model, primarily focuses on the coordination of promotional tools in order to create a consistent marketing communication approach. However, at this stage why should the company not include customer research data in order to create tailored messages for specific target groups? Furthermore, the next three stages principally focus on the actions of the internal departments. In Kitchen and Schultz's (2001) model technologies, customer research evaluation and the coordination between agencies and the finance department are focused on, whereas in Fill's (2002) model the functional coordination and internal cultural shift are emphasized. At this point, there is no mention of the relationship the customer has with the company, be it short-term or long-term.

What is questionable about all three models is, why have the models never been adopted by any other researchers other than those who created them? Although the Kitchen and Schultz (2001) model originated from actual empirical research, it has never been tested or verified with different organizations through a wide range of industries. Thus, it is not known if this particular model is applicable to B2B and B2C industries. However, the possibility exists that because B2B companies very often have less customer numbers than B2C companies, these firms may use a much more

consumer-driven approach where databases are utilized on a day-to-day basis (Wilson, 2006; Laiderman, 2005). Hence, the model should be “tested” within actual companies in order to see, first of all, if it is applicable, and, if so, at which stage different companies find themselves to be in.

Despite such criticisms, the Kitchen and Schultz (2001) model, in comparison to the other two models, is the only model which resulted from empirical research and focuses solely on the implementation of IMCs, and not on mere marketing communications campaigns. Although Fill’s (2002) model explains the different developmental stages, they appear similar to the one developed by Kitchen and Schultz (2001), only with less detail and explanation. Furthermore, Fill’s model (2002) does not depict the importance of measurement in an IMC approach, which is seen as a vital component of such an approach (Alvarez, Raeside, and Jones, 2006; Reid, 2005; Kitchen *et al.*, 2004a; Eagle and Kitchen, 2000).

In summary, the previous sections have paid close attention to three different models (Pickton and Broderick, 2005; Fill, 2001; Kitchen and Schultz, 2001). A significant problem is that none of these models have been tested or validated in any form. In addition, none of these models have fostered an understanding of how IMC could be applied within companies. Albeit only partially, at least, the proposed model by Kitchen and Schultz (2001) tries to give some detail on how to implement IMC within companies. The other two models are lacking in explanations and detail, and appear at this point of time, too simplistic to be adopted as models for the empirical investigation of this thesis. Part of this thesis’ empirical phase will be allocated to both reviewing the model proposed by Kitchen and Schultz (2001) and by analyzing feedback from respondents and also locating specific companies within the model.

Strategic IMC Planning

Johnson and Schulz (2004) have given some advice on how to overcome the aforementioned problems faced by organizations and agencies, and how to become a successful twenty-first century company through the application of

an IMC approach. Their findings correspond with the stages outlined by Kitchen and Schultz (2001):

- conduct market research with the aim to better understand the customers;
- understand the perspectives, motivations, and behavior of each individual customer;
- focus on the customer and not product lines;
- require responsibility from the chief customer officer/chief executive officer to maximize customer value.

The four stage model (see Figure 3) reveals that an IMC plan should derive from the contact points each company has with its customers. Typically, tracking studies are used to measure all the contacts a customer has on a daily basis, for example, different media channels with a particular firm. This should give the company a general overview of who sees what kind of advertisements in the course of a given day. The marketer should then be able to divide the “mass” into segments. These segments of consumers can then be presented with targeted messages. This can be achieved with the help of sales representatives’ knowledge as well as through the utilization of a fully functional database.

Recently, however, the climate of changing demographics and sociographics and rapidly expanding media choices have meant that traditional forms of segmentation, which have usually been based on consumer demographics, have been called into question. As a result, IMC researchers have identified the need for more sophisticated, behavior-orientated segmentation guidelines (Reid, 2005; Rogerson, 2005; Duncan and Mulhern, 2004; Yarbrough, 1996).

After grouping the customers into segments, promotional activities should be integrated such that they work according to the overall strategic IMC plan in order to accomplish the set marketing communication objectives. It must not be overlooked that communication between customers and organization should be a two-way process, that is, a dialogue or an exchange of information (Schultz, 2007; Smith, Gopalakrishna, and Chatterjee, 2006; Schultz, Tannenbaum, and Lauterborn, 1993). Each communication constituent may have specific aims but the end result should be

an integrated approach to the company's marketing communication activities (Pickton and Broderick, 2005).

After the objectives have (or have not) been realized, tests should be carried out in order to understand what has occurred in terms of the awareness, attitude, and behavior of customers. From such tests, areas for improvement can be identified. However, if the customers' behavior or attitude did not positively change toward the brand despite the implementation of an IMC approach, the organization should review its communication activities, such as its promotional tools, and examine its existing consumer groups. Thus, market research can again help in discovering and correcting errors (Duncan and Mulhern, 2004; Johnson and Schultz, 2004; Caywood, Schultz, and Wang, 1991b).

Nowak and Phelps (1994) developed a model (see Figure 4) which provides guidance for the correct employment of IMC at the strategic and tactical level. The authors have divided the aims of IMC into image and behavior orientation, whereas the center of the communication setting is represented by an accurate and up-to-date database which involves the market, message, and media strategy at the strategic and tactical level.

The model depicts changes in image perception and consumer behavior following a company's adoption of the IMC concept. Although advertising researchers have long recognized the merits and shortcomings of individual promotional tools, researchers (Nowak and Phelps, 1994) propose that when different promotional activities are used in an integrated manner, IMC can take place at the communication campaign (strategic level) and advertising (tactical) level. IMC, as shown in Figure 4, also encourages the employment of multiple messages within one campaign or advertisement in order to reach various target audiences (Schultz, 2007; Calder and Malthouse, 2005; Schultz, Tannenbaum, and Lauterborn, 1993) – this is also known in the early IMC literature as the *one voice approach* (Nowak and Phelps, 1994).

The significance of this model (Figure 4) in the IMC literature is apparent in its durability, having been adopted by researchers more than a decade after its emergence. For example, Grove, Carlson, and Dorsch (2007) have used it to

measure IMC in advertisements at the tactical level over a 20-year time period.

Figure 4 thus demonstrates how companies can become more consumer-driven and provides examples of what activities can be used to create an integrated communication mix at the tactical advertising and strategic communication campaign level. Figure 4 aims to facilitate the implementation of an IMC approach in which individual steps show the reach of IMC implementation within a company. However, as shown in the previous sections, very little is known about IMC implementation or the strategic and tactical utilization of multiple communication tools.

In addition, although the literature on global, local, or “glocal” advertising strategies is vast, consensus with regard to the ideal option of an advertising campaign has never been reached (Wells, Burnett, and Moriarty, 2003; Kitchen and Eagle, 2002; Gould, Lerman, and Grein, 1999; Sriram and Gopalakrishna, 1991; Levitt, 1983). Thus, it is not known if an IMC approach should be adopted at a global level or if respective countries can still implement and apply their own IMC approach. As such, this research addresses the above discussed issues in the empirical phase. The next section aims to provide an overview of IMC research by reviewing some of the most profound studies in the field.

BARRIERS TO IMC

Following up on past IMC studies, researchers were able to identify perceived barriers to IMC implementation and application. The following points represent a summary of the most important barriers to integration. These barriers are discussed in the subsequent paragraphs (highlighted in *italic*) (Ratnatunga and Ewing, 2005; Kitchen *et al.*, 2004a; Swain, 2004; Eagle and Kitchen, 2000; Hartley and Pickton, 1999; Pickton and Hartley, 1998; Bruhn, 1997/1998; Gonring, 1994; Duncan and Everett, 1993; Schultz, Tannenbaum, and Lauterborn, 1993):

- power, coordination, and control issues;
- client skills, centralization, and cultural issues;
- agency skills and general time/resource issues;

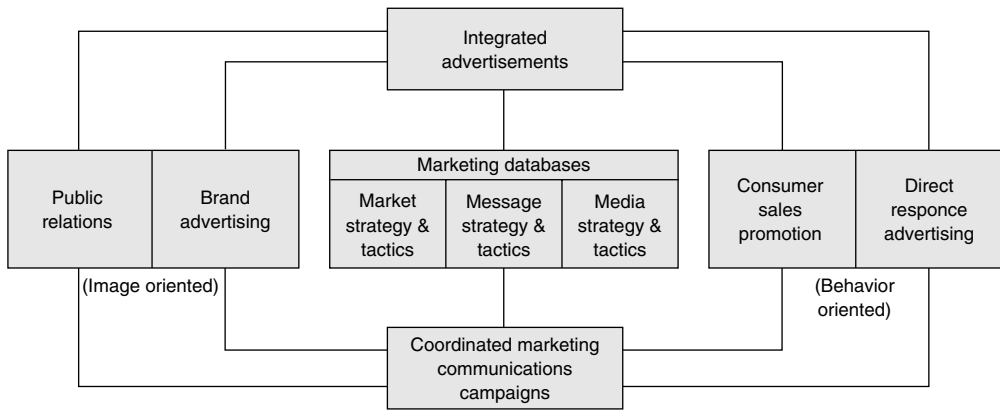

Figure 4 The integrated communications setting. (Source: Nowak and Phelps 1994: 57).

- flexibility/modification issues;
- IMC measurement difficulties;
- lack of strategic vision and business culture;
- unclear positioning at corporate level;
- subcultures within different communication departments;
- need for cross-disciplinary managerial skills;
- fear of change;
- hierarchical organization structure;
- turf battles and functional silos;
 - need to protect status;
 - need for single budgeting process and shared performance;
 - need for equal consideration across all functional areas;
 - cross-functional training;
 - inside-out communication planning;
 - short-term planning;
 - lack of database development;
- media fragmentation;
 - IMC must continually demonstrate how their mix on nontraditional media creates more impact at less cost;
- mind-set – specialization, history, tradition, experience.

IMC involves the whole company, starting with the CEO and cascading through the organization. Ideally, the corporate objectives should support the marketing objectives and vice versa. If *commitment is only given at the tactical level*, which mainly involves the marketing functions, the corporate level, such as the senior managers

or the CEO itself, will probably fail to be as dedicated to the program as they should be because they will not be directly involved with the IMC implementation and may not recognize the benefits of applying an IMC approach as a strategic process (Holm, 2006; Reid, 2005; Bruhn, 1997/1998). However, even though IMC should start at the senior level, research has indicated that this occurs only very rarely (Swain, 2004). Senior managers ought to be highly engaged in the application of IMC procedures throughout the organization, and this research further explores this idea.

IMC utilizes traditional promotional elements but it is also forced to go beyond them due to the fragmentation of media and rise of new technologies. This leads to a recognition of the import of nontraditional forms of marketing communication activities, including the interactive media (such as short message services) and the Internet (e.g., through employing consumer chat rooms) (Economist, 2007b; Gonring, 1994). In particular, marketing practitioners may interpret the concept of IMC not as prerequisite of company development but rather as a one-dimensional rationalization for another agency to make an easy profit (Stammerjohan *et al.*, 2005; Wolter, 1993). Thus, owing to increasing pressure from clients and *decreasing marketing budgets*, advertising agencies may exploit the concept of IMC to include more promotional mix elements in their functions, possibly resulting in greater profits for the agency. Therefore, practitioners need to

recognize that IMC can work in favor of the organization and not just the agency. Indeed, the agency should not be seen as the final solution to the company's problems, but rather as a mixture of consultant and communication expert, working toward the company's and the agency's aims and objectives (Beard, 1997; Bill, 1993).

Another barrier is represented by the *trend toward specialization in the twenty-first century*, for example, a client-organization could employ a direct marketing agency, an advertising agency, and packaging agency at the same time. It is noticeable that many specific agencies have been developed, such as advertising, PR, and promotion agencies, but what clients really need is integration. This requires a much broader vision where aims and purposes are refocused (Naik and Raman, 2003; Schultz, 1993b). Furthermore, such specialization may also exist within the client organization, that is, the different marketing communication functions are separated from each other. Moreover, the individual tasks within one department are again divided into small fragments, which may limit the success of an IMC program (Hartley and Pickton, 1999). Therefore, division of departments may not only present a physical barrier but may also fragment the tasks of employees such that an IMC approach is thwarted. The problem is how to successfully link the different functions and departments with each other in order to start communicating and become integrated.

It is likely that most organizations' structures do not suit IMC programs. Integration necessitates not only vertical communication but also horizontal communication, a state of affairs which often causes conflicts among the employees and their functions and tasks (Gould, Lerman, and Grein, 1999; Grein and Gould, 1996; Schultz, 1993a). Communication across strategic business units (SBUs), brands and departments, as well as from brand managers to senior managers and vice versa, needs to be secured, which requires an open-minded business culture (Kim, Han, and Schultz, 2004). IMC may lead employees to a *sacrifice of power*, which could cause disputes among them because of fears arising over loss of control and authority (Eagle and Kitchen, 2000; Gonring, 1994). However, implementation and application

outcomes of "full integration" have yet to be addressed in the IMC literature (Pickton and Hartley, 1998; Schultz, 1993b).

Thus, employees may fear that their status will be reduced or, worse still, their positions lost. The coordination and combination of various tasks, duties, and arrangements often represents the stiffest challenge to the implementation of an IMC program (Cornelissen and Harris, 2004; Schultz, 1993b). *Conflicts among employees and fragmentation of tasks* can be caused by *poor database development*, *short-term planning*, or *"inside-out" communication* – developing the communication strategy based on the product and then working toward the customer (Reid, 2005; Reid, Luxton, and Mavondo, 2005; Kitchen *et al.*, 2004b; Gonring, 1994).

The *history or background of an organization*, as well as its *traditions and experience*, can lead to difficulties when implementing an IMC program. Firstly, its structure may often be considered satisfactory, leading to a feeling that there is no real need for a change (Schultz, 1993b). However, if this situation persists and change is not being welcomed, it may result in a loss of the company's market position. Schultz (1993d) pointed out that openness to reorganization or adaptation to new organizational structures can be the key to greater integration or an obstacle to the successful implementation of IMC, depending on the company's culture.

It has been suggested (Cornelissen, 2000; Nowak and Phelps, 1994) that to overcome barriers, cross-functional tasks, such as regular meetings or introductory training, should be developed in order to leave behind authority conflicts and create team spirit among employees. Schultz (1991) came up with the post of a communication czar who is responsible for the complete implementation and application of an IMC program within the company. McArthur and Griffin (1997) also noted that it was common practice within consumer organizations to have a single person coordinating all major communication activities. But no direct reference to Schultz's (1991) concept of a communication czar was made. In addition, Schultz (1993e) also suggested that in drastic circumstances, it may be worth restructuring the whole organization with new departments

in order to reach effective outcomes and achieve appropriate changes (Schultz, 1993e).

More than a decade has passed since the first conceptual papers on IMC have emerged, but still very little is known about how IMC can help to overcome communication barriers and how IMC is implemented in firms.

CRITICISMS OF IMC

After the discussion of past research papers and barriers to IMC, it may be necessary to draw attention to the criticisms surrounding IMC. Firstly, Cornelissen and Lock (2000) argue that practitioners are only acknowledging and perceiving the concept of IMC as important owing to its rhetorical appeal and that there is little evidence of how an IMC approach can be implemented or how the concept is being used within organizations. There is also widespread acceptance that IMC advocates have tended to overemphasize on the language being used to describe IMC, rather than grounding IMC on the basis of empirical data (Cornelissen, 2003; Cornelissen and Lock, 2000; Schultz and Kitchen, 2000b). Indeed, the idea of integration and its nature should be viewed as "common sense" by any marketing practitioner, because marketing practitioners would almost certainly tend to be pro-integration rather than against it.

But Cornelissen and Lock (2000) are not alone in critiquing IMC. Other scholars have characterized IMC as too ambiguous, partially owing to its lack of a universally agreed-upon definition and the resulting divergence of operational IMC measures (McGrath, 2005a; Cornelissen and Lock, 2000; Stewart, 1996; Phelps and Johnson, 1996; Nowak and Phelps, 1994). To overcome this validity problem, Schultz (2004b) proposed a new and revised version of IMC, adopted by the American Marketing Association (2007). In addition, it seems that most researchers have recognized the strategic importance of IMC even if evidence in relation to the realization of the strategic employment of IMC within companies is scarce.

Furthermore, Cornelissen and Lock (2000) reproached IMC as nothing more than a managerial fad. Indeed, current IMC studies, as for example Schultz and Kitchen (2000b), have noted that IMC is still in its pre-paradigm

stage and cannot, therefore, be called a theory. Despite this, in the past two decades many marketing communication investigations on IMC have proven that IMC is widely accepted among marketing and PR practitioners (Kitchen and Eagle, 2002; Reid *et al.*, 2001; Kitchen and Schultz, 1999; Kitchen and Schultz, 1998; Schultz and Kitchen, 1997; Miller and Rose, 1994; Duncan and Everett, 1993).

In addition, PR-oriented literature in the early 1990s argued against integration of marketing and PR. In an article by Miller and Rose (1994), the two authors reported on the debate at the conference for Education in Journalism and Mass Communication in 1993. Other papers and reports were also reviewed, such as that by Ehling, White, and Frunig (1992) who claimed that "the public relations function of excellent organizations exists separately from the marketing function . . ." (Miller and Rose, 1994: 13). These researchers view PR as a subject on its own, serving various stakeholder groups in a different manner than marketing does. Thus, in the eyes of these practitioners and researchers, PR should not be seen as a mere function of marketing. However, IMC was and still is perceived as reality and an important subject area to both marketing and PR practitioners, albeit for sometimes different reasons (Miller and Rose, 1994; Nakra, 1991; Niederquell, 1991).

To date, more than 100 articles and papers have been published about IMC, and although it is an emerging discipline, the fundamentals of IMC are becoming established (Patti, 2005). Schultz and Kitchen (2000b) note that the validity of a concept or theory does not only consist solely in a universally accepted definition. Although one cannot come up with a definite figure for the number of investigations needed before a specific concept can be called a theory, different concepts and frameworks are needed and ought to be interrelated and linked before an actual theory emerges (Carroll and Swatman, 2000; Walsham, 1995). As such, it is not yet known if IMC will ever emerge as a theory or if it is a concept which needs to be linked to other communication concepts to produce a different theory.

Hypothesis testing in relation to the tactical integration of marketing communication tools has begun to emerge (McGrath, 2005b;

Stammerjohan *et al.*, 2005; Jin, 2003/2004). On the other hand, different theoretical constructs and concepts are still needed to lift IMC to the theoretical level. With the apparent research focus on advertising agencies, too little research has been carried out on client organizations for there to be a demonstrable link between theoretical constructs and the experience of actual firms. As such, IMC theory building as seen from the point of view of a strategic business process has only recently begun to emerge.

In the past, researchers have argued (Cornelissen and Lock, 2000; Pickton and Hartley, 1998; Hutton, 1996; van Riel, 1995) that the historical framework and the origins of IMC can be traced back to the 1970s and 1980s, with the term *IMC* simply becoming more popular during the last decade. Caywood and Ewing (1991) also acknowledged that some ambitious practitioners of the 1950s tried to implement integrated programs and failed only because of their lack of knowledge and technology. However, it is undeniable that the nature of communication has changed dramatically during the last 20 years. Today, marketing communication practitioners must utilize these new kinds of communication, for example, the Internet, networks, value chains, direct marketing campaigns, and databases, all of which have had a significant impact on companies.

In fact, the concept of IMC has grown out of such changes (Economist, 2007b; Grove, Carlson, and Dorsch, 2007; Schultz and Kitchen, 2000b). Although practitioners may have attempted to coordinate and integrate marketing communication mix elements at the tactical level even before the earliest IMC papers were published, IMC as a strategic business process focusing on long-term brand value and customer relationship management is a product of the late twentieth century. With the aforementioned changes occurring in an increasingly global context of commercial competition, the adoption of an IMC approach throughout the company appears to be valuable, if not necessary, to sustained success.

IMC is often seen as a technique that belongs to marketing practitioners rather than to the organization, whereas PR practitioners may view it as a limiting approach given that marketing does not incorporate all functions of

PR (Wightman, 1999; Miller and Rose, 1994; Wolter, 1993). Most advertising or marketing practitioners are in favor of IMC, whereas public relations practitioners are often against it. This may be due to the fact that IMC tends to be seen by PR practitioners as an attempt to bring PR under the umbrella of marketing (Miller and Rose, 1994). Wightman (1999) also suggests that many advertising agencies use IMC to incorporate PR due to decreasing client budgets. The central argument put forward by Miller and Rose (1994) is that marketing is often viewed primarily as a function which serves the customer as a stakeholder, while PR directs messages to different stakeholders.

Furthermore, Cornelissen and Harris (2004), in exploring the working relationship between marketing and PR, discovered that the majority of firms have not integrated these functions and that they rarely work in unison. Ideally, these two communication functions should be combined. Thus, the difficulties that practitioners face in assimilating these two functions may be seen as a barrier and also as a flaw insofar as PR practitioners may oppose IMC in order to prevent themselves from being subsumed by the "marketing" banner, thus denying themselves access to IMC's strategic value. Then again, neither marketing nor PR practitioners should make final conclusions because despite a vast amount of theorizing, little detailed empirical work on IMC within organizations exists to support the conceptual perspectives already advanced.

SUMMARY AND CONCLUSION

There is little doubt that IMC is increasingly important in the twenty-first century. Technology makes integration possible and IMC programs have already been adopted by various organizations, such as FedEx and Dell. One of IMC's aims is to create synergy among the different marketing elements in order to achieve short- and long-term returns (Madhavaram, Badrinarayana, and McDonald, 2005; Naik and Raman, 2003; Stewart, 1996). Other benefits of an IMC approach are greater consistency among the various communication messages and functions, cost savings, easier working relations between different department,s and a

better utilization of media and promotional mix elements (Pickton and Broderick, 2005).

This article has focused on the concept of IMC, past research studies on IMC, barriers to its implementation, and critiques of the concept. The investigation into past research studies has proven that although practitioners have indicated that IMC is demanded from firms, little research has been carried out in relation to client firms themselves, especially in the non-English-speaking world. Thus, the progress of IMC is not yet over. In fact, it has just begun.

subliminal advertising

Anthony Grimes

The term *subliminal advertising* refers to marketing communication that is presented below the threshold of conscious perception. It is often related to words, symbols, and pictures that are embedded in another medium (e.g., a picture, TV program, or advertisement), and is hypothesized to exert a subconscious influence on consumer attitudes and behavior.

Although widely accepted in the domain of psychology for some time previously, the “commercialization” of subliminal perception (Broyles, 2006) occurred with the publication of a study by James M Vicary in *The Hidden Persuaders* (Packard, 1957). Vicary claimed to have increased the sales of popcorn and cola in a New Jersey cinema by projecting onto the screen subliminal instructions to consume these products. Despite the fact that he subsequently admitted the “experiment” was a hoax and that the results were invented, the notion of subliminal advertising continues to prick the public consciousness and remains a source of fascination and fear (see Nelson, 2008).

Empirical evidence for subliminal advertising effects, however, is equivocal at best (see Trappey, 1996). In support of this phenomenon, subliminal embeds have been shown to enhance hunger (e.g., the word “beef”), thirst (e.g., the word “Coke”), and sexual arousal (for a review, see Broyles, 2006). More recently, enhanced physiological states (e.g., thirst) have been found to provide the necessary conditions for the subliminal manipulation of product consumption and evaluation (Strahan, Spencer, and Zanna, 2002; Berridge and Winkielman, 2003). Such findings support the claim that subliminal advertising may have some merit in producing specific effects in the early phases of the consumer decision-making process (Cuperfain and Clarke, 1985; Theus, 1994; Dijksterhuis *et al.*, 2005).

The somewhat limited supporting evidence, however, should be considered alongside continuous and consistent failures to demonstrate subliminal advertising effects (e.g., Champion and Turner, 1959; Kelly, 1979; Gable *et al.*, 1987; Rosen and Singh, 1992). Furthermore,

both experimental and applied replication of these effects has proven to be almost impossible (see Broyles, 2006). However, skepticism surrounding the use of subliminal advertising is primarily fueled, not by doubts over the *existence* of its influence, but by the notion that this is simply a weak analog of that created via supraliminal perception (Theus, 1994; Trappey, 1996). The effects are so small, it is argued, that they are easily subsumed by others in the consumption environment (see Broyles, 2006). Such claims lend contemporary support to the conclusion of Moore (1982) that subliminal advertising is, “an epiphenomenon, not worthy of any marketing application.”

In light of such criticism, and despite continuing popular misconception, the influence of subliminal advertising has been largely discounted by academics, advertisers, and regulators alike (see Broyles, 2006; Nelson, 2008). This is not to say, however, that the potential for such influence has been entirely rejected, particularly in relation to the early (attitudinal) phases of consumer decision making and certain persuasive contexts. For example, Theus (1994) suggests that subliminal priming of positive self-image could enhance the effectiveness of public service advertising to reduce tobacco, alcohol, or drug abuse.

Although it remains difficult to make the case for a direct link between subliminal perception and consumer behavior, however, a much stronger argument has been made for other forms of nonconscious advertising effects: phenomena that do not relate to subliminal perception, but a lack of conscious awareness of the *processing* that occurs between exposure and outcome (see Chartrand, 2005; Dijksterhuis *et al.*, 2005). Indeed, it should be stressed that, while the fleeting reference to Vicary’s hoax stole the headlines, the concept of *subliminal advertising* is little more than a footnote in *The Hidden Persuaders* (Packard, 1957). Rather, the focus of Packard’s text is the effect of nonconscious processing that occurs following *supraliminal* exposure to advertising stimuli. In this respect, he argued that advertising could influence perceptions, attitudes, emotions, and impulses without consumers’ conscious awareness of the extent or nature of this influence. Such effects have since been the subject of a rich vein of

motivation research in both psychology and marketing over the last 40 years, during which time they have been demonstrated to be robust, replicable, and of potentially great significance to marketers, advertisers, and consumers.

**sustainable marketing: collaborating with
and cloning consumer 3.0**

Heather Honea

In the twenty-first century, business will be responding both directly and indirectly to the issues and opportunities of a globalized market and work place, resource scarcity, climate change, and the digital networked world (Gitsham, 2008; Friedman, 2008). At the same time marketers will be tasked with creating, communicating, delivering value to and building relationships with multiple audiences (consumers, employees, associates). A key ally in navigating this complex business environment and pursuing integrated marketing communication will be the audience themselves. Marketers and consumers will become collaborators as a matter of necessity.

**COLLABORATIVE MARKETING: RELY ON THE
CROWD OF CONSUMERS**

The degree to which the digital networked environment connects and aggregates individuals has forced the “crowd” into the marketing equation. Search, choice, and consumption experiences have always been impacted by the social groups and networks in which consumers participate. However, the tools by which this influence is exerted are redefining all three. Group filtering and recommendation systems allow firms to deliver highly relevant and even personalized product offerings to their customers. Collaborative filtering techniques identify similarities in ratings patterns by users or in purchase behavior and are used to recommend consumption options. Amazon knows that if a particular consumer bought product A and B, when another consumer examines or purchases product A, that consumer should be informed that he might also like product B. Netflix’s Cinematch system allows users to rate movies and aggregates these ratings to create recommendations for other like-minded users. Social bookmarking tools such as Delicious rank content based on user recommendations, so the crowd decides what news and information should be highlighted.

Relying on the audience to rank outcomes does not diminish the quality of recommendations or decisions. If there are diverse, independent, specialized, and local opinions in the crowd as well as a mechanism to convert private judgments into a decision, a crowd may actually be able to outperform other selection methods (Surowiecki, 2004). In fact, aggregation of information from the audience can actually achieve greater accuracy and relevance than by expert individuals. One such type of aggregation is a prediction market. A prediction market is an exchange in which participants vote on a possible outcome (e.g., product) by buying and selling shares similar to the stock market. The price of shares for a particular product is driven by the wisdom of the crowd, with a higher share price for those products the crowd believes have the greatest chance of success. Work by Ho and Chen (2007) contrasts expert opinions and consumer surveys regarding purchase intentions with prediction markets in order to identify potential mechanisms to select the most promising new product ideas and improve supply planning. They present examples from the movie, IT, and health care industry and show that prediction markets are highly accurate in these domains (Ho and Chen, 2007). Thus, the choices and decisions of the crowd may be relied on to provide critical market insight.

The value of the crowd, however, may be most striking relative to production. Firms face limits on what they can afford to produce due to the cost of pursuing certain activities in an organized way. Collaborative tools lower the costs of coordinating groups and extend the scope of production activities (Shirky, 2008). Wikipedia is an encyclopedia that does not rely on the expert-driven method of content generation but instead relies on production from the crowd. A 2005 study published in *Nature* ranked Wikipedia as comparable to *Encyclopedia Britannica* in terms of error (2.92 mistakes per article for Britannica and 3.86 for Wikipedia) but with far more content (Giles, 2005). Apart from cost considerations, markets and audiences must be of sufficient size to justify the allocation of firm resources to production. In the past, niche or local information was not available beyond the small community who participated in or experienced an event. Photosharing sites

2 sustainable marketing: collaborating with and cloning consumer 3.0

such as Flickr and blogs allow for multiple perspectives and widespread coverage of all news and niche events. With the democratization of production, where everyone has the tools to produce and create, niche products and content are made available by the crowd – dramatically increasing the population and type of goods available (Anderson, 2006).

Giving over control to the audience does come with risk; and the challenges of relying on consumers for strategy or tactics are well documented. Chevrolet's "Create your own Chevy Tahoe commercial" is one example. This campaign made available online graphic and audio assets as well as text insertion capabilities so that users could create their own Chevy Tahoe advertisements. As opposed to engaging Tahoe enthusiasts as the company expected, the most widely circulated commercials criticized the SUV for its gas mileage and its negative impact on the planet (Bosman, 2006). When the crowd, or more aptly the mob, takes over content generation or messaging, the outcome is rarely as planned.

PARTICIPATORY MARKETING: THE INTEGRATED CONSUMER

The crowd is made of up an "authoritative new consumer who creates, shares, and influences" (Mooney and Rollins, 2008) and these consumers are insinuating themselves into every aspect of the marketing process. Individuals that contribute as well as consume are referred to as *prosumers* (Kelly, 2005). The *prosumer* is differentiated from the traditional consumer in that he/she is active (as opposed to passive) in terms of the business, marketing, and production activities. The prosumer may be an amateur providing professional quality services such as photography (professional consumer), the writer on Wikipedia that produces content but also consumes it (producer consumer), or the independent specialist not associated with a particular institution that provides expert support (provider consumer) (Prosumer, 2009, Retrieved September 10, 2009).

Prosumers are not just partners in the cocreation of goods and services. They have taken control of the supply side of markets. User-generated content fuels the material for

video sites, participants' commentary determines the vibrancy of a blog, and the users of social and professional networking sites such as Facebook and LinkedIn determine the attractiveness of the site. In metaverses such as Second Life, participants act as architects that "build" structures, designers that sell high fashion, and artist that create works for galleries. These participants enhance the experience for other users and in some cases are compensated by those users for the goods and services they provide.

In the brick-and-mortar world, consumers managed minimal distribution activity, selling their goods at flea markets and annual garage sales. Occasionally, they placed an advertisement in the Penny Saver or classifieds but usually ended up making a trip to Goodwill. Now, entire consumer-to-consumer (C2C) markets exist, such as eBay and Craigslist. Previously, consumers relied on expert sales agents who had access to proprietary systems to facilitate their purchases. A real estate agent provided them housing listings, a travel agent detailed potential itineraries and booked their travel, a salesman duped them into a car purchase, and a doctor explained their medical condition. Today, prosumers vet houses on Realtor.com, read hotel reviews and purchase airline tickets online, research car manufacturer pricing to dealerships on Edmunds.com, and self-diagnose at WebMD.

Prosumers are able to negotiate purchase price from a position of strength. With a touch of a button they can compare product price across 10 different stores or bid at their preferred price for a product at auction. They leverage collective buying power to gain volume discounts. At Groupon.com users can take advantage of a group coupon and so long as a certain number of buyers agree to participate, they enjoy the benefits of a discounted price. Moreover, many consumers have effectively transferred transportation costs to the seller. They conveniently skip the trip to the local retailer who traditionally warehoused products and instead have items delivered directly to their door (free shipping included).

THE CONSUMER 3.0: NARCISSISTIC ACTIVIST

At the same time consumers take control of the marketing mix, the availability of free goods and

services (both legal and illegal) is changing their price expectations. Consumers have access to free email accounts, free entertainment content on YouTube, and free news from almost every newspaper and magazine except the Wall Street Journal. So while a recent study by the Pew Research Center shows that newspaper and news magazine readership is up, these media outlets are in crisis because more people in the United States get their news online for free than pay for it (Isaacson, 2009). Free is the new expected price point for consumers (Anderson, 2008).

Technology advances have fueled notable shifts in psychographic and behavioral characteristics of consumers as well. The mental environmental movement, a phrase coined by Kalle Lasn of Adbusters, refers to actions consumers take to eliminate mental pollution resulting from the overwhelming supply of media and marketing messages they are bombarded with daily. As the technology becomes available to filter and skip marketing communications, consumers rely on pop-up blockers, spam filters, and personal video-recorders to fast-forward through advertisements. In the best of scenarios for marketers, consumers program their own entertainment experience at Hulu (a website that offers commercial-supported streaming video of TV shows and movies from the major networks), selecting when and what they are going to watch and determining the slotting of the commercials they view.

At the same time that they adopt better tools for filtering marketing communication, consumers are perpetually connected to the digital world, multitasking during every free moment, and making themselves available for communication across larger social networks. Most striking in this dynamic is not the attention deficit or extension of social connections, but the exaggerated focus on self. The opportunity to turn the camera lens inward and provide a personal broadcast to the world is cultivating new levels of narcissism. Jean Twenge and her colleagues have documented increasing levels of narcissism in college and high school students compared to previous generations. Narcissistic traits including an inflated sense of self linked to overconfidence, materialism, lack of empathy for others, and relationship problems, are

increasing in college students (Twenge *et al.*, 2008; Twenge, 2008).

Opportunities for narcissistic exposure abound. Whether it is parents sharing updates and photos of their children on a daily blog or individuals putting their photos up on Hot or Not to have the world provide ratings on their attractiveness, citizens are sharing more and more about their personal lives than ever. The opportunity to stare at one's reflection on Facebook and then share it with everyone is tempting every age group. The fastest growing segment in social networking is women over 55 (Fastest Growing Demographic on Facebook: Women Over 55, Retrieved October 08, 2009).

Interestingly, rising levels of narcissism in the United States are matched with increasing levels of consciousness toward the environment and sustainability. The number of consumers focused on health and fitness, the environment, personal development, sustainable living, and social justice is increasing annually (French and Rogers, 2006). Consumption choices and brand affiliations reflect these consumer values. Consumers carry reusable bags to the store, seek out organic foods and natural products, and purchase carbon offsets for their travel.

As consumers focus on more sustainable consumption, they have heightened expectations that firms engage in socially responsible behavior (Yoon, Gürhan-Canli, and Bozok, 2006). It appears that newly empowered consumers will take time away from gazing at their photos on Facebook to take punitive action toward firms that fail in this domain, acting as de facto regulators of corporate and social responsibility. The type of action consumers will take (civic mode) varies as a function and form of corporate social responsibility failure – the action they take may be to send a message out on Facebook but they take action nonetheless (Russell and Honea, 2009).

CLONE THE CONSUMER: DEVELOPING ARTIFICIAL-CONSUMER-INTELLIGENCE (A-C-I)

Marketers are not entirely powerless in the partnership they develop with prosumers. As people post their opinions, ratings, and personal information across the Internet, there is more

4 sustainable marketing: collaborating with and cloning consumer 3.0

data than ever available about these individuals. Hourly these individuals are chronicling their activities, interests, and actions – infinitely expanding the universe of content about themselves. In the *New York Times Sunday Magazine*, Clive Thompson identified services that allow people to report on the sites they are surfing (Tumblr), the places they are traveling (Dopplr), where they are located (Loopt), or what they are doing (Twitter). The data feeds from these services allow for an incredible level of ambient awareness of the person broadcasting, by anyone interested in the information. Thompson suggests that “Each little update – each individual bit of social information – is insignificant on its own, even supremely mundane. But taken together, over time, the little snippets coalesce into a surprisingly sophisticated portrait . . . like thousands of dots making a pointillist painting. This was never before possible, because in the real world, no friend would bother to call you up and detail the sandwiches she was eating.” (Thompson, 2008). Firms can gain access to a simple aggregation of this type of information from users’ feeds or when an individual joins a brand’s page on social networking sites. Developing such digital intimacy is impractical for many firms but certainly possible. If marketers can find a way to manage the data, they can develop a profile of a consumer that is so detailed they will know the exact time of day consumers take their breaks and what they consume for an afternoon snack.

Even if firms choose not to construct these detailed profiles, prosumers will construct virtual representations of themselves in the form of avatars. According to the Gartner Inc. IT researchers, by the end of 2011, 80% of active Internet users (and Fortune 500 enterprises) will have a “second life” in a virtual world. In massively multiplayer online role-playing games (MMPORG) such as World-of-War-Craft and metaverses such as SecondLife, individuals have great flexibility in the avatars they create. Avatars may be extensions of the self and can be imbued with idealized, actual, or experimental characteristics. A person’s avatar may be created with more attractive features, features intended to closely mimic physical features, or might be a different gender than the person behind the avatar. Additionally, individuals may develop

avatars that have only moderate connections to the self. A *projected other* refers to an avatar imbued with idealized characteristics of another, for example, a woman designing the perfect “boyfriend.” Finally, an individual might select a pure fantasy representation such as a dragon as their graphic representation. Individuals will take actions and make choices from the perspectives of the different personas engendered by their different avatars. While marketers are well versed in appealing to the idealized or the actual self, making connections with experimental, fantasy, or projected others may be quite complex. The multiplicity of representations will offer rich data regarding consumers’ preferences and curiosities, but will be akin to profiling and marketing to a schizophrenic.

Citizens do not limit their data sharing to virtual worlds and social media sites. Increasingly people have begun to share data with firms so that they can “outsource” knowledge and responsibilities to the firm. They set up automatic bill pay, and do not bother to memorize phone numbers because they are perpetually connected to such information through their mobile devices. They allow word processing programs to “finalize” the spelling of a word as they write a report or reevaluate the tone of an email if the program provides them an “abrasive alert.” At their favorite online stores, customers create wish or registry lists, offering up a databased list of the top products of interest to them. Every time they update their registry, consumers are providing marketing research to firms.

As individuals share more and the network is able to track more, the consumer data grows exponentially. In concert, there is a proliferation of tools that provide consumers’ data about themselves. These tools expose consumers to new products, allow consumers to explore their preferences, and help them evaluate their own behavior. A visitor to Pandora enters the name of his favorite artist and instantaneously is provided a playlist or personal music channel. The tailored list comes from an extensive analysis of the musical qualities of the song that was entered and is matched to other songs with similar

attributes. A consumer simply shares a preference and is immediately provided a set of products for sampling.

Online data tools can also be used to optimize or modify consumption and behaviors. Online calculators allow for the assessment of diet goals and carbon footprints. These calculators are integrated with purchase options. Consumers can calculate the carbon impact of a trip they are going to take and purchase offsets immediately after buying an airline ticket. Personal dashboards offer the opportunity to track, quantify, and review personal consumption patterns. For instance, Google PowerMeter receives information from utility smart meters and energy management devices and provides customers with access to their home electricity consumption right on their personal iGoogle homepage. Additionally, smart home performance systems allow users to manage media, lighting, energy, and water consumption remotely.

The ideal material for research, communication, and promotion is offered up freely to marketers by consumers on a daily basis through such data collection tools. Marketers must simply help consumers organize this information in a meaningful or useful manner for both parties. To this end, customer-intelligence technology has begun to incorporate distributed computing and machine learning. Causata is working to develop a "multichannel customer interaction platform [that will] constantly update its profiles of customers, effectively learning from any purchase or query and adding that to personal information in its database. It might know that you like skiing, wine and jazz, and be cognizant of your location and calendar. Imagine a text message that includes your spouse's name in a reminder about your upcoming anniversary because you inserted the date on a wedding registry years before" (Harris, 2009). It might also include a recommendation for a romantic restaurant that carries your favorite wine and plays jazz music.

While this type of customer intelligence is characterized as predictive analysis, unique potential exists in the collection of data from consumer profiles, personal feeds, public posts, dashboards, and calculators. Kelly (1998) argues that collection of these pieces of information, in aggregate, has the potential to represent artificial

intelligence. If marketers offer appropriate tools and facilitate the collection of certain types of data, the customer profiles they build will be akin to clones of those consumers. The consumer intelligence available from such clones may offer insights into behavior and choice that consumers could not share, even if they were motivated to do so.

SUSTAINABLE MARKETING: MARKETERS AS AGENTS OF THE PROSUMER AS OPPOSED TO AGENTS OF THE FIRM

The days of the passive couch potato are long gone. Consumers are resistant to being pitched, expect to control every step of the marketing interaction, impact the brand, and work to ensure they receive maximum value for every exchange (Hurst, 2003; Jaglois, 2003). To address this new breed of consumer, marketers must shift from acting as an agent of the firm to serving as an agent of the consumer. Such a shift demands a change in the marketing paradigm, morphing relationship marketing and fully integrating the prosumer into the marketing process. Kotler has recommended a shift to *holistic* marketing that focuses on long-term mutually satisfying relationships and coprosperity for all stakeholders (Kotler, Jain, and Maesincee, 2002). Others have labeled the model *organic* marketing because it "markets from the audience rather than to it" (Hurst, 2003), *collaborative* marketing because it entails working together with customers to create value, and *participatory* marketing because it is marketing with customers rather than at customers.

In this article, all these concepts are encapsulated under the umbrella of *sustainable marketing* (Fuller, 1999), which is described as marketing that focuses on developing long-term mutually satisfying relationships and coprosperity for all stakeholders by collaborating with the audience on the marketing process. Envisioning integrated marketing communication and brand building as the creation of a marketing ecosystem, where artificial consumer intelligence is used to sustain the organization and at the same time support the prosumer to better their consumption decisions, will require a broader perspective of the prosumer's processing of and reactions to the consumption environment.

Narrative (versus analytical) processing involves the “integrative melding of attention, feelings, and imagery” that immerses an individual into a narrative or storyline (Green, 2004) and facilitates the mental simulation of events outlined in marketing communications (Escalas, 2007). Narrative transportation enhances persuasiveness of storyline because it heightens affective intensity and realism of the experience and mitigates counter arguing (Green and Brock, 2000). An emerging body of research suggests that people’s transportation into the storyline of an advertisement serves to blur the divide between the real and hypothetical and in turn facilitates persuasion Escalas (2004, 2007). Recent work by the author along with her colleagues shows that if you connect people to the marketing narrative, while transported, they go beyond the content of the narrative and build on the storyline by personalizing their own story. People not only make the leap to picture themselves in the scene but play an active role in the construction of the scene to suit their specific tastes (McFerran *et al.*, 2009). Integrated marketing communication must allow the consumer to cocreate marketing narratives. To do this, marketers will have to work in partnership with prosumers to construct a valuable and relevant narrative, inviting all facets of the consumer’s different personas to participate in the development of that narrative.

Beyond co-creating narratives, marketing must develop deep insights into consumers. As marketers attempt to clone the consumer, it is important to recognize that pursuing artificial intelligence through tracking of data and machine computation requires some understanding and incorporation of “the related physical, perceptual, social, and emotional facets of intelligence” (Jenkins, 2003). Rational logic-based processes are not the sole determinants of action and decisions, but irrational and nonrational processes are major influences as well. Such reactions involve consumer responses that are spontaneous or emotional in nature. Not only do such reactions play a critical role in rational decision-making (Picard, 2003), many consumer decisions that on the surface seem to be driven by reason are better explained by emotional responses. For example, when consumers act on promotions, how they

feel about a deal may be as important as the economic benefit they receive (Honea and Dahl, 2005). In fact, when the consumption context triggers certain social emotions such as guilt and pride, these emotions may actually compete with more reason-based or economic decision factors Dahl, Honea, and Manchanda (2003, 2005). When consumers experience some contradiction in their consumption reactions, they may actually engage in a sort of double-think in their decision-making. Depending on whether individuals rely on their elaborative or spontaneous response, a consumer may have entirely different evaluations of the same product or experience (Honea, Morales, and Fitzsimons, 2006). Cloning the consumer demands attention to these dualities in consumer reactions and decisions.

Such dualities may be particularly relevant as marketers try to pair sustainable marketing with sustainable consumption. Sustainable marketing is only sustainable when complemented by sustainable consumption. Sustainable consumption is consumption that is more efficient but may also involve consuming less or differently (Cohen, 2007). As such, sustainable marketing will need to help consumers organize, optimize, modify, and improve consumption behaviors. The idea of a utility company helping consumers figure out how to use less energy, instead of more energy, is a bit of paradox. Yet, it is a new marketing reality. Assisting consumers in the level, timing, and composition of demand in a way that will help *the individual* improve consumption behaviors as opposed to simply delivering on objectives of the firm will likely be the most sustainable marketing action. Thus, a key aspect of integrated marketing communication will be the reeducation of the consumers about themselves, addressing dualities in prosumers’ reactions to consumption options, and facilitating the prosumer to make the best decisions even if this requires restructuring firm goals.

historical overview of advertising promise

Zlatko Jančič

INTRODUCTION

It is frequently argued that modern advertising is no longer working. Advertising, which has helped to shape human history and especially that of the last 500 years, is now on the decline. The reasons are many, from the plethora of new media offerings to the drastic changes in the demands of consumers. This article seeks to shed some light on whether the forecasts that advertising is in decline has merit, through a historical analysis of disruptive periods in the development of the advertising profession. It is demonstrated that the current catastrophic predictions are not now being put forth for the first time but that there have been quite a few periods in the past with similar predictions. However, advertising has always found the means to remain standing. It has proven to be extremely tenacious and creative and has always been able to adapt. It appears that advertising will emerge from the current crisis, though, of course, in a new set of robes.

In this contribution, the focus is on only one aspect of the development of advertising throughout history. It concerns the different strategies or approaches the advertiser has used to argue with the offer and create a promise. In doing so, the author follows his definition of advertising, which reads as follows:

Advertising is planned, ordered and signed creative (mass) communication, which aims to promote the exchange process between providers and consumers, giving exercisable promises.

The starting point of this analysis is any entity that triggers advertising discourse in order to stimulate interest on the side of consumers. Each period that is studied is termed an *era of advertising*, as it represents the prevailing assumptions about the best way to resolve the communication problems of the time.

THE DEVELOPMENT OF APPROACHES TO ADVERTISING PROMISE

Various authors try to classify the history of advertising. Some separate the core historical periods (Arens, 1996), while others indicate only the important dates in the historical development of advertising (Egan, 2007).

Reviews of the history of advertising in one part sometimes only deal with the predominant modes of operation at that time, for example, to that part of history that covers the use of print and/or electronic mass media. One example is that of Preston (1971), who mainly deals with the historical development of media and corresponding advertising tactics. Another example of a source regarding the advertising history in the United States is *The Mirror Makers* by Fox (1997). Unfortunately, this author focuses exclusively on the development of US advertising agencies, and only on the narrow part of the history from the nineteenth century to the 1970s. Some new insights into the contemporary development of advertising using global perspective have recently been presented by Boutlis (2000), Leiss *et al.* (2005), and especially Turgate (2007).

The premise is that the existing classifications are not sufficient. These works do not reveal all of the past as well as the modern turning points relevant to understanding the development of advertising, and much less provide clues for the prediction of its possible future. This article will therefore seek to offer a more detailed periodization. Ten approaches to planning advertising copy strategy are proposed, which are named as the *eras of advertising promise*. They represent a relative sustainability through time and surpass the level of mere fads. In doing so, it is not presumed that all the details of the long and rich history of advertising have been covered. It is hoped, however, no visible era with crucial explanatory significance for advertising history has been overlooked.

The ancient era. Although it may be an attractive idea for some researchers, advertising is not, however, a typical product of capitalism. It would be closer to the truth to say that it is the product of a civilized, cultural society. The Latin root of the word *civis* means citizen,

2 historical overview of advertising promise

a contributor to the culture (Lat. cultura) and a spiritual, intellectual, social, and artistic life (Osborne, 2007, p. 4).

Some ancient cities had at their peak several hundred thousand inhabitants. In such agglomerations, people could not always follow the principle of self-production and were therefore forced to meet their needs by entering into numerous processes of exchange or trade. The necessary condition for the success of such cities was a surplus of agricultural products, trade development, and manufacturing and service activities. A boosting engine for large cities such as Rome was also wealthy legionaries, who required a range of services in return for their money gained in combat (Osborne, 2007). These people started buying products made by unknown others (Leiss *et al.*, 2005). Urbanization, the division of labor, and the emergence of money as a medium of exchange led to the crossover from the traditional society based on social ties and barter trading to the trade based on economic exchange. Advertising was certainly one of the essential tools in this process of exchange. Advertisements in the form of wall inscriptions, signs of craftsmen, obelisks, papyrus, ceramics, and so on, have been discovered in ancient cities such as Ur and Babylon, and later, of course, in Rome, Athens, Pompeii, and Carthage. In the ruins of an Italian city, Herculaneum, archeologists found a wall with color announcements of gladiator struggles. The wall was arranged in a way similar to today's deployment of poster areas (Preston, 1971). In ancient cities, the advertisers also implemented so-called public criers (Presbey, 1929), who were sometimes accompanied by musicians. This suggests that the scale and development of advertising may have been earlier and of greater magnitude than assumed. It is also possible to conclude that ancient advertisers understood the principles of creative copywriting well, as is evidenced by the following verse of a trader from Athens:

For eyes that are shining, for cheeks like the dawn,
for beauty that lasts after girlhood has gone,
for prices in reason, the woman who knows,
will buy her cosmetics at Aesclyptöe (from Egan, 2007, p. 2).

These examples support the thesis of two advertising histories, ancient and modern, advocated by Presbey (1929), which promotes the notion of advertising development far into the precapitalist societies.

Although there are some clear advertising artifacts of ancient times, on the basis of these, it is difficult to assess the full nature of their advertising promises. We can assume that, more likely than broadcasting, narrowcasting with a mixture of informative and persuasive communication was used with a strong presence of dialogue in the processes of exchange.

With the collapse of the Roman Empire and the influx of barbaric tribes, Europe entered the Dark Ages. In the year 400, Rome had half a million inhabitants; in the year 600, only 50 000 (Osborne, 2007, p. 163). The collapse of big cities also meant the collapse of civilization and culture. During this period, there was a drastic decline in education and literacy in Europe and with this a huge decline in the presence of advertising. History, however, reports of criers, drummers, messengers, and so on, who traveled across the country disseminating news, and often advertisements, but their impact on history remains on the periphery.

Trade in the barbaric Middle Ages was limited since the majority of inhabitants of Europe were serfs to feudal lords and trade routes were at risk due to widespread banditry and piracy. It was the forming of the Hanseatic League of guilds and cities interested in developing commerce and trade in the thirteenth century that opened a new chapter in city development. Traders under arms protected themselves against pirates, banditry, and feudal lords (Presbey, 1929). Cities started to blossom by the navigable rivers and around ports all over Europe, which allowed a new boost for transport and trade. The development of medieval cities slowly led to the new rise of mass advertising. It was, on the one hand, seen in the development of the graphic signs of craftsmen, and on the other, in the stationary role of criers, who stood in front of shops, and with loud voices declared the prices and the diversity of the owners' offers. Craftsmen used their apprentices for this work, and they caused a huge amount of noise in urban markets and streets (Preston, 1971, p. 9). However, the successful functioning of trade again required

wider literacy. In this connection, the biggest shift in advertising history was brought about by Gutenberg's (circa 1439) invention of the movable printing press, which enabled mass printing in a very short time. Thus, in England, history recorded the first advertisement flyer in 1477, placed on the door of the church in Salisbury, declaring the rules of behavior for priests. On a leaflet, among other things, was also written, "Pray do not pull down this advertisement" (Egan, 2007, p. 4). During this period, the use of leaflets spread, particularly in cases where they contained information that was either too clumsy for the city "criers" or required a longer presentation of the message (Preston, 1971).

Gutenberg's invention subsequently enabled the development of printing machines for newspapers, though they did not appear until more than a 100 years later. The first newspapers started in the port cities, such as Genoa (Il Sincero – 1597), Antwerp (Nieuwe Tydingen – 1605), and London (The Newes – 1622), due to the intensive trade across the seas. Only three years after the appearance of the first newspaper in England, did newspapers begin to publish the first advertisements.

Information era. The new beginnings of mass advertising were facing low levels of literacy among the population, a shortage of paper and weak distribution; therefore advertising messages were detected in leaflets, flyers, and posters much earlier than those in newspapers.

Advertisements in early newspapers were of a purely informative nature, news for themselves, mostly without titles and persuasive elements. We could compare them with today's classified advertisements. The content was largely similar: news about escaped slaves, horses, war deserters, homes and properties for sale, departures and arrivals of ships, and the first manufactured goods.

Advertisers were initially hesitant, since the circulation was often too low to achieve greater coverage of the target group. Most readers were wealthy and educated men, so there were almost no advertisements, for example, offering household items (Turner, 1952). In order to promote advertising, newspapers began to introduce innovations in the design of advertising pages. Thus, in 1726, in the United States,

Benjamin Franklin, editor of The Pennsylvania Gazette, began to introduce advertisement illustrations, distinguishing advertisements by an empty space, and also by imposing capital letters on titles. John Dunlop, in the newspaper Pennsylvania Pocket and General Advertiser (first issued in 1771), invented the slogan "It pays to advertise," with which he invited indecisive entrepreneurs to use this new form of commercial activity (Hornung, 1956). At that time, depending on the country, we also start to recognize the first attempts of advertisements to use distinctive persuasive elements.

Exaggeration era. With the development of manufacturing, trade, transport, literacy, and urbanity, advertisers realized the power of print mass media. Under the assumption that black on white is no doubt true, individual advertisers began to misuse the advertising message and to publish exaggerated and even false promises.

In the absence of any statutory regulation and self-regulatory mechanisms, as early as the eighteenth century, newspapers recorded an avalanche of advertisements for miracle products and/or patent medicines (Preston, 1971). These were products and devices that supposedly cured incurable diseases or returned beauty and youth to the old. "Patent medicines" usually were not patented, nor were they medicines (Fox, 1997, p. 16). They were, however, heavily and nationally promoted. Egan (2007) compares the strength of these campaigns with the postwar advertising of cigarettes, and notes how an individual category of products can permanently harm the reputation of the entire advertising profession. Another trend of this time was the widely used technique of slandering rivals. Advertisers were, without any fear of legal action, allowed to accuse rivals of lying and deceit (Turner, 1952).

As early as 1759, in the British newspaper The Idler, one of the first critics of advertising, Dr Samuel Johnson, commented on this problem and on the problem of advertising clutter as follows:

Advertisements are now so numerous that they are negligently perused, and it is therefore become necessary to gain attention by magnificence of promises, and by eloquence sometimes sublime

4 historical overview of advertising promise

and sometimes pathetic (Johnson in Turner, 1952, p. 29).

Doctor Johnson then added another, humorous, but meaningful assessment for our discussion: “The trade of advertising is now so near to perfection that it is not easy to propose any improvement” (in Turner, 1952, p. 29).

Advertising in this period was a tool with which you could promise whatever you wanted. Editors of newspapers at the time were differently oriented to the issue of puffery. Some of them declined to publish problematic advertisements, while some others, interestingly, charged three times the usual price for such an advertisement. Individual editors even occasionally warned their readers not to be ensnared by some offers in their newspaper (Turner, 1952, pp. 99–100). To control such advertisements, the first movement for truth in advertising arose followed by the first legal injunctions against misleading advertising. At the beginning of the twentieth century, the first acts of advertising self-regulation also appeared.

Era of differentiation. With specialization and differentiation of products, which offered many versions to meet the ever-diversifying demands of consumers, especially in the period between the two World Wars, new types of professionals entered in the preparation of advertisements, including designers, market researchers and, of course, copywriters. The first large advertising agencies in the United States were founded on Madison Avenue in New York. This was a time of aggressive sales orientation of companies. At about this time, Thomas J. Barratt, one of the pioneers of “modern” advertising, forecast such a development by bluntly stating that “Any fool can make soap. It takes a clever man to sell it” (in Turner, 1952, p. 89).

Differentiated products, highlighted with design advantages, began to communicate for themselves. They became status symbols, worthy of copying, and envy (e.g., Wedgwood ceramics in Britain). The style and design of products became more important than the product itself. Thus, the price or the durability of the products became of secondary importance, and into the spotlight stepped

fashion, style, luxury, and the freedom to choose (Leiss *et al.*, 2005, p. 52).

Advertising played an important role here as the bringer of new values, which were in conflict with the inherited traditional patterns, and as the educator of a new, individualistic human being. Advertising took a huge step toward artistic forms, encouraged by the simultaneous rise of art, music, fashion, and the film industry.

Also new was the process of advertising research, initially based on motivational research, a branch of psychoanalysis, which was brought to the United States by a Jewish emigrant from Vienna, Ernest Dichter (1964). Motivation research was to overcome the classical statistical research methods and led to the introduction of in-depth interviews, projective techniques, thematic apperception tests (TATs) and so on, based on the belief that consumers were not rational beings and advertisers needed to understand their subconscious motives.

Twitchell (2004, pp. 65–66) notes that those advertisers, as “attention engineers” at that time, understood the problems of people well and mastered the language of sincerity and consolation. The reason for these skills could lie in the fact that many of the advertising professionals in the United States came from the higher-middle class of intellectuals of the Protestant tradition. Twitchell (2004) explains that from a historical point of view, modern branding started as the men who had studied for the ministry turned their talents to selling machine-made products. “They knew the power of promise – large promise” (Twitchell, 2004, p. 65). Twitchell (2004) then lists famous people from advertising history, like Artemas Ward, pioneering writer of slogans, who was a son of a vicar, John Wanamaker, who is known for saying that half of advertising money is thrown away, we just don’t know which half, James Webb Young, who first sold Bibles door to door and later wrote a fundamental work on advertising, J. Walter Thompson, who did something similar, and later became the founder of the famous agency, and later Rosser Reeves, son of a Methodist priest, who invented the *USP* (unique selling proposition) method, which we will describe below. From this period, we can also mention one of the first modern creative copywriters, Claude Hopkins, who described his work as follows:

“I dramatize a salesman’s arguments . . . Advertising must be better than ordinary argument, just as a play must be stronger than ordinary life” (Fox, 1997, p. 54).

The era of the unique selling proposition. The post-World War II period was faced with a changed world. The giant military-industrial complex made the overnight shift to production for large crowds of consumers. The production machine began to produce huge quantities of surplus, which were needed for the new markets and new consumers. Here, advertising again played a landmark role. Under the slogans of progress and a better standard of living, the Western world faced a plethora of new products and innovations for which it was necessary to educate consumers of their availability and widest possible use. Marketers needed new assumptions about the role and functions of advertising. The answer was a new approach of how best to create the advertisement promises, namely, a *unique selling proposition* or *USP*.

The author of this approach, Rosser Reeves, was the former chair of the advertising agency Ted Bates, who argued that “consumers tend to remember just one thing from the advertisement – one strong claim, or one strong concept” (Reeves, 1970, p. 34). The argument was, in short, explained as follows:

1. Each advertisement must make a proposition to the consumer. Not just words, not just product puffery, not just show window advertising. Each advertisement must say to each reader “Buy this product and you will get this specific benefit.”
2. The proposition must be one that the competition either cannot, or does not, offer.
3. The proposition must be so strong that it can move the mass millions, that is, pull over new customers to your product (Reeves, 1970, pp. 47-48).

While logic might assume that a great innovation would tend to sell itself, without information about it, this will not happen. Reeves, in conjunction with this, commented on the well-known claim by Ralf Waldo Emerson, who once stated that when a man invents a better mouse trap,

the world will pave the road to his door. Reeves (1970) considered that the public must first learn about the innovation and thus defined the core mission of advertising in the mass media. Reeves also commented on the popular book by Vance Packard, *The Hidden Persuaders*, where he stated that advertising has nothing to do with a hidden persuasion, but that it “works openly, in the bare and pitiless sunlight” (Reeves, 1970, p. 70).

Image era. In the 1960s, both technological development and competition increased. As we have previously seen in history, after a period of innovation a number of companies with similar “me-too products” enter the market along with producers that are supporters of “leap-frog” technology, which innovate on the basis of already-existing inventions. During this time, there were two opposite paradigms in consumer perception: the industrial and the early postindustrial. The first is derived from the desire to build social status through imitating the success of others; the other from “hippy” revolutionary rejection of the old order and finding a credo in the search for the deeper meaning of life (or at least a glimpse of it). This was the ideal time for the reform of the advertising promise.

It is at this point that the history of advertising attributes the idea of the importance of brand image to David Ogilvy. Ogilvy believed that “Every advertisement should be thought of as a contribution to the complex symbol which is the *brand image*” (author’s italics) (Ogilvy, 2008, p. 128). Ogilvy believed that companies should build a brand that will stand the test of time, and that creativity was the soul of advertising. The image of the brand was considered to be a cluster of intangible properties that have no direct connection to reality. It is a kind of halo over the product or brand, which by itself may or may not be very distinctive. Thus contrary to Rosser Reeves, Ogilvy (2008) believed that consumers are not rational – what counts is the emotion; it is necessary to affect the emotional perception and not just take into account the real characteristics of the product.

The era of image in the history of advertising is associated with the so-called “creative revolution” (Fox, 1997). Although creative advertising ideas had long been present, they were dominated by the conviction of the necessity of a

6 historical overview of advertising promise

“hard-selling” approach to advertising. This approach of course did not allow ambiguity in the message, such as is for example, in the print advertising the use of indirect headlines and illustrations. These are often necessary if we want the message to possess a story or even maybe a drama. The 1960s thus brought an entirely new wind to advertising, a belief that “soft-selling” messages also work. During this time, new names appeared in advertising, such as Bill Bernbach, Helmut Krone, Julian Koenig and, of course, David Ogilvy. Their advertisements for Polaroid cameras, Hathaway shirts, Chivas Regal whiskey, Volkswagen automobiles, and so on, demonstrated that even the less-known or less-popular products and brands can achieve high visibility and brand awareness. Their success thereby justified the concept of creativity as a fundamental necessity for a modern advertising promise.

Besides the slice-of-life technique in TV commercials that was extensively used and has become a kind of synonym of the image era, one further method is well worth mentioning. It is the inherent drama of Leo Burnett. Burnett believed that advertising should be based on consumer benefits with an emphasis on the dramatic element in their expression (in Belch and Belch, 2007). Every product contains its own inherent drama, the idea or the archetype that was present at its development and launch and needs to be uncovered and creatively expressed in advertising campaigns. Some of the well-known examples of Burnett’s inherent drama approach were the Jolly Green Giant, Tony the Tiger, Marlboro campaign, and so on.

The era of positioning. In the 1970s, when there was not much evidence of the upcoming information revolution, early warnings were already emerging that the world was becoming overcrowded with marketing communications. Everyone was offering everything in more and more similar ways. The question that advertising strategists were facing at that time was how to stand out from the crowd and how to establish a distinctive position in the minds of consumers: the unique position. The authors, Jack Trout and Al Ries, advertising practitioners, used the term *positioning* in the series of articles through the year 1972. Encouraged by a positive feedback

and successful practical results, in 1981, the authors finally published the best-selling book *Positioning: The Battle for Your Mind*.

Trout and Ries started from the assumption that advertising does not work as strongly as it is was presumed to work. A solution to the problem of a less than presumed functioning of advertising was in the specific mode of “entry” into the minds of consumers, which they called *positioning*. Trout and Ries believed that people only remember the winners or those who are the best at relevant activities or competencies. The attention of advertisers must therefore shift from mere creativity to a strategy on how to establish the leading position in the market. Since not all companies can be absolutely the leader, they must look for ways to find arguments of “partial” or a specific leadership. Trout and Ries also suggested that it is possible to play on the future position, as demonstrated in the 1970s by Avis Car Rental’s famous campaign slogan “Avis is No. 2, so we try harder” (Trout and Ries, 2001).

The era of event creation. In the mid-1980s, the Western economy was facing the limits of its growth, together with additional serious warning signs of oversaturation of advertising messages. The costs to achieve the desired market outcomes became extremely high, with no guarantees about the actual success of the campaign. During this period, the belief was formed that the success of any advertising campaign should be in creating a media event. Thus, the promise gains a broader acclaim. A milestone of this era was the campaign for Apple, which, in 1984, aired the TV spot only once, during the Super Bowl. The advertisement was directed by British film director, Ridley Scott, who, in 60 seconds, presented the illusion of Big Brother from Orwell’s book “1984.” The response to this advertisement was unique. Fox (1997) reported that the next day, Apple sold \$6 million worth of the Macintosh. A number of TV stations later showed the advertisement, inviting Scott and other representatives of Apple as guests to their programs. The result was the perdurable effect of invaluable free publicity, which helped the Apple Corporation to save huge funds that would otherwise have been needed for purchasing media time and space, while leveraging the message and brand. The advertisement also won all the major awards

at advertising festivals that year, again adding additional free publicity.

The phenomenon of extending the advertisement to other media with the possibility of free publicity was, of course, followed by other advertisers. During this period, there was also an increase in the production of advertisements by well-known film directors (for example, Federico Fellini for Barilla and Akira Kurosawa for Suntory whiskey). With celebrated names and sometimes huge budgets, TV spots would hopefully be discussed and written about in the mass media. Of course, none of them ever managed to repeat the success of Apple.

Publicity could be achieved by other means, as well. The 1990s saw the advent of shock advertisements (Marconi, 1997) that tested the limits of ethical soundness (for instance, advertisements for Benetton, Diesel, Calvin Klein, etc.). *Shock advertisements* are the presentation of advertising messages that startle and offend viewers by violating norms and social values. The assumption was that negative publicity is better than none. Adding to this strategy was the belief by some that the media environment had changed drastically. The media were accused of losing a sense of measure as unpleasant scenes came into TV reports, entertainment, theater and movies. Many advertisers, in order to arouse attention in their advertisements, started to use swearing, hate speech, violence, antisocial behavior, and so on.

The era of a new social responsibility. The 1990s brought with them the need for reevaluation of advertising (Arens, 1996). A new paradigm in marketing and management was dawning, seeking more socially responsible practices by companies and more focus on ethics. Proponents of this paradigm believed that advertising should offer a serious contribution to improving society and the planet. In doing so, advertisers should come nearer to deontological or duty ethics as, for instance, in journalism and not merely follow the utilitarian ethical principles. Many advertisers responded positively, and in their advertisements began making their promises more relevant by highlighting social topics concerning, for example, the relationship between human beings and the environment. One example of this new perspective was the

aforementioned advertisements for Benetton. However, after a certain period, Benetton started to violate these manners of political correctness and embraced a discourse of shock-advertising methods in order, some believe, to generate publicity (Boutlis, 2000). The disclosure of the possibility of such intentions was no doubt harmful to the Benetton brand.

Results of the age of social responsibility cannot yet be determined, since it has not fully established itself. However, the rise of this era can be detected again in the first years of the new millennium due to the heightened awareness of ecological threats to the planet. That we can seriously talk about the age of social responsibility in advertising can be witnessed by a global initiative to promote socially responsible advertising, organized by the IAA (International Advertising Association (2008)). An interesting trend in recent years has also been the explosion in the number of “ethical” advertising agencies. The agencies are small, and presumably deal only with the advertising of those products, services, and companies that are ethically and ecologically sound. They are often committed to encouraging people to buy fewer goods that are detrimental to the environment (Gray, 2006).

Furthermore, more advertisers in developed countries today are becoming increasingly aware that it may be wiser to promise to meet higher-level needs such as those spiritual in nature rather than promoting mere material welfare. Naish (2008, p. 218) claims that status symbols for coming generations have completely changed. The new status symbols are time, space, leisure, balance, power, and autonomy. The emerging slogan could be: “I’m having a better time than you because my personal ecology’s cooler – because I know I’ve got enough” (Naish, 2008, p. 218). More is becoming too much and less is becoming sufficient. This recognition of voluntary simplicity, which is seen as a growing trend in some Western societies, is a good sign for the depleted environment of our planet.

The era of dialogue. Research into media habits and attitudes toward advertising today once again raises the question: “Is it really true this time?” As advertising clutter increases, so does

8 historical overview of advertising promise

the number of customers who are actively or passively avoiding advertising in the conventional mass media. A lack of confidence in traditional media and advertising itself is visible among generation X, and even more so in generations Y and Z (Vollmer and Precourt, 2008). These groups have many new media at their disposal so they are freed from traditional media, and are almost immune, and are far from being passive targets. They are multitasking and are “always on” (Vollmer and Precourt, 2008). In seeking the solutions for mass advertising, advertisers rely on promises that are presented as entertainment and on the use of common values, new ideologies, a sense of belonging to the group, humor, irony, and reflexivity. Also visible are shifts to the hyperreality and media intertextuality in postmodern design strategies.

There are other changes as well. Narrow-casting such as in-store media is competing with broadcasting and many new forms of communication under the approach of integrated marketing communications (IMC) have managed to usurp the previously dominant role of mass advertising.

More and more new products and services are now launched through the Web and not through conventional mass media. News now travels in cyberspace through forums and community media in the form of tweets, blogs, online videos, and so on. Communication is diffused in the same manner as the spread of viruses. Often, all that is needed is to bring in the right people who have a reputation and a large network within their communities. Advertising experts can try to initiate positive viruses, but must be careful and unobtrusive, otherwise, these efforts can backlash. Although the euphoria of modern digital advertising may be excessive, the advertising industry will nonetheless be forced to reconsider the forms of promises that are best suited to interactive situations and that include these new media. One thing is certain: what new generations require most are the dialogue, persuasive but exercisable promises, and meaningful relationships. These relationship marketing practices are in a way the reinvention of ancient practices of strong interdependence between producers and consumers.

Could all this mean that advertising has come full circle?

CONCLUSION

The history of advertising in the author's view negates the supposition that advertising is an exclusive product of capitalism. This assumption is highly obscuring for the study of the evolution and development of this interesting social phenomenon. The advent of mass advertising can be much more related to the development of cities, and hence the presence of intensive trade or exchange processes. It is, therefore, first of all an urban, cultural, and civilization phenomenon, which is dependent on the development of literacy in society and, of course, on the presence of a market economy. Advertising develops with the strengthening of all of these factors.

Through the examination of the individual eras of advertising, a series of approaches to the effective formulation of the advertising promise have been shown. Although it appears that some of the earlier approaches no longer work, the overview of contemporary advertising would show that almost all of those approaches can be seen as coexisting even today.

Before concluding, let us examine the limitations of the analysis. As already mentioned, the history of advertising was, for many periods, a less well-researched one. Thus, some authors present various pieces of information about the key turning points, but often do not cite reliable sources, so the analysis also cannot be completely definitive and is subject to further development and refinement.

The core direction of future research will seek answers to two important questions. Do the contemporary trends in society, associated with the virtual deurbanization through our Internet-connected homes and the feared rise of new illiteracy of younger generations due to the excessive consumption of images portend a bleak future for advertising and society as a whole? A new antiquity perhaps, or a new Middle Ages? Or can we be much more optimistic and dismiss such concerns as completely superfluous, since the development of modern advertising communication may bring something much

more stimulating? What the future will really bring, therefore, is yet to be ascertained.

unconscious advertising effects

Marjolein Moorman

Most traditional advertising effect models, like AIDA and DAGMAR, are based on the premise that advertising is attended to and processed consciously. However, recent neuroscientific research shows that only a small portion of the enormous amount of information that people are confronted with each day is processed consciously. Most information is unconsciously attended to, processed, and stored in memory (Lamme, 2004; Ledoux, 1998).

In the middle of last century, scientists became aware that people are unconsciously scanning their environment for relevant information continuously. Only when we encounter relevant information do we shift from unconscious to conscious attention. This shift is suitably illustrated by a well-known social psychological phenomenon called *the cocktail party effect* (Moray, 1959). The cocktail party effect takes place in information-dense surroundings, for example, a crowded party. Despite the clamor of many voices, most people are able to concentrate on one conversation at a time. It seems that they can mentally block out all the other noise. This is until their name is mentioned on the other side of the room. Most people will notice this. Apparently they are able to consciously concentrate on the conversation while unconsciously scanning the environment for other relevant information at the same time. The moment they hear their name being mentioned at the other side of the room they are likely to shift their conscious attention toward that conversation to hear what is said about them.

Starting as an evolutionary survival mechanism, unconscious processing is a very valuable human trait these days. It helps us filter relevant information out of the daily cacophony of messages calling for our attention. Where we can concentrate consciously on only one task at a time, we are able to process other information unconsciously with a seemingly unlimited capacity (Dijksterhuis, 2007). Nøretanders (1998) has estimated that of the 11 million parts of information that the human mind processes

each second, only 40 to 60 are processed consciously.

The concept of unconscious processing is very interesting for an advertising landscape that is challenged by a growing amount of messages being sent and the declining consumer attention rates. Heath (2001) poses that consumers almost never pay full attention toward advertising messages these days, because of lack of interest and a limited mental capacity to consciously process information. However, in his opinion, this does not mean that advertising is no longer effective. In fact, he poses that advertising is most effective when it is attended to and processed only on a subconscious level. The unconsciously processed brand information will have an effect on subsequent consumer attitudes and behavior, but without us being aware of it. And since we are not consciously aware, we cannot actively defend ourselves against it.

To date, the number of studies providing evidence for Heath's hypothesis that unconsciously processed advertising messages are more effective than consciously processed advertising message, remains limited. (DuPlessis, 2005, p. 141) calls this Heath's error. The problem with studying the effects of unconsciously processed advertising messages is that people are not able to remember them and that well-known advertising effect measures such as recall and recognition are thus not suitable. Physiological measures, such as fMRI and EEG scans, and implicit measures, such as implicit cognition and attitude tests, where there is no explicit mentioning of the advertisement are better suited. In the last decade, a growing number of scholars have applied these kinds of measures to study the unconscious effects of advertising. Results vary, which might be the consequence of the tests not being refined well enough to effectively study these kinds of effects. Further developments and validity tests of physiological and implicit measures are an absolute necessity to bring clarity to our understanding of unconscious advertising effects.

copy test methods to pretest advertisements

Cornelia Pechmann and Craig Andrews

In this paper, we define advertising copy testing, describe the major copy test methods using case examples, discuss each method's strengths and limitations, and identify areas of debate. The case examples were selected based on the authors' direct experiences and the methodological rigor of the methods. We define advertising copy testing as a quantitative and qualitative marketing research method that is used to pretest advertisements where numerical data on effects is collected and statistically analyzed. The key industry document about it called PACT (1982) states: "Copy testing is undertaken when a decision is to be made about whether the advertising should be run in the marketplace. Whether this stage utilizes a single test or a combination of tests, its purpose is to aid in the judgment of specific advertising executions" (page 8).

Generally, there are four stages in advertising research: (i) copy development, (ii) a rough stage, (iii) copy testing (i.e., pretesting), and (iv) tracking (i.e., posttesting) (Belch and Belch, 2007; Shimp, 2010). In copy development, initial ideas are developed from the creative brief and screened in focus groups. In the rough stage, the advertisement is tested in draft or storyboard form, again in focus groups. Next, the final or nearly final advertisements are copy tested. Finally, after appearing in the media, the advertisements are tracked using surveys and/or sales data. The surveys typically assess advertising recall and recognition, although some measure advertising attitudes, product beliefs, and/or purchase intent.

Nine principles of copy testing were developed by US advertising agencies and are set forth in PACT (1982, p. 10–27). PACT states that for a copy test method to be sound, it must (i) be relevant to the objectives, (ii) have agreement about the use of results, (iii) use multiple measurements, (iv) be based on a model of human response, (v) consider multiple exposures, (vi) test comparably finished executions, (vii) control the exposure context, (viii) define the relevant sample, and (ix) demonstrate reliability and validity. To this list, we add (x) take baseline (i.e., pre-exposure) measurements

and/or use control groups. We add this because it is in accordance with sound and generally accepted research standards (Cook and Campbell, 1979). A copy test may use a pretest design that compares participants' responses before and after they see the advertisement. Or, a copy test may randomly assign participants to a test group that sees the advertisement, or to a control group that does not, and compare their responses. Some designs make use of both approaches (Malhotra, 2009). We now describe three major copy test methods that apply these principles that are used by the US National Youth Anti-Drug Media Campaign, the US Federal Trade Commission, 1983, and the ARSgroup, a major copy test firm.

METHOD 1

The US Office of National Drug Control Policy, with the assistance of The Partnership for a Drug-Free America, has run the National Youth Anti-Drug Media Campaign for about a decade. Total expenditures are over a billion dollars (Foley and Pechmann, 2004). The antidrug advertisements target either the youth or their parents. Each advertisement is copy tested prior to airing using a method that was developed by academic experts who conduct similar copy tests for their own research (e.g., Pechmann and Reibling, 2006).

For each ad tested in a youth copy test, the sample consists of 200 Caucasians, 200 Hispanics, and 200 African-Americans, split 50/50 on grade (grades 7–8 vs. grades 9–10) and 50/50 on gender. From each ethnic group and grade, 50 youths are randomly assigned to the test group (they see the antidrug advertisement) and 50 are randomly assigned to the nonexposure control group (they do not see the advertisement). For each ad tested in a parent copy test, the sample consists of 100 Caucasians, 100 Hispanics, and 100 African-Americans, with at least one child in grades 7–10, and split about 50/50 on gender. From each ethnic group, 50 parents are randomly assigned to the test group and 50 are randomly assigned to the control group. The sample sizes were chosen to detect differences of 10% or more between test and control groups with a power of 0.80, a 95% confidence level ($p < 0.05$), and an observed within-group variance of 0.6.

2 copy test methods to pretest advertisements

The data collection is subcontracted to an experienced marketing research firm and is typically completed in one weekend using about 40 shopping malls across the United States where the firm has access to research facilities. Youth are prescreened based on grade, ethnicity, and gender and their sensation seeking is also assessed. Parents are prescreened based on their children's grades and their own ethnicity. Those who pass the screen and give informed consent are paid \$1 for completing the 10-minute study and the response rate is about 78%. Parental consent for youths' participation is obtained whenever feasible. The study is conducted in small rooms with trained English-speaking interviewers who read the questions to individual participants and record their answers. Typically multi-item scales with 5 to 10 point response options are used.

Test participants see the antidrug advertisement two times in succession, while control participants do not see it. Next, test participants answer open-ended questions about what the advertisement is about and their responses are later coded. Test participants also rate the advertisement on diagnostic measures of effectiveness, believability, attention-getting power, and argument strength. The advertisement's ratings are compared with norms from prior testing. Then, all participants complete a questionnaire that includes measures of their drug-related beliefs and intent. The measures are pretested to ensure clarity and sensitivity (no ceiling/floor effects) and are reused across multiple copy tests to ensure comparability. The data are analyzed using analysis of covariance; there is one independent variable (test vs. control condition), moderators or contingent factors (for youth: grade, gender, and ethnicity; for parents: ethnicity and gender) and several covariates (for youth: exact age and sensation seeking score; for parents: the youth's grade). The effects of test versus control condition alone and in combination with grade, gender, and/or ethnicity are examined by looking at main effects and two- and three-way interactions. This analysis is done for each belief and intent measure.

A youth advertisement is recommended for airing if it significantly ($p < 0.05$) strengthens an antidrug belief or weakens intent to use drugs among the overall sample or among a

subsample based on grade, gender, or ethnicity. It is not recommended for airing if it weakens an antidrug belief or strengthens intent to use drugs. A parent advertisement is recommended for airing if it significantly ($p < 0.05$) strengthens an antidrug parenting belief or intent among the overall sample or a subsample based on gender or ethnicity. It is not recommended for airing if it weakens an antidrug parenting belief or intent. The diagnostic measures help reveal an advertisement's specific strengths or weaknesses.

STRENGTHS

The National Youth Anti-Drug Media Campaign's copy test method seems to comply with all 10 principles of good copy testing that were outlined above.

1. *Be relevant to the objectives:* The campaign objectives are to strengthen antidrug beliefs and intent and avoid adverse effects, and the copy testing explicitly tests this.
2. *Have agreement about the use of results:* There are clear criteria for recommending or not recommending advertisements for airing.
3. *Uses multiple measurements:* There are multiple measures of the ad, beliefs, and intent.
4. *Be based on a model of human response:* Well-established models are used, such as hierarchy of effects, the elaboration likelihood model, attitude toward the ad, and steps in information processing (Vakratsas and Ambler, 1999). For example, beliefs are predicted to affect intent.
5. *Consider multiple exposures:* Participants see the antidrug advertisement twice.
6. *Test comparably finished executions:* Virtually all advertisements are tested in final form.
7. *Control the exposure context:* The antidrug advertisement is shown alone, without clutter.
8. *Define the relevant sample:* The target grades, genders, and ethnicities are stated.
9. *Demonstrate reliability and validity:* Multi-item measures are used to assess reliability. Also, copy test results are compared with tracking results to assess validity. Both reliability and validity have been found to be high.

10. *Take baseline (i.e., pre-exposure) measurements and/or use control groups:* A randomly selected control group does not see the antidrug advertisement, but just completes the belief and intent measures, and statistical comparisons are made between control and test groups. Compared with pretest designs, control groups help rule out alternative explanations for reported antidrug beliefs and intent, such as mere measurement effects and cueing of other outside campaigns simply caused by asking about antidrug beliefs and intent. In addition, a pretest design was ruled out because pretest responses are likely to bias posttest responses; the measurements are too close in time (Cook and Campbell, 1979). Specific biases of concern are that people may purposely report the same beliefs at both points in time or exhibit reactance against the testing and claim adverse effects.

LIMITATIONS

In the National Youth Anti-Drug Media Campaign's copy tests, youths' interest in drug use is not measured. Sensation seeking, which is related to drug use, is measured based on youth activities and interests (e.g., "do scary things," "explore strange places," "break rules") (Palmgreen *et al.*, 2001). Sensation seeking is included as a covariate to ensure that test and control groups are equated on it. Drug use could be directly measured so that the advertising effects could be assessed for drug user and nonuser subsamples, but this would add to the cost and sample size needs. Sample sizes are already very small for three-way interactions with just 50 participants per cell.

There is no correction for conducting multiple comparisons across the different belief and intent measures. The significance level is set at the standard $p < 0.05$, which means that on average 1 in 20 measures will show a significant effect due to chance alone, although this could be avoided by using a simple Bonferroni test (Winer *et al.*, 1991). Also, control participants do not see a control advertisement; they see nothing. It is generally recommended that control participants be given a pseudotreatment or placebo to

avoid the Hawthorne effect in which being a full research participant itself improves responses. Specifically, a control advertisement such as a nondrug public service announcement could be used and control participants could answer questions about it (Andrews and Maronick, 1995, Pechmann and Reibling, 2006). However, the control advertisement must be truly neutral. Another issue is that some involved in the campaign think that an antidrug advertisement should be aired if it works on the target group, even if it may have adverse effects on a nontarget group. However, this seems problematic because often media spills over from one group to another. Finally, some involved in the campaign think advertisements that test poorly can be fixed and aired without retesting, but retesting it helps to ensure that problems are truly resolved.

METHOD 2

The US Federal Trade Commission (FTC) has employed copy testing in advertising deception cases for over 35 years (Maronick, 1991). Although it is not required per se, extrinsic evidence such as copy testing is usually considered at the FTC and given substantial weight in cases involving potentially deceptive implied ad claims (Andrews and Maronick, 1995). Extrinsic evidence can come in the form of methodologically sound consumer research studies, such as copy tests (Kraft, Inc., 1991), marketing research, and/or expert testimony.

Generally accepted copy test principles exist at the FTC, as well as substantial case precedent for FTC copy tests (e.g., Kraft, Inc., 1991, Stouffer Foods Corp., 1994; Thompson Medical Company Inc., 1984), but how these principles are operationalized may vary somewhat in each specific case (Maronick, 1991). Such generally accepted principles for copy testing should include the following: (i) the proper universe is examined, (ii) a representative sample is drawn from the universe, (iii) the mode of questioning is correct, (iv) the survey is designed by recognized experts, (v) the data gathered are accurately reported, and (vi) the sampling design, questionnaire, interviewing, and statistical analyses are in accordance with general accepted standards for conducting survey research (Manual for Complex Litigation, 1982).

4 copy test methods to pretest advertisements

Usually, an FTC advertising deception case begins with a complaint involving interstate commerce in the public interest (Andrews, 2001). Then, discovery is undertaken to obtain ads, media schedules, marketing research, and marketing plans; and an in-house copy test might be conducted. At a later point, the FTC might conduct an outside copy test with external marketing consultants if it appears that the case might go to trial. Typically, the copy test questions are pretested, followed by a main study with about 100 participants in the test group who see the challenged advertisement, and an additional 100 in the control group who see a control advertisement instead. Participants in the control group can be randomly assigned to see (i) a purged advertisement that is identical to the challenged advertisement, but with the challenged claims removed, (ii) a different advertisement for the same brand that does not contain the challenged claims (Kraft, Inc., 1991), or (iii) no advertisement, that is, a no-exposure control (Andrews and Maronick, 1995). Data collection is usually subcontracted to an experienced firm that uses research facilities in at least three geographically dispersed shopping malls.

A standard FTC copy test begins with screener questions to ensure that the sample is representative of the universe. In the case of Stouffer Foods Corp. (1994), the sample was drawn from a universe of principal food shoppers between the ages of 25 and 54 who had purchased a frozen entrée in the last three months and were not on a medically supervised diet. Once participants are successfully screened, they are shown the challenged advertisement or a control advertisement; it is shown with two clutter advertisements. Then, participants answer the survey questions, which generally follow a “funnel approach,” beginning with general open-ended questions and then moving to successively narrower questions and ending with specific closed-ended ones (Kraft, Inc., 1991). It is important that the questions be related to the advertising claims; they cannot just measure general beliefs about a product attribute.

Hypothetically, an FTC case might be about a potentially misleading, low-fat advertising claim. After the respondents have finished looking at the target advertisement with clutter ads, a first set of questions would ask whether they

remember seeing the advertisement and the brand in question. If answered correctly, they would be asked, “What does the brand’s ad say or suggest to you about its products?” This would be followed with probes of “anything else” and would also include a “don’t know” option. Next, respondents would be asked to read the target advertisement one more time. When finished, they would be queried, “Does the ad say or suggest anything about the amount of fat in the brand?” with the response options of yes, no, and, don’t know/maybe/not sure. If the answer is “yes,” they would be asked, “What does the ad say or suggest to you about the amount of fat in the brand’s products?” with probes and don’t know options. Respondents would then be asked, “Does the ad say or suggest that the brand’s products are . . .” with the options presented as “low-fat foods,” “high-fat foods,” or “neither low- nor high-fat foods,” as well as a “don’t know” option.

Toward the end, other specific closed-ended and/or control questions may be presented. For instance, a control question is often asked involving an attribute that is not related to the challenged advertisement or the control advertisement either (e.g., about sugar in the case of challenged low-sodium claims, see Stouffer Foods Inc., 1994). The purpose of this is to help account for “yea-saying” on behalf of respondents. Lastly, demographic questions are collected. In the data analyses, the response percentages are computed, and then a net response is calculated by subtracting the responses to the control advertisement from the responses to the test advertisement. Sometimes, the respondent verbatims from open ends are summarized and presented along with the statistical results. Copy testing for corrective advertising is more involved. In the *FTC v. Novartis* case on Doan’s Pills (Mazis, 2001), the tests assessed deception, claim materiality, false beliefs, ad-belief linkages, lingering beliefs, and remedies.

STRENGTHS

The FTC’s copy test method seems to comply with all 10 principles of good copy testing.

1. *Be relevant to the objectives:* The copy testing assesses the consumer’s reasonable

interpretation and net impression of potentially misleading ad claims that are material or important (i.e., likely to affect conduct).

2. *Have agreement about the use of results:* The copy testing decision rules are consistent with generally acceptable principles, case precedent, and the 1983 FTC Deception Policy.
3. *Use multiple measurements:* A funneling process is used, from general open-ended questions to increasingly narrower questions and ending with specific closed-ended questions.
4. *Be based on a model of human response:* Copy testing is based on an information-processing model that recognizes the steps of exposure, awareness, comprehension, persuasion, and intent, though the focus is on comprehension (i.e., ad beliefs).
5. *Consider multiple exposures:* Participants see the test or control advertisement twice, once before general open-ended questions and a second time before more specific questions.
6. *Test comparably finished executions:* Advertisements are copy tested in final form, as they appeared in the media.
7. *Control the exposure context:* The test or control advertisement is shown with two clutter advertisements during the first exposure and alone during the second exposure.
8. *Define the relevant sample:* Screener questions are used to ensure that the sample is in the target market and demographics are assessed as well.
9. *Demonstrate reliability and validity:* Although single-item measures are commonly used, the funneling process allows for validity checks across measures. Also, control questions and don't know options help minimize the yea-saying bias.
10. *Take baseline (i.e., pre-exposure) measurements and/or use control groups:* Some participants are randomly assigned to see a control advertisement that does not contain the challenged claims.

LIMITATIONS

The FTC copy testing also involves tradeoffs. It can be difficult to examine low salience or

tertiary claims if awareness of these claims is low in both the open- and closed-ended questions (Maronick, 1991). Also, on occasion, there could be strong halo effects; anything in the advertisement might be considered part of the challenged claims or might immediately elicit memories of a longer running campaign. This situation makes it difficult to create a control advertisement that excises or excludes the challenged claims (Andrews and Maronick, 1995). Researchers could use a no-ad-exposure control group, but the standard FTC questions are ad specific. Also, the FTC typically uses single item versus multi-item measures, which precludes standard reliability checks (i.e., alpha). However, the funneling procedure allows for some validity assessment across measures. Finally, most data is presented in the form of simple percentage comparisons between test and control groups or between test and control questions. Thus, there could be room for more sophisticated interval-scaled measures and analyses.

METHOD 3

The ARSgroup of The Quality Measurement Company has copy tested television advertisements for over 40 years. ARSgroup has conducted over 40 000 copy tests worldwide, often for major firms such as Campbell Soup, Procter and Gamble, and Wal-Mart. It specializes in gauging the effectiveness of television advertisements based on its ARS persuasion score. Its competitors include Nielsen IAG, The Pretesting Company, and Marketing Evaluations, among others. The information below is based on published articles about ARSgroup's advertising copy testing method (Adams and Blair, 1992; Blair and Rabuck, 1998; Stewart *et al.*, 1983). Overall, the ARSgroup's copy test research shows that advertising quality, as measured by their ARS persuasion score, is related to short-term (i.e., weekly or monthly) changes in brand sales and share. Also, advertising quality is more important than advertising expenditures in affecting sales and share. Finally, a high-quality advertisement builds sales quickly, but has diminishing returns over time because its effect gradually wears out.

Typically, the ARSgroup copy tests a television advertisement in four geographically

6 copy test methods to pretest advertisements

dispersed cities (Adams and Blair, 1992; Stewart *et al.*, 1983). Approximately 400–1000 randomly selected men and women are recruited to participate ostensibly to evaluate a television pilot and are instructed to report to a research facility on a specific date and time. As an incentive, participants are told that raffles will be conducted and that many of them will win free bags of products. When they arrive, participants are shown lists of brands and are asked to choose the brand they would most like to win in each product category. Next, a raffle is conducted and some people win the products they have chosen. Then, participants view a television program in which each test advertisement is embedded along with unrelated or noncompeting clutter advertisements. At the end, participants are shown the same lists of brands again, and are asked to choose the brands that they would most like to win this time. Again, a raffle is conducted and some people win the products they have chosen. For this reason, virtually all ARSgroup copy tests involve low-cost consumer packaged goods.

The raw ARS persuasion score is calculated as the percentage of participants who choose the test brand after exposure to the test advertisement, minus the percent who chose the test brand before exposure to the test advertisement. This raw score is then converted to an adjusted persuasion score; the ARSgroup has found that the brand's market share biases the copy test responses and so this bias is removed. Three days after the copy test, participants are interviewed by phone to assess advertising recall (Stewart *et al.*, 1983), but the main measure used to evaluate advertisements is the adjusted ARS persuasion score. The ARSgroup's reliability studies indicate the adjusted persuasion score's test-retest reliability is 0.93 (Stewart *et al.*, 1983). Its validity studies show the adjusted persuasion score predicts trial rates for new, frequently purchased, branded consumer goods ($r = 0.85$). ARSgroup has also validated its copy test method for established brands in split cable ad tests, meaning some households receive the advertisement while others do not, and household purchase rates are compared (Adams and Blair, 1992).

STRENGTHS

The ARSgroup method generally complies with the 10 principles of good copy testing.

1. *Be relevant to the objectives:* The ARSgroup objective is to predict an advertisement's effect on brand sales and share; its validation studies indicate that it does this.
2. *Have agreement about the use of results:* ARSgroup's recommendations are clear—ads with low ARS persuasion scores should not be used because they will not improve sales no matter how much they air.
3. *Use multiple measurements:* The ARSgroup measures product choice as well as advertising recall.
4. *Be based on a model of human response:* There is no explicit model of advertising response.
5. *Consider multiple exposures:* Participants see an ad just once, but the ARSgroup's validation studies suggest this is sufficient (Adams and Blair, 1992; Blair and Rabuck, 1998).
6. *Test comparably finished executions:* The ARSgroup copy tests television ads in final or near final form; it does not test storyboards.
7. *Controls the exposure context:* The exposure context is carefully controlled. The advertisements are embedded in the same television program with the same clutter advertisements across multiple copy tests.
8. *Define the relevant sample:* A general audience sample is used, but most of the copy tests are for general or mass-market products.
9. *Demonstrate reliability and validity:* The ARSgroup has demonstrated reliability and validity.
10. *Take baseline (pre-exposure) measurements and/or use control groups:* The ARSgroup takes a pre-exposure measure of brand choice and uses this as the baseline for assessing the advertisement's persuasive impact on brand choice.

LIMITATIONS

The ARSgroup does not disclose the adjustments they make to the raw persuasion score to correct for response biases because of brand

market share; their adjustments are proprietary. This makes it difficult to fully evaluate the method and to publish ARSgroup studies; most academic journals require that measurement adjustments be disclosed. This proprietary approach also prohibits independent replication of the ARSgroup validation studies. In addition, many copy test participants receive the products they choose and so the advertised products must be low-cost consumer packaged goods. The ARSgroup method cannot be used for expensive items such as cars, or for illegal items such as marijuana. Since a representative sample is employed, the products must have reasonably wide appeal.

Areas of debate. There are many general areas of debate about copy testing. The main ones are (i) the reliance on convenience samples such as people in shopping malls, (ii) the artificial viewing environment including forced exposure to the advertising, (iii) no assessment of cumulative advertising effects, (iv) often no measure of actual behavior, (v) no assessment of advertising-induced word of mouth, and (vi) the increased use of on-line or web-based copy testing, which means less control over samples and exposure environments, although the effective use of screeners can help. A longstanding concern is the reliance on malls and other public venues that offer convenience samples. However, convenience sampling is common in marketing research and the US courts have accepted it (Maronick, 1991; Plevan and Siroky, 1991). The artificial viewing environment is of concern and so many copy tests include clutter. The FTC shows the test advertisement with two clutter advertisements and then measures awareness of it. The ARSgroup embeds the test advertisements with numerous clutter advertisements.

Copy tests typically offer no assessment of cumulative advertising effects, but most ensure that consumers have seen the test advertisement at least twice. Research suggests that an advertisement generally has its impact after just two or three exposures (Pechmann and Stewart, 1988). The ad's effect on actual product use or purchase behavior should be measured whenever possible, if this is relevant to the copy test objectives. The FTC copy tests often aim to measure false advertising beliefs. For other copy tests,

behavior can often be measured if the budgets are adequate and the test advertisements promote low-cost consumer goods. For expensive items such as cars, illegal items such as marijuana, and high-risk items such as cigarettes, it can be very difficult to assess behavior. In such cases, it is important to use validated intent measures.

Copy tests generally do not measure word of mouth effects, for instance, when one person talks to another about a memorable advertisement. Word of mouth may produce either positive or negative outcomes. The ARSgroup's copy tests involve large groups of people who could be permitted to talk about the ads, but this would likely be too contrived. Internet postings may be a better way to assess word-of-mouth advertising effects. Also, a recent concern is that on-line or web-based copy testing might be less valid than traditional mall-based methods. People who participate in on-line copy tests may be less representative than people in malls, although effective screeners can help in this regard. Yet, the on-line environment can be less controllable than a mall facility; for instance, people on-line can talk to others and/or multitask while completing the survey. More research is needed to compare on-line versus mall-based copy tests.

In summary, copy testing is a standard and well-accepted marketing research method that has been shown to be reliable and valid if it is done well. Companies and other entities should feel confident about using copy testing to evaluate advertisements as long as the recommended procedures discussed above are followed.

sex in advertising

Tom Reichert

Few topics in marketing prompt as much interest as sex in advertising. Salacious ads can generate hundreds of blog posts and coverage from traditional media such as CNN and ABC News. Sometimes the advertisement leads to increased sales, and other times it results in consumer complaints and a swift apology as the ad is promptly pulled off the air. Regardless of the result, advertisers have used sexual imagery and themes to promote their products since the earliest days of marketing and will continue to do so in a quest for sales.

DEFINITION

Sex in advertising is often defined as “sexuality in the form of nudity, sexual imagery, innuendo, and double entendre . . . employed as an advertising tool for a wide variety of products” (Courtney and Whipple, 1983, p. 103). Research indicates that the vast majority of sexual content in advertising consists of images of sexually appealing models—models who adhere to ideals of Western beauty standards (Reichert, 2003). Often the models are clothed in a revealing manner and posed or behaving—either by themselves or with other models—to stimulate sexual thoughts and feelings within viewers (see Figure 1). Lighting, pacing, editing, setting, and other aspects of the prevailing tone contribute to the sexual nature of an advertisement. Verbal elements also contribute to sexual meaning such as sexually suggestive phrases and intonation, or headlines with double meaning that may seem innocuous until paired with a provocative image.

Sexual content within an ad may or may not be relevant to the product category or advertised brand message. For example, some ads feature images of scantily clad women or men making eye contact with the viewer but with no logical connection to the advertised product. A Carl's Jr. commercial aired in 2005, for instance, featured a swimsuit clad Paris Hilton seductively washing a Bentley and taking a bite from a hamburger. More often, however, sexual content is central to the brand's message. For example, advertising can tell consumers that the brand will enhance

Figure 1 Nudity is clearly present in this marketing image for youth clothier Abercrombie & Fitch. (reproduced by permission of Sam Shahid).

their beauty or chances for romantic success. Commercials aired in the 1970s for Prince Matchabelli's *Wind Song* perfume positioned the fragrance as a romantic attractant with the memorable jingle, “I can't seem to forget you. Your *Wind Song* stays on my mind.” In a typical commercial, a woman sprays a napkin with *Wind Song* for the waiter to deliver to her boyfriend across the restaurant. Immediately, her boyfriend appears and bestows a romantic kiss. Most recently, men's toiletry brands such as *Axe* and *Old Spice* position their body sprays and deodorants as a key to attracting females.

In the late 1960s, there was growing concern regarding subliminal uses of sex in advertising. Advertisers were accused of inserting virtually undetectable phallic symbols or words such as “SEX” into ads that are processed by the sub- or preconscious mind. Following exposure, consumers find themselves drawn to these brands without realizing the connection to hidden sexual content. Much of the interest in this topic is attributable to Key's (1973) best-selling book, *Subliminal Seduction*. Advertisers counter that they can hardly gain consumer attention by using readily perceptible words and images, much less hidden symbols. Marketers also argue that at no point in the ad-creation process is a request made to insert subliminal sexual content.

EFFECTIVENESS

Since the 1960s, academic researchers have sought to determine if and how sexual content works when used in advertising. Overall, findings indicate that sex in advertising is

particularly adroit at getting noticed (Belch *et al.*, 1981; Percy and Rossiter, 1992). In other words, sex in advertising achieves a high level of attention. A distraction effect can occur, however, such that attention is directed toward the sexual content instead of the brand message or sponsorship information (Severn, Belch, and Belch, 1990). As a result, sexual ads get noticed and are likely to be remembered, but consumers may not recall what was said or what brand was advertised.

Findings also reveal that sex in advertising generates an emotional response within viewers (LaTour and Henthorne, 1993). Arousal is more pronounced as the explicitness of the sexual content (i.e., nudity) increases. Similarly, explicitness is also linked to the degree a viewer likes or dislikes an ad. Recent research shows that some personality characteristics such as sensation seeking and sexual schemas influence how a consumer will respond to sex in advertising (Reichert, LaTour, and Kim, 2007).

While some advertisers only use sex to grab attention, many use it as a selling point for their brand. One study found that most examples of sex in advertising contain a brand-related message that buying the brand will result in the purchaser being more sexually attractive, getting more sex or better sex, or experiencing sexy feelings that will boost one's self confidence (Lambiase and Reichert, 2003). Any distraction effect may be mitigated if one of these sexual brand promises is a central theme of the ad. However, credibility—whether consumers actually believe the advertiser's promises—is important to consider as well.

As described previously, relevance between sex and the advertised product influences the effectiveness of the ad. Research typically shows an advantage in terms of memory, likability, and purchase intention when sex in advertising is used for products with a reasonable connection to sex (Percy and Rossiter, 1992). Typical product categories generally viewed as relevant to sex in advertising include fashion, fragrance, tobacco, and alcohol. A logical connection can be made to other products or brands but effectiveness is reduced, the further the connection between the product and sex.

While somewhat stereotypical, women and men often respond differently to sex in advertising (Reichert, LaTour, and Kim, 2007). For example, whereas men are less likely to be turned off or offended by a gratuitous ad, there is evidence that women respond more positively to images of couples and romantic settings. Perhaps, not surprisingly, both women and men respond more positively to images of the opposite sex compared to images of the same sex.

HISTORY AND PREVALENCE

Early uses of sex in advertising date back thousands of years (Reichert, 2003). Painted signs for brothels intended for weary sailors have been discovered in port towns along the Mediterranean. As early as the 1800s, classical images of nude or semiclothed women appeared in posters and handbills designed to attract the attention of male patrons. In 1912, the J. Walter Thompson (JWT) agency claims to have invented the “sexual appeal” in ads for Woodbury's Facial Soap. Its ads featured beautiful women accompanied by adorning men. The tagline, “The skin you love to touch,” made it clear that buying and using Woodbury's soap was the key to love and romance. Whether JWT truly invented the sexual appeal or not, such appeals—the promise of attracting a mate—continues to be a commonly employed appeal for many types of socially consumed products.

In the 1960s, sex in advertising migrated from the pages of men's and women's magazines to network television. For example, a commercial for Noxema shaving cream aired in 1966 featured Gunilla Knutson, a former Miss Sweden, telling men to “Take it off. Take it all off,” while “The Stripper” score played in the background.

Calvin Klein fashion ads generated media attention from 1979 to 1995, and today, for sexual ad content that often crosses the line of social acceptability (Gaines and Churcher, 1994). For example, commercials in 1981 featured a then 15-year-old Brooke Shields teasingly uttering double entendres such as, “Know what comes between me and my Calvins? Nothing.” Klein subsequently introduced his men's and women's intimate-wear lines with beautiful models clad only in underwear—not as

Figure 2 In the 1980s, nudity in Calvin Klein ads pushed the limits of acceptability in the United States. (reproduced by permission of Sam Shahid).

common an occurrence as in today's advertising—in huge outdoor ads in Times Square. His ads in the 1980s and 1990s for his designer fragrances, especially *Obsession*, featured nude models in idyllic scenes (see Figure 2) or in steamy ménage-a-trios settings. And in 1995, Klein again generated controversy with a campaign featuring underage models filmed in what appears to be a basement. Many critics claimed that the commercials contained a pedophilic theme. Although controversial, over the years, the ads and the attention Calvin Klein garnered often resulted in at least a short-term sales increase.

Today, sex in advertising is relatively common. Studies indicate that up to 10% of network and cable television commercials contain sexual content (Hetsroni, 2007). To lure viewers, up to 25% of network promos—the ads networks air to promote their programming—contain sexual scenes. Overall, sexual themes and images are more likely to appear in men's and women's fashion, beauty, and general-interest magazines (Soley and Reid, 1988). Online ads contain sexual content as well; up to 20% of banner ads on the most popular news and sports sites contain images of physically attractive models. In addition, websites can contain sexual images on the site or within on-line video. For example, in 2009, Hollister, a clothing brand for teens and young adults, featured partial nudity and intimate scenes in streaming video for its brand of intimate wear. It is

doubtful that the video would have cleared any mainstream TV network's standards board.

CRITICISMS

Sex in advertising generates criticism within the profession and by social critics. Generally, advertising professionals do not respect the use of sex in advertising. Many creative people within the advertising business consider its use a lazy way to grab attention. David Ogilvy said it this way: "Some copywriters, assuming that the reader will find the product as boring as they do, try to inveigle [the viewer] into their ads with pictures of babies, beagles and bosoms. This is a mistake" (Ogilvy, 1985, p. 139). Industry professionals believe that advertising should appeal to people's higher motivations and attempt to uplift people, not speak to their lowest, most base, motives.

Socially, sex in advertising is criticized because of its slanted depiction of women. While some ads feature "beefcake" images of men or healthy images of couples, most sexual ads feature images of women portrayed as objects of desire (Hetsroni, 2007; Soley and Reid, 1988). Feminists object to these one-dimensional images because they contribute to the impression that a woman's value resides in her physical attractiveness and ability to attract a man. A related concern is that pornographic themes such as bondage and related fetishes are showing up in mainstream advertising. Pornographic or not, many people consider sexual content offensive and intrusive, and resent seeing it in a commercial when viewing television with the family—especially when children are present.

Despite these criticisms, some marketers continue to employ sex in advertising to get their products noticed and to convince consumers that their brands can enhance consumers' relational intimacy and satisfaction.

viral marketing on the Internet

Petya Eckler and Shelly Rodgers

DEFINITION

Viral marketing applies traditional word-of-mouth (WOM) marketing to the online environment. Much confusion exists about its actual definition, as the terms viral marketing, stealth marketing, buzz marketing, and viral advertising have been used interchangeably (Golan and Zaidner, 2008). The authors define *viral marketing* as a broad array of online WOM strategies designed to encourage both online and peer-to-peer communication about a brand, product or service (p. 961). These include, but are not limited to, viral videos, email messages, use of online social networks and online forums, text messaging, interactive microsites and online games, blogs, podcasts, and so on. *Viral advertising*, on the other hand, is a subset of this larger umbrella and is defined as unpaid peer-to-peer communication of provocative content originating from an identified sponsor using the Internet to persuade or influence an audience to pass along the content to others (Porter and Golan, 2006).

HISTORY

The term *viral marketing* is credited to venture capitalists Steve Jurvetson and Tim Draper who used viral to describe the marketing techniques behind Hotmail's growth in 1996. The catalyst for success was the promotional tag on each outgoing email, which turned subscribers into company salespeople who took the message to their own WOM networks (Jurvetson and Draper, 1997). Thus, the viral message spread organically with spatial and network locality, much like a virus, and garnered 12 million subscribers in 1.5 years for less than \$500 000 (Jurvetson and Draper, 1997). Since then, viral campaigns have become increasingly popular.

UNIQUE FEATURES

Unique to viral marketing is its focus on the message, not the product. Thus, the brand is often secondary in viral videos, as they aim to

look more like entertainment pieces and less like branded commercials. The success of a viral campaign can be attributed to its emotional or entertainment value rather than information about the brand or product (MindComet, 2006). Appeals related to humor, sexuality, nudity, and violence are more common as compared to television ads (Porter and Golan, 2006). More extreme appeals are often needed because viral ads must prompt "forwarding" behavior not just awareness or liking, as with traditional advertising.

In viral campaigns, initial exposure is achieved through seeding, which "plants" the message in selected consumers, who then spread it to their social networks. Seeding decisions depend on the target audience for each campaign (MindComet, 2006).

Similar to other marketing tools, viral marketing has unique benefits and drawbacks. Advantages include the following:

- reduced cost of promotion because of free peer-to-peer distribution and eliminated media buys;
- increased credibility due to friends' endorsement (Chiu *et al.*, 2007);
- increased visibility as messages cut across media clutter (MindComet, 2006);
- decreased interruption as viewers choose the time and place to view viral messages (MindComet, 2006); and
- improved format flexibility as messages can take various forms.

Viral marketing disadvantages include the following:

- reduced control of the marketer, as a viral campaign relies on consumers to spread it;
- increased reliance on consumers' motivation to spread the message for campaign success;
- increased risk of negative reactions as viral ads may become too unconventional.

Effective viral marketing depends on consumers' forwarding behavior; therefore, understanding consumer motivations is vital, as is research on the content features that motivate consumers and the consumers most appropriate for initial seeding. As with other marketing tools, viral approaches must be integrated into the

2 viral marketing on the Internet

MARKETING MIX and typically are not a stand-alone promotional strategy.

advertising media selection and planning

Marjolein Moorman, Peter C. Neijens, and
Edith G. Smit

INTRODUCTION

Media are essential in the communication of brands with their target groups. After all, a splendid commercial is ineffective if it does not reach its audience. A media strategy for a brand involves the selection of media types (e.g., newspapers, television), vehicles (e.g., Home and Garden, Friends), and media units (e.g., a full-page, full-color, back page ad in the December issue). Other subjects that should be dealt with in the media plan are timing (when a message should be communicated) and frequency (how often).

Media (any transmission vehicle or device through which communication may occur) can take many forms. In a broad sense media include not only traditional (mass) media, such as broadcast media (TV and radio), print media (newspapers and magazines), out-of-home media (posters, billboards), new media (Internet, games, mobile phone), but also events, sponsored persons, retail outlets, and sales persons. This contribution focuses on traditional and new media.

Media decisions are important as media are by far the biggest debit entry in a campaign. According to a study by the Advertising Research Foundation (2002, cited in Kelly and Jugenheimer, 2004, p. 4), not less than 80–85% of the costs of an average campaign is spent on buying advertising space. The other 15–20% is used for research, development of the commercial, production, and evaluation.

Media decisions have become more complicated, more extensive, and thus more interesting in the last decades because of considerable changes in the media landscape. These changes include an enormous growth in the media offer, in traditional media as well as new media such as the Internet, mobile phones, and games. This growth gives unprecedented opportunities, but poses problems as well because target groups are fragmented across media. For example, in 1995 there were 225 shows in British television that reached audiences of over 15 million, but by

2005 there were none (FEN (Future Exploration Network), 2007, p. 4). Another problematic aspect of the new media landscape is the advertising clutter that has grown to unprecedented levels. For instance, today an average television viewer in the Netherlands is exposed to 17 minutes of daily commercial viewing, compared to 5 minutes in 1990. The advertising clutter makes it more difficult for advertisers to attract attention to their messages and generate advertising effects. Another factor that complicates the life of media planners is the shift in control over brand communication from advertisers to consumers, instigated by new, interactive media.

In this article we discuss the factors that play a role in the selection and planning of media in a campaign. First, we discuss key concepts (reach, frequency, timing, and costs). Then we pay attention to audience and medium factors that influence media impact. Finally, we discuss developments in new and traditional advertising media (see BUSINESS-TO-BUSINESS MEDIA SELECTION).

KEY CONCEPTS

Reach. The basis currency in media planning is the number of people being *reached* by an advertising message carried by a particular media vehicle. For broadcast media, the term *ratings* is used. It is common to make a distinction between different indicators of reach (see Harvey, 1997) such as vehicle distribution, vehicle exposure, advertising exposure, ad attentiveness, ad communication, ad persuasion, ad response, and sales response. Advertising exposure – “the number of target audience individuals exposed to the advertising” (Rossiter and Percy, 1998, p. 447), also defined as *the number of people with open eyes/ears in front of advertising space* – is generally considered to be the most valid indicator for reach. Other frequently used indicators such as vehicle distribution and vehicle exposure are less accurate estimations of advertising reach. Moreover, “deeper concepts” such as persuasion and behavioral responses are not appropriate because these are affected by factors beyond the control of the media, such as the power of the ad and the attractiveness of the bargain offered in the ad (see ADVERTISING EFFECTIVENESS).

2 advertising media selection and planning

Media planning terminology contains a variety of reach-related concepts. *Current reach*, for example, indicates the number of people reached within the publication interval of a title (a day for dailies, a week for weeklies, etc.). Another concept is *selectivity*, which expresses the number of target group people that are reached compared to the total number of people reached. The higher the selectivity of a medium, the lower the *waste* (i.e., reach of people that do not belong to the target group). A third example in this respect is *effective reach*. This concept indicates the number of target audience individuals reached at the effective frequency level (is dependent on a particular campaign, e.g., three exposures or more; see section Frequency below). Other metrics include, for example, *ad impressions* for interactive advertisements (see www.iab.net).

Advertising reach is rarely evaluated on the level of an individual message, but is done mostly on the level of the campaign as a whole. Campaign reach indicates the number of *contacts* with all the published advertising messages in the campaign. To illustrate this concept: if one person is exposed to three commercials in a row, the campaign has generated three contacts. We have the same number of contacts if three people are exposed to one commercial each. We call the total number of contacts with a campaign *gross reach*. The *net reach* in a medium plan is the number of people that are exposed to the campaign at least once. In other words, gross reach minus the *overlap* (i.e., repeated exposures). In both examples, the gross reach of the campaigns is 3, but the net reach is 1 and 3, respectively.

For broadcast media, gross reach is usually expressed in *Gross Rating Points* (GRPs). A value of 100 GRPs means that the campaign has a number of contacts that is equal to 100% of the target audience. That does not necessarily mean that all target group members are reached. It may mean that 50% of the target group is reached twice, in other words: 50% of the target group has a (average) contact frequency of 2. GRPs are an estimate of the total number of exposures per 100 target audience members in an advertising cycle, without taking into account if these are unique or repeated exposures. We can express this in a simple formula: GRPs =

net reach \times average frequency. This formula illustrates that a media planner has to make a trade-off between “reach” and “frequency,” because the same budget can be used to reach as many people as possible (“how many”), or used to confront a (smaller) audience as often as possible (“how often”).

It may be noted that a campaign generates a frequency distribution of contacts: in a campaign that aims to reach people three times on average, some individuals will have one contact with the campaign, others two, five, or seven, and so on. That complicates the decisions of the media planner. The size of the overlap between the reach of the various medium vehicles in a campaign determines to what extent more insertions of a particular medium vehicle lead to a higher reach or to a higher contact frequency.

Frequency. How often should people be reached with a message? Decisions with respect to frequency of exposures are important because media costs are high and campaigners want to avoid wasting money due to too little insertions (lack of effects) or too many insertions (unnecessary costs). Most theories that specify a relationship between frequency of exposures and campaign effects (the so-called response curve) assume that repeating the message is useful because it adds to the effects of the campaign (wear-in). After a certain number of repetitions the effects decline, or can even become negative (wear-out). However, theories differ strongly with respect to the supposed shape of the response curve and the optimal frequency. The frequency debate was especially vigorous in the last three decades of the twentieth century. We will discuss a few well-known frequency theories from that time in chronological order.

One of the most influential theories on the optimum number of exposures is the *three-hit theory* of Herbert Krugman. According to Krugman (1972), a cognitive reaction dominates the response of the audience during the first confrontation with a commercial. The receiver asks himself: “What is it? What is it all about?” During the second confrontation, an evaluative reaction dominates: “What is in it for me?” The third confrontation is the real reminder. The viewer knows what

it is all about and can take action. Krugman discusses *proven exposures*. According to him, it is possible that a commercial brings the receiver to his second response (“What is in for me”) after, for example, the twenty-third confrontation.

Naples (1979) presented a literature review on the authority of the American *Association of National Advertisers (ANA)* entitled *Effective Frequency: The Relationship Between Frequency and Advertising Effectiveness*. His conclusions were: “One confrontation with an advertisement has no or little effect, except in extraordinary circumstances. Two confrontations (within a purchase interval) is effective. The *optimal* frequency is at least three confrontations within a purchase interval”.

On the basis of analyses of Nielsen-panel television viewing and buying behavior data, John Philip Jones concluded in 1995 that the first blow is half the battle. He stated that a successful campaign is effective from the first confrontation. In other words, the response curve has no threshold. He also concludes that the first confrontation will have the greatest effect and that the next confrontations will have less effect (diminishing returns): the response curve is convex. Critics of Jones have brought forward that he had only looked at short-term effects of established brands in the fast-moving consumer goods (FMCG) sector and that his conclusions therefore had limited validity.

McDonald (1996) wrote a follow-up of Naples’ review and came to other conclusions. He subscribed to Jones’ ideas with respect to the short-term effects of advertising for established brands. However, he concluded that new messages, for new brands, do show a threshold. Furthermore, the shape of the response curve depends, according to McDonald, on a number of factors. In other words, there is not one rule only for optimal frequency. The following factors have an influence on the shape of the response curve: activities of competitors, share of voice, market share and status of the brand, the quality of the advertisement, the time until the purchase, the target group, and the type of product.

Timing. Timing is another important media planning decision, which relates to the length

and moment of the campaign period. A choice has to be made between “bursting,” flighting, or pulsing (large media exposure over a short period) on the one hand and “dripping” (spreading small exposure over time) on the other hand (Heflin and Haygood, 1985). Heflin and Haygood concluded that media schemes with an average concentration showed the best results. They explain the bad results of the high intensive schemes because these irritate and satiate the audience. The bad results of the very low intensive schemes were explained by cognitive constraints (“forget effect”). According to Ligthart (1999), the answer to the question “*bursting or dripping?*” depends on a number of factors. First, if a large audience can be reached quickly, then a burst is preferred. Second, dripping is more effective for messages that are forgotten quickly because, for example, many competitors are advertising, the ad stock is low, or the quality of the commercial is poor.

A final factor is the budget. When the budget is substantial, an effective combination of bursting and dripping (“maintenance”) is possible (Ligthart, 1999, p. 56).

Other timing decisions concern the period of the year in which to advertise: the season, the week, the day, and the time of the day. Moreover, advertisers have to decide when to advertise in relation to competitors in the market: simultaneous or not. An important criterion here is the possibility to get a high *share of voice*, which is important for the visibility of the brand. A high share of voice depends on the relative amount of money that an advertiser can spend.

Cost. In the selection of media for a campaign, costs play an important role. Several metrics are used to express the costs: absolute cost, cost per 1000 persons reached (CPM), cost per GRP (CPP, cost per rating point). In the Internet context, variants include cost per click through (CPT or CPC), cost per lead (CPL), cost per sale (CPS), cost per impression (CPI), pay per sale (PPS), or pay per purchase (PPP). Rate cards usually mention gross costs. Big advertisers and media agencies are often able to negotiate substantive discounts (net cost) (see COMMUNICATIONS BUDGETING; THE ADVERTISING BUDGET).

IMPACT FACTORS

Media differ in their ability to get a message across. The impact of the message may differ as a consequence of medium characteristics or audience reactions toward the medium.

Medium characteristics. First, media differ with respect to the number and type of modalities such as text, audio, pictures, and video. Television, for example, uses video, colors, and sound. This makes the medium highly suitable for the communication of emotions and the demonstration of products. Obviously, a billboard is much more restricted in this respect. Other characteristics that influence the impact of a medium are, for example, the format and the use of color.

Second, we can make a distinction between push media (also called display or delivery media) and pull media (also called search or retrieval media) (Dijkstra, Buijtel, and Van Raaij, 2005). Push media, such as television or radio, are media where the sender determines what is on offer and when. Pull media, such as print media or the Internet, are media where the receiver actively selects the message. These media require active and involved participants. Push media may be better suited for products and brands that are not (yet) in the consideration set of the consumer, or at the top of the response hierarchy.

Third, media also vary to the extent to which the audience can influence the pace of the information flow. *Internal pacing* (the receiver determines) is high for magazines and newspapers, and low for radio and television (external pacing, the medium determines). A medium with internal pacing is better suited for complex messages and for products and services for which consumers actively search information, because the consumer can adjust the pace of the information consumption to the complexity of the message.

Fourth, the amount of reach and the speed of reach accumulation differ between types of media. Television and out-of-home, for example, are characterized by the fast and large accumulation of reach, in contrast to, for example, magazines.

Audience responses. Audiences react differently to different media. Krugman (1965), for example, describes print media as “hot” media,

requiring active engagement of the readers, while he considered broadcast media as “passive” or “cool” media with less involved audiences.

Audience involvement may not only differ between medium types, but also between media vehicles. This aspect is, amongst others, studied in so-called medium context studies. The medium context concerns the environment of the ad provided by the vehicle carrying it, such as a television program, an issue of a magazine, or an Internet site. A distinction can be made here between editorial context and commercial context. Studies on commercial context have predominantly concentrated on the effect of the amount and nature of other commercial messages in the environment of an ad, referred to as *clutter* and *competitive clutter*. It has been shown that as the number of ads in the environment of the target ad increases the effectiveness of the target ad decreases, especially when the other ads are directly competitive (Kent, 1995).

Studies on editorial context have shown time and again that the same source delivering the same message to the same audience on separate occasions produces different effects depending on the differing programming or editorial contexts in which the message appears (Norris and Colman, 1992). In particular, context-induced psychological responses, such as involvement elicited by a documentary, happiness caused by a sitcom, or sadness generated by a drama series, are considered to have an important impact on advertising processing (Moorman, Neijens, and Smit, 2005). At the heart of the theoretical explanations for the influence of context-induced psychological responses on advertising processing lies the assumption that mental reactions toward the editorial context do not cease when the editorial content is interrupted by advertisements, but that these reactions “carry over” to the advertisements. These carried-over reactions, in turn, influence advertising processing. For example, it has been frequently found that advertisements placed in editorial contexts which induce positive feelings are evaluated more positively. Furthermore, it has been shown that context-induced involvement has an influence on attention for advertisements and memory for advertisements.

Attitudes of media users toward the medium (vehicle) and advertising in the medium are also a source of influence. Media vehicles may be seen by their viewers or readers as authoritative, credible, reliable, or undependable. Advertising in some media vehicles, for example, in do it yourself programs or magazines may be appreciated more than in others. Some media vehicles attract audiences that are ad lovers, and others have a greater group of ad avoiders (Smit and Neijens, 2000) (*see* ATTITUDES).

Situational circumstances in which a person is exposed to an advertisement are also important for the impact of a medium. This includes the person's physical environment (e.g., "at home, at the kitchen table"), the social environment (e.g., "in the company of three family members"), the time frame ("during breakfast"), and the mental state a person is in prior to exposure to the medium content (e.g., "an early morning mood"). Although it has been shown that each of these aspects can influence advertising effectiveness substantively, receiver context aspects are less relevant for media planning because planners have no ways of influencing them.

NEW DEVELOPMENTS

New developments in advertising media can be characterized as more multimedia, targeted, customized, and personalized as well as integrating advertising and transaction.

Multimedia. Many campaigns make use of more than one medium. In these cross-media or cross-tools campaigns, marketers seek to maximize the effectiveness of their budgets by exploiting the unique strengths of each medium and tool and by maximizing cross-media consistency and synergies. As Ephron (2000) stated: "Old media planning was about picking individual media. New media planning is about picking combinations of media (and permutations of media, where sequence of exposure is important)." (*see* INTEGRATED MARKETING COMMUNICATION STRATEGY; MULTICHANNEL MARKETING; INTEGRATED MARKETING COMMUNICATION).

One of the biggest challenges in advertising research these days is finding an answer to the question as to how each medium in a multimedia campaign contributes to the campaigns

impact. An answer to this question is not easily found. Data from standard industry audience measurement studies do not offer a sufficient answer, because these studies are traditionally focused on measuring just one type of medium. This inhibits insight into the overlap between people's use of various media. Consequently, we cannot learn from these data which medium has produced the biggest effect.

A related, perhaps even more challenging, question is how each medium in a multimedia campaign enhances the contribution of other media. This question is driven by "the potential existence of synergy, that is, the added value of one medium as a result of the presence of another medium, causing the combined effect of media to exceed the sum of their individual effects" (Naik and Raman, 2003, p. 385). The question of synergy is, in other words, whether the combined effect of multimedia activities, such as television, radio and print, is greater than the total sum of their individual effects.

Various theories have been put forward in literature (e.g., Dijkstra, Buijtsels, and Van Raaij, 2005) with respect to which synergetic effects from the use of multiple media in an advertising campaign can be expected. First, the *encoding variability theory* suggests that when a message is received through a variety of media, the information from the message will be encoded in memory in a more complex fashion than if the message was only received through one medium. The resulting information network in the brain will consequently be stronger, clearer, and more accessible, which enhances the likelihood that the information will be recalled accurately. Second, the *credibility principle* suggests that a message is perceived as more believable when it is received through multiple independent sources. Third, the *transfer hypothesis* proposes that the perception of an advertisement in one medium may be enriched by a previous encounter with the advertisement in another medium. For example, the images seen in a television commercial may be brought to mind when one hears the brand's jingle in a radio commercial (visual transfer), or the brand's jingle may be remembered when one sees a billboard along the highway (audio transfer). Or the other way around: a second confrontation with a message enriches the first impression (backward transfer).

Fourth, based on the *complementary principle* it can be expected that “synergy occurs when different media with their specific strengths complement each other in a campaign or when the strength of one medium compensates for the weakness of another medium” (Dijkstra, Buijtsels, and Van Raaij, 2005).

On the basis of these four theories, it can be expected that multimedia campaigns are more effective than single media campaigns. It is not surprising therefore that most practitioners and academics share the belief that using multiple media tools is efficient, rather than extravagant or redundant. However, empirical evidence supporting this contention has been scarce until date.

New media. New media include digital media such as the Internet, mobile phones, digital games, and so on. These media offer a large number of advertising possibilities varying from the more “traditional” display ads (such as online banner ads, bumper ads before movies, e-mails) to advertising forms that reflect the new possibilities of digital media. New media’s interactivity makes it possible to tailor advertising to the individual consumer, and to integrate transactions with communication. Search engine ads, for example, are ads shown in connection with search engine results. These ads are often as relevant for the consumer as the content they are searching for (*see* DIRECT AND INTERACTIVE MARKETING; E-COMMERCE AND INTERNET MARKETING).

Digital media make it also possible for audiences to create and communicate brand information on a large scale. With the emergence of consumer-generated media platforms, word-of-mouth conversations have migrated to the World Wide Web, creating a wealth of product-related information, often articulated in the form of online consumer reviews. These online consumer reviews are assumed to be more influential than marketer-generated information in determining consumers’ product and brand attitudes (Park, Lee, and Han, 2007). The persuasive impact of consumer reviews, as well as other forms of (electronic) word of mouth, is often attributed to the perceived noncommercial nature of the senders. Consumers are

believed to have no vested interest in recommending a product or brand, and their implied independence renders reviews to be more credible, and consequently, more useful than marketer-generated information (*see* BRAND COMMUNITY; ADVERTISING AND THE INTEGRATED MARKETING COMMUNICATIONS (IMC) PROCESS; SOCIAL NETWORKS; SOCIAL INFLUENCE).

Digital media not only increases consumers’ control over brand communication but they also give advertisers many new possibilities. First, advertisers can (content) analyze the consumer-generated brand information and use it for targeting, customization, and product development. Second, advertisers can use consumer databases to personalize their messages by means of identifying the recipient (by name) and by matching the content of the message to known characteristics and interests of the recipient. Third, they can capitalize on the trend of consumers to actively process brand information by viral marketing (i.e., brand information that is passed along from person to person).

Traditional media. New developments in media can be found not only in digital media but also in traditional media. For example, newspapers have transformed and do look more like magazines with special interest sections, full color print, and lifestyle topics. Out-of-home media are now capable of interacting with the person in front of the billboard by using audio and movements.

The widespread penetration of DVRs and PVRs has resulted in a substantial reduction of live TV viewing time. Instead, a lot of viewing now is recorded viewing time which causes a problem for advertisers because of the risk that ads during recorded programs are skipped. On the other hand, TV offers new advertising possibilities including split screen advertising, EPG (Electronic Program Guide) advertising, and interactive ads. Television is becoming an advertising targeted, participatory, on-demand, nonlinear, two-way communication platform.

Other developments in traditional media have led to a blurring of the differences between media types. This process is called *media convergence*,

which makes it possible to receive the same content on different platforms. TV, for example, can not only be received on a television but also on a mobile phone and via the Internet, and is more selective due to cable and satellite offerings.

Other developments cause a transformation of the traditional media as well. Traditional lines between advertising and editorial content have blurred by presenting brand information in editorial articles and features. This integration of persuasive messages into originally nonsponsored content can be found in a variety of traditional and new media and is known under different names, such as product placement, brand placement, product integrations, advertorials, advergames, and sponsored media content (see PRODUCT PLACEMENT). Advertisers assume that entertainment contributes to attention for their messages. Moreover, sponsored media are more persuasive because audiences may not recognize its persuasive intent as a result of which cognitive defenses against persuasion, which are often automatically raised when encountering advertising, may not be activated. The worldwide increase of sponsoring of sport and music events is a related trend based on the same premises.

With respect to intertwining of advertising and entertainment, several theories in different disciplines (e.g., communication science, media psychology, health education) gradually begin to acknowledge that entertainment is processed in a unique way that differs from processing other communication forms. This unique processing, which has been named experiential, implicit, or heuristic processing in different fields, differs from other, more rational communication processing forms in that it is primary pleasure-oriented and characterized by a primacy of emotional reactions. These processes call for implicit measures of advertising effects, next to the traditional explicit measures.

CONCLUSION

To finalize, this article shows that traditional mass media such as television, radio, newspapers, magazines, and out-of-home are still very

important advertising media, and that classical concepts such as reach, frequency, timing, and costs are still the central metrics for advertising buying and selling. However, new developments in advertising media are becoming increasingly significant and transform the media landscape. These developments can be characterized as more multimedia, targeted, customized, and personalized as well as integrating advertising and transaction. In today's media landscape, advertisers and consumers increasingly change roles in the communication process which places consumers more often in the driving seat.

the role of signage in marketing: outdoor advertising, out-of-home media, and on-premise signs

Charles R. Taylor

RECENT DEVELOPMENTS IN OUTDOOR ADVERTISING AND OUT-OF-HOME MEDIA

In contrast to on-premise signage, outdoor advertising has long been recognized as a traditional advertising medium. Although understudied, more attention has been paid to outdoor advertising. Outdoor advertising has not traditionally accounted for a large proportion of advertising budgets. However, overall expenditures have grown considerably in recent years, with annual expenditures in the United States alone having exceeded \$5 billion in 2000 and every year since then (Outdoor Advertising Association of America, 2008).

In recent years, various types of out-of-home media, such as transit advertising (e.g., on trains and subways), kiosks, street furniture, bus shelters, advertising in airports, malls, health clubs, and other retail establishments, and others have also grown considerably. According to the Outdoor Advertising Association of America, out-of-home media, while accounting for just 2% of overall advertising expenditures, have been growing at a rapid pace (c.f. Wilson and Till, 2008).

As outlined by Taylor (1997), recent years have seen a shift toward a higher proportion of outdoor ads being for retail and service businesses. While there are still important uses of outdoor advertising for manufacturers, this trend makes sense given the primary advantages of outdoor advertising and is verified by the fact that all eight of the top outdoor advertising categories are retail and service businesses, including categories such as local services and amusements, hotels, retailers, media companies, restaurants, auto dealers, and financial services.

Studies by Lilley and DeFranco in 1995 verified that billboard users were predominately locally run businesses. A study of small towns found that 90% of billboard advertisers were locally owned (Lilley and DeFranco, 1995a) and that a large majority were small and medium sized businesses. A similar study of large cities

such as Charlotte in North Carolina, and Indianapolis in Indiana found that 75% of those advertising on billboards were locally owned businesses (Lilley and DeFranco, 1995b).

There is considerable evidence that billboards and other out-of-home media provide unique advantages over other media to the types of firms who use the medium. Taylor and Franke (2003) surveyed billboard users and found that these users did not see other individual media as substitutes for billboards. Billboards were rated higher by their users compared to other media in terms of ability to (i) communicate information affordably, (ii) attract new customers, and (iii) increase sales (*see* ADVERTISING MESSAGE APPEALS). Moreover, most billboard users (75%) reported that they would lose sales if they did not have access to billboards, and the average estimated loss of sales among these users was 18.4%, and 14.2% for the overall sample.

As is well documented in marketing and advertising textbooks, billboards have several unique advantages relative to other advertising media. Textbook authors and academic researchers have identified a variety of distinctive characteristics of billboards and outdoor advertising (e.g., Belch and Belch, 1994; Kelley and Jugenheimer, 2004; Sissors and Baron, 2002; Taylor, 1997; Vanden Bergh and Katz, 1999). The advantages of billboards include (i) potential placement of the advertisement close to the point of sale, (ii) high frequency of exposure to regular commuters, (iii) high reach, (iv) 24-hour presence, (v) geographic flexibility for local advertisers, (vi) economic efficiency in terms of low production costs and low cost per thousand exposures, (vii) visual impact from advertisement size and message creativity, and (viii) brand awareness, among others. The disadvantages of billboards include (i) the need to limit the number of words in the message, (ii) short exposure to the advertisement, (iii) low demographic selectivity, and (iv) measurement problems. Drawing on prior discussion of the medium's advantages, Taylor, Franke, and Bang (2006) surveyed billboard users pertaining to the key reasons they continue to use billboards. A factor analysis revealed four key underlying dimensions that users associated with billboards:

2 the role of signage in marketing

1. *Visibility*: this factor pertains to billboards being easily seen, making a powerful impression, and being visible 24-hours a day.
2. *Media efficiency*: this pertains to billboards having high reach and frequency as well as being cost effective on a cost per thousand exposures basis.
3. *Local presence*: this reflects the ability of billboards to generate awareness/interest in close proximity to the location of a business, to help maintain a brand presence in a local market, and to provide a “last” close to the time of purchase decision.
4. *Tangible response*: the users reported that billboards are effective at generating traffic and helping to drive sales.
2. *Location of the billboard*: it must be located at a good site.
3. *Readability*: the typeface should be legible, there should be a clear contrast, and strong colors should be used.
4. *Clarity*: the message should be communicated efficiently, there should be a simple background, and there should not be more than seven or eight words of text.
5. *Integrated marketing communications*: the billboard should reinforce what is communicated in other customer contacts.
6. *Visuals*: powerful visuals and effective illustrations have a positive impact.
7. *Creative*: clever slogans and novel copy increase effectiveness.
8. *Information*: the message should indicate benefits and uniqueness of product or service.

What is surprising, or at least interesting, about the advantages of billboards is how uniquely suited they are to certain retail and service business, and especially to many smaller businesses, who cannot afford other media. Taylor, Franke, and Bang (2006) theorized that traditional advantages of billboards had been heightened by outdoor advertising's ability to eliminate issues associated with selective perception and geographic advantages consistent with gravity models. In essence, they observed that billboards are simultaneously effective at cutting through an increasingly cluttered advertising environment and capitalizing on the localized nature of the medium. In essence, and consistent with Ephron's (1997) concept of recency planning, outdoor ads often appear in the right geographical location (see PRODUCT PLACEMENT) (close to the business) and at the right time (when the consumer is in a position to make a purchase decision). In this way, outdoor ads often provide a very unique advantage to certain retail and service businesses.

Taylor, Franke, and Bang (2006) also examined creative and executional factors associated with a successful billboard campaign. On the basis of a survey of managers, the following key factors were found:

1. *Name identification*: the billboard must be designed so that the name registers quickly and therefore the name is featured prominently.

Recently, digital technology has added a new dimension to billboards. A typical digital billboard using LCD technology and rotating four to eight ads per minute can generate more revenue for the billboard company than a traditional billboard. Moreover, these billboards bring back access to prime locations to some advertisers who have not had access to them.

While there is debate in some municipalities as to whether, and to what extent, to allow digital billboards, public opinion polls conducted recently by Arbitron indicate that the general public sees significant advantages of billboards. A 2008 study of Cleveland consumers documents that digital billboards are very prone to be noticed and that a large majority of the public thought these billboards help communities communicate emergency information (Arbitron, 2008). The study also found that most of the Cleveland area residents surveyed thought that digital billboards are attractive, are a “cool way to advertise”, and have “current and relevant information.” A 2009 study of Los Angeles consumers by Arbitron (2009) affirmed that very similar results hold. Again, most consumers thought billboards help to communicate emergency information, are a “cool way to advertise,” and have “current and relevant information.” A majority of consumers also believed that digital billboards are attractive.

ON-PREMISE SIGNS AND THEIR USE AS PROMOTIONAL DEVICES

An on-premise sign can be defined as (Taylor, Claus, and Claus, 2005, p. 1.6) follows: “A sign whose message and design relates to a business, profession, product, service, event, or other commercial activity sold, offered, or conducted on the same property where the sign is located. The structure and fact are designed (see PRODUCT DESIGN) in unison and are both integral parts of the sign’s message. These signs may be owned or leased.”

The service sector of the US economy accounts for about 80% of jobs (Winer, 2004). Considering their importance to most retail and service businesses, there has been very little study of the marketing functions of on-premise signs. However, a framework developed by Taylor, Claus, and Claus (2005) provides some insight into the primary functions of on-premise signs. In particular, on-premise signs can play at least four significant roles in marketing and advertising programs. These include

- communicating the location of the business;
- reinforcing advertisements and other marketing variables as part of integrated marketing communications;
- branding the site;
- enhancing store image.

Communicating the location of the business. As a result of performing these functions, on-premise signs contribute to the performance and sales of many businesses in terms of both traffic generation and other less tangible ways. For many retail and service businesses, a fundamental role played by the sign is communicating the location of the business to customers. An on-premise sign often allows the potential customer to learn where the business is located. Thus, the on-premise sign plays a key role for the business by “getting the word out” to the consumer that the business exists at a given location. For certain types of businesses, such as those that rely on impulse purchases, or serve immediate needs, the sign may often induce an immediate response that leads to a sale.

Signs are also important way finding devices. For consumers passing by the business, high visibility of the sign is needed to help the consumer

identify where the store is (Berman and Evans 2007). Thus, on-premise signs help consumers find stores and help businesses by generating traffic.

Reinforcing advertisements and other marketing variables as part of integrated marketing communications. Clearly, on-premise signs function as part of integrated marketing communications. Marketing communications must now be viewed holistically (e.g., Schultz, Tannenbaum, and Lauterborn, 1995), and the idea of integrated marketing communications emphasizes that every point of contact a company has with the consumer must be coordinated in order to maximize the positive impact on the brand (Duncan, 2005). The way in which consumers perceive the brand will result from the synthesis of messages they receive at contact points with the business (Belch and Belch, 2004). Clearly, on-premise signs are an important point of contact that must be viewed as part of a company’s integrated marketing communications strategy. An attractive sign can contribute to positive consumer perceptions of the company. By displaying a logo or brief message, it can also serve to reinforce other messages sent by the marketer, thereby capitalizing on the sign as part of an integrated marketing communications program.

Branding the site. It has been well established that today’s marketers need to think in terms of building brand equity (see PERCEPTION OF BRAND EQUITY) (Keller, 2000). Building brand equity can help a firm increase customer loyalty, decrease price sensitivity, and increase awareness of the company and its brands. (Yoo, Donthu, and Lee, 2000).

For retail and service businesses, the on-premise sign plays a unique and critical role by bringing branding to the site of the business. Trade dress, including trademarks and other aspects of trade dress, can be used both to enhance immediate recall of the business when passing by and to build positive associations with the business in the consumer’s mind. Exposure to trade dress via the on-premise sign can be critical in shaping a business’ image. Additionally, the need to reinforce the brand at the point of purchase for retail and service

4 the role of signage in marketing

businesses is fundamental to maximizing brand equity (Taylor, Claus, and Claus, 2005). For these reasons, we propose that on-premise sign helps businesses to build brand equity with customers.

Enhancing the image of the store or business.

Scholars have long maintained that most brick and mortar retailers must create and reinforce a store image in order to ensure success. Signage can play an important role in communicating the store's image to consumers (Berman and Evans, 2007). The on-premise sign can communicate a high-end image by using expensive signage in conjunction with an elegant storefront. Regardless of the image of the retailer, the on-premise sign should demonstrate consistency with it. It is well documented that retail stores and service businesses need to project a well-defined, distinctive image to consumers in order to be successful.

Collectively, these four marketing and advertising functions of on-premise signs make their effective use important to the promotional programs of retail and service businesses. With the increasing use of digital technology and light emitting diodes (LED) technology, there are now more options for using the on-premise sign to communicate additional information to consumers. Messages promoting the product or services offered can be transmitted digitally, allowing on-site communication with consumers.

Selecting the right on-premise sign for the business. There are several factors that a business should consider in selecting an appropriate on-premise sign in order for it to play the appropriate promotional role for the business (see PRODUCT DESIGN). First, the sign must be of sufficient size for consumers to be able to notice and easily read it. Factoring in that most states allow drivers with 20/40 vision to obtain licensing, a good guideline is that one inch of letter height is needed for every 25 feet of distance from which the business would expect the sign to be readable.

A second factor in choosing the right on-premise sign is ensuring that it is visually conspicuous. In addition to the need to be sufficiently large to be read, an effective sign

needs to stand out from its visual surroundings. When signs are placed in urban environments, they compete with other signs and landscape features in order to be noticed. In order to be conspicuous, the sign must contrast with its background and be easily detectable in the context of the rest of the visual environment.

The height and placement of the sign are also important in allowing it to perform its communications functions. The appropriate height must factor in the speed at which traffic travels and the speed limit. On a four lane highway with a 55 mile per hour speed limit, for example, a sign should be 55 feet high (for more information, see Taylor, Claus, and Claus, 2005 on page 8.5). Placement refers to making sure the sign is placed at a location that will allow a motorist to respond in time upon seeing the sign. This factor should be considered in site selection.

For businesses that operate at night or wish to promote themselves at night, proper illumination of the sign is a fifth important factor to consider in obtaining an on-premise sign. Lighting very much impacts the effectiveness of the sign.

Perhaps most important from a promotional standpoint is the need for the sign to communicate something about the business. An effective sign will communicate something to people about what they will find on the inside of the business. Here, the design, color, and content of the sign must be carefully considered. Logos and trade dress can often be used effectively, and other messages about the business can sometimes be communicated either through lettering or, more recently, through new technologies.

SUMMARY AND CONCLUSION

Outdoor advertising and the marketing functions of on-premise signs have been understudied topics for many years. However, given their importance to business and a more cluttered advertising and promotional environment, it is likely that more attention will be paid to signage by academics, going forward. Research has documented that outdoor advertising is important to the very viability of many businesses, most of which are small or medium-sized local businesses. Meanwhile, larger national advertisers can use out-of-home media effectively as part of

an overall integrated marketing communications strategy.

On-premise signs have long been very important to businesses but have been the subject of very few academic studies in spite of the role they play for many businesses. Like billboards, they can be especially important to small and medium-sized businesses in terms of their viability. Going forward, more research on the marketing roles of on-premise signs is needed.

trade promotions: issues and findings

Naveen Donthu and Amit Poddar

Trade promotions are any promotions that are targeted toward the trade (supply chain). They come in many forms, such as cash discounts, off-invoice, scan backs, quantity discounts, and so forth. They are generally classified as push promotions as the goal of the promotion is to induce the trade to push the promoted product. According to some estimates, trade promotions overall command 52% of the total money spent on advertising and promotion (1999), whereas the rest of the money is shared between advertising and consumer promotions.

Our goal in this article is to bring together important findings in the trade promotion literature and summarize what we know about trade promotions. We have classified the findings into eight substantive questions.

1. Why do firms offer trade promotions?
2. What is the value of trade promotions?
3. What are the factors that lead to trade promotion success?
4. Can trade promotions be explained as power games?
5. What are the costs and inefficiencies of trade promotions?
6. Can trade promotions be improved?
7. What are the main problems with trade promotions?
8. Are slotting fees good for firms?

WHY DO FIRMS OFFER TRADE PROMOTIONS?

Researchers and practitioners know that trade promotions do not build long-term consumer franchise. They also know that retailers often do not pass on trade deals to consumers. Then the question is why firms offer trade deals to retailers instead of just sticking with consumer promotions or advertising? Existing research offers three basic theories to explain why firms offer trade promotions: inventory holding cost theory, weak customer equity theory, and colluding marketer theory.

Inventory holding cost theory. Trade promotion logic describes that retailers who receive

the promotion pass on some of the money to consumers as price promotions, which encourages trial. This seems to be a reasonable explanation for new-product introductions, but this does not explain why trade promotions take place in mature markets. It can be argued that retailers use price promotions to shift inventory holding costs to the consumers, because consumers have lower holding costs. Cui, Raju, and Zhang (2008) argue that big retailers may also have lower holding costs compared to manufacturers (or vendors), in which case it makes sense for the manufacturer to shift some of its own holding costs to the retailer through trade deals. The effect of this inventory holding cost transfer benefits both the retailer and the vendor, and the inventory cost differential allows vendors to price discriminate using trade promotions.

Weak customer equity theory. Although the inventory cost theory makes intuitive sense, trade deals also might result from the customer equity of the firms. According to Raju, Srinivasan, and Lal (1990), in a competitive market with different levels of brand equity, strong brands know they can lure a weaker brand's customers away with price discounts. To defend its turf, the weaker brand uses promotions to keep its customers, and the result is that all brands promote. This line of research also indicates that weaker brands tend to gain more from temporary price discounts. However, if all competing brands have high brand loyalty, pure equilibrium exists, and no one promotes. Therefore, trade promotions are inevitable whenever there are weaker brands in the market.

Colluding marketer theory. Another interesting explanation of trade discounts comes from Lal (1990), who suggests that many brands promote as a form of implicit collusion to prevent encroachment by private brands. In a study of the beverage market, Lal finds that national brands (e.g., Coca-Cola, Pepsi) fight competition from local brands by reducing their prices in alternate periods in an infinite horizon game.

WHAT IS THE VALUE OF TRADE PROMOTIONS?

It is well accepted that trade promotions lead to increased sales in the short run. Researchers

2 trade promotions: issues and findings

and practitioners often wonder if increased sales translate into increased value captured by the firm in the form of incremental revenue minus the cost of the promotion.

When manufacturers provide a trade deal, they incur a cost, equal to the income transferred from them to the retailers. However, this income transfer is mitigated by the increased sales of their products. As long as the increased sales are greater than the increased costs, the process benefits the manufacturer, and the value is positive. The manufacturer faces two caveats though: It must know its baseline sales before it can claim an increase in sales, and the trade promotions should not just prompt sales that the manufacturer would have made anyway in the future.

The impact on retailers' profits is more complicated. Retailers benefit from trade promotions in many ways. First, they might buy at discounted prices and sell at normal prices. Second, trade promotions might allow them to sell more of the promoted product when they pass on the savings. These increased sales lead to higher inventory turnover. The discounted price may also allow the retailer to claim price leadership, which can lead to more sales in different product categories. However, retailers also incur costs that are difficult to capture, such as the costs attached to forward buying, in that buying more than required increases inventory holdings, which reduces profits. When retailers promote some products, they also might suffer reduced sales of nonpromoted products, which could have higher margins. Finally, the reduction in sales of other products could lead to higher inventory costs for the nonpromoted products, which adds to the retailers' losses. Existing research has only been partially successful in calculating the actual worth of trade deals. The jury is still out regarding the impact of trade deals on profitability.

Value of trade deals for the manufacturer.

Researchers have long speculated that trade promotions may be value losers, causing them to investigate both the long- and short-term impacts of trade promotions. Manufacturers blame retailers for taking advantage of trade promotions but not passing on the benefits to the ultimate consumers. It is estimated that approximately 30% of the money spent on trade

promotions goes straight to the bottom line of the retailers (Kasulis *et al.*, 1999). Blattberg and Levin (1987) attempt to model how retailers might behave when offered trade promotions and which promotions would be best for them. They note that if promotions do not increase consumer sales, they merely shift the timing of the retailer's purchase. Empirically, they find that trade promotions do not pay for manufacturers. Overall, researchers seem to agree that trade deals look like a losing proposition for manufacturers.

Value of trade deals for the retailer. The impact of trade promotions on retailer profit may not be clear because of various factors such as forward buying, reduced profitability of promoted items, reduced sales of nonpromoted items because of consumers buying promoted items, and the possibility that consumers drawn to stores could end up buying other products that actually increase overall sales.

Trade promotions may favor retailers that forward buy but not manufacturers when the retailer's promotions reduce the brand value. Similarly, promotions may be favorable to manufacturers and unfavorable to retailers when increased price cutting occurs at the retailer level to prevent undercutting by competitors. If all the costs of trade promotions, including advertising, display setup, and display rent, are charged to the promotions, their value might become negative.

Recent research indicates a negative net profit impact of trade promotions. Ailawadi *et al.* (2006) find that trade promotions provide an incremental sales lift of 45%, but the profit impact is negative because the products that create higher promotional bumps earn lower margins overall. This problem gets aggravated when all promoted products earn the lower margin, not only the incremental units. They also find that despite sales increases, more than half the promotions are not profitable for the retailer.

WHAT ARE THE FACTORS THAT LEAD TO TRADE PROMOTION SUCCESS?

Because not all trade promotions succeed in creating value, researchers have attempted to

pinpoint the factors required for a successful promotion. Overall, managers realize that considering the amount of money at stake, it makes sense to develop a trade promotion that works.

Management-based success criteria. Hardy (1986) contends that to determine success, the objectives of the promotion have to be specified first. He lists the following main objectives of trade promotions:

1. Achieve short-term volume.
2. Achieve long-term market share.
3. Build trade inventories.
4. Increase consumer trials.

He also proposes that these objectives are dependent on the promotion period, promotion cost, trade support, presence of competitive promotions, level of incentives, and presence of consumer promotions alongside trade promotions. His empirical tests reveal that achieving trade support is the most critical factor for achieving the objectives of the firm. Hardy (1986) also finds that in the view of managers, trade promotions succeed only when high incentives, good trade support, good sales force support, and an absence of competitive activity exist. The reasons for unsuccessful trade promotions include buildup inventory from previous deals, insufficient incentives, competitive promotions, and a lack of trade support.

Deal-based success criteria. Walters's (1989) empirical investigation attempts to determine the level of retailer trade support, thus delving deeper into Hardy's (1986) assertion that trade support represents the most critical success factor in trade promotions. Walters uncovers empirical evidence that suggests that economic incentives contained in deals, such as advertising support, price reductions, and product displays, significantly affect retailers' support of trade deals. He also finds that the time since the last promotion in the same category influences retailer support, though he does not find any significant impact of product-related factors (e.g., store sales rank of product category and product sales rank in category), manufacturer's consumer promotions, or the price elasticity

trade promotions: issues and findings 3

of the product on trade support. The finding that consumer promotions have no impact on trade support seems surprising, because conventional wisdom indicates retailers should be more willing to provide trade support when trade deals accompany consumer promotions. It also contradicts Hardy's (1986) findings that consumer promotions, run simultaneously with trade promotions, affect the success of trade promotions.

CAN TRADE PROMOTIONS BE EXPLAINED AS A POWER GAME?

Power plays an important role in the relationship between the retailer and the vendor. Because trade promotions entail income transfers, power plays an important role in determining the extent and the form of transfer. Understanding the power conundrum and its role remains an important research problem, for which researchers use game theory to predict why trade promotions take place and explain the different kinds of trade deals that may appear in different power asymmetry situations.

Game theoretic explanation of trade promotions.

Researchers have tried to study trade promotions as a sort of prisoner's dilemma, which would imply one best strategy for a firm, irrespective of what its competitor does. Rao, Arjunji, and Murthi (1995) model trade promotions as a series of competitive games and hypothesize about the actions of the parties, depending on a series of promotion outcomes. For example, they predict that if a promotion is profitable, regardless of what the competition does, it represents a prisoner's dilemma game, and both parties end up promoting. However, if the promotion is profitable only if the competitor does not promote, the game type is a "battle of sexes," and it is not possible to go without promotions over a long period of time. They demonstrate empirically that promotion activity seems independent of competitor actions; that is, competitors do not necessarily choose their promotion actions after they take into account the actions of their competitors.

Power asymmetry and impact on different forms of trade deals. Kasulis *et al.* (1999) also address trade promotions as the result of a power game

4 trade promotions: issues and findings

between the manufacturer and the retailer. Considering the relative power between the two parties, they hypothesize that the use of different forms of trade promotions has different objectives. Their conceptual framework consists of a two by two matrix (high versus low) of retailer and manufacturer power, such that when the retailer dominates, they anticipate promotions that shift channel profits from the manufacturer to the retailer (e.g., bill backs, slotting fees, and inventory financing). When the manufacturer is more powerful than retailers, it sees little point in offering trade deals and instead focuses on consumer promotions that increase customer loyalty. In the symmetric case when both the retailer and the supplier are strong, Kasulis and colleagues propose a higher incidence of promotions such as co-op advertising, display advertising, and calendar marketing agreements, whereas in a weakly symmetric case, both parties enter survival mode and likely use promotions that result in temporary price cuts passed on to consumers.

G'omez, Maratou, and Just (2006) find that as the power of the manufacturer increases, the amount of funds allocated to trade deals declines, whereas greater retailer bargaining power leads to more focus on deals such as off-invoice agreements. Retail companies with larger shares of private labels and greater annual sales can increase the allocation of promotional funds toward off-invoice agreements and away from performance-based trade promotions, such as scan backs and bill backs (G'omez, Rao, and McLaughlin, 2007). Although manufacturers may have greater autonomy in determining trade promotion budgets, retailers have a greater say in the allocation of the funds. The authors find only mild support for the notion that the retailer and vendor decide on the overall budget and allocation pattern in a joint negotiation process. Similarly Ailawadi and Harlam (2009), considering the role of power with respect to retail pass-through, note that higher manufacturer power increases pass-through, but higher retail power is associated with lower pass-through.

WHAT ARE THE COSTS AND INEFFICIENCIES OF TRADE PROMOTIONS?

Researchers worry that trade promotions might add costs that get passed on to the ultimate consumer. Researchers thus have tried to calculate the cost that is added to products due to trade promotion.

Calculating the dollar cost of trade deals. Buzzell, Quelch, and Salmon (1990) calculate that trade promotions add 0.5–1.1% to total retail prices. To calculate these costs, they note that trade promotions (especially price promotions) have distinct impacts on retailer behavior. Trade promotions lead to the phenomenon of forward buying, such that retailers take advantage of the lower prices to forward buy for later sales at normal prices. Retailers have a motivation to forward buy until the savings from the lower prices equal their holding costs. They calculate the holding costs to be approximately 30%, which include handling, storage, and capital charges. Their article also highlights two main negative effects of trade promotions: (i) they lead to distrust between the manufacturer and distributor, which could prompt higher transaction costs; and (ii) forward buying leads to wasteful storage and diversion expenses that help no one in particular.

The cost burden of trade promotions is not borne by everyone in equal measure. People classified as “cherry pickers” (bargain hunters) get a lower price, whereas normal, brand-loyal consumers end up paying higher prices. Therefore, loyal consumers subsidize nonloyal consumers, which is bad for the manufacturer in the long run.

Dangers of going without trade deals. Prior to 1995, research held that forward buying adds inefficiency to the channel system, ensuring that the manufacturer is always worse off. Trade deals thus had to be unprofitable, because the retailers would forward buy and keep the promotion to themselves. Lal, Little, and Villas-Boas (1996) challenge this deeply held belief by modeling the behavior of manufacturers, retailers, and consumers. They find that in equilibrium, manufacturers benefit when they allow forward buying compared with when they do not. The intuition behind

their surprising result states that allowing retailers to forward buy reduces the intensity of competition (between manufacturers), which helps the manufacturer. Moreover, forward buying decreases income for the manufacturer, but manufacturers still achieve a better position than they could have with the prices that would have resulted without forward buying and with a higher intensity of competition. Lal, Little, and Villas-Boas (1996), however, acknowledge that forward buying has a negative impact on total channel costs. It creates serious logistical dysfunctions, leading to the excess storage of inventory, which creates inventory storage costs.

CAN TRADE PROMOTIONS BE IMPROVED?

Considering that the current way of doing trade promotions creates inefficiencies in the supply chain, researchers have made considerable efforts to suggest ways in which trade promotion inefficiencies might be removed. Some of the most common suggestions include every day low purchase price (EDLPP), scan backs, and electronic forward buys. Suggestions have also been made to improve the retail pass-through, which is likely to improve the long-term benefits of trade promotions.

Evaluation of everyday low purchase price method. Buzzell, Quelch, and Salmon (1990) may have been the first researchers to suggest a policy for EDLPP to reduce the costs of running trade promotions. They argue that the retailer should purchase on an as-needed basis and receive a weighted average price that reflects both the deal price and the promoted price. There are three benefits of EDLPP. First, it prevents inventory buildup for both manufacturers and retailers; second, it reduces selling and administration expenses because retailers would spend less time negotiating trade deals; and third, it leads to a more collaborative relationship between the retailer and the manufacturer, in which both are freed from the zero sum game in which one party wins only at the expense of the other. They also posit that following an EDLPP approach leads to more pass-through, which lowers the prices for consumers.

Neslin, Powell, and Stones (1995) also mention decreasing pass-through, greater

promotion intensity, and increased retailer warehousing ability (which allows for forward buying) as reasons for an EDLPP strategy by manufacturers. However, they warn that consumer factors may prevent a wholesale move to EDLPP. Consumer responses to deals remain intact, and media advertising appears to be losing effectiveness, which have opposing effects on the adoption of EDLPP. Further speculation indicates that promotional elasticities might far exceed price elasticities, in which case the EDLPP strategy becomes questionable. Mangers may prefer to keep a higher shelf price and then offer discounts to generate more sales and profits.

Although several authors praise EDLPP as a solution to deal-to-deal forward buying, Ailawadi, Farris, and Shames (1999) claim that it may be strong medicine that causes its own side effects. They decry the tendency by manufacturers to blame trade promotions, stating that in the absence of trade promotions, manufacturers would have to charge much less than their current list prices, in agreement with Lal, Little, and Villas-Boas (1996). They adopt a different view of how to improve trade promotions; the main problem with trade discounts, as they see it, is that they are linked to the quantity bought, which encourages forward buying and creates problems with pass-through. They instead suggest that the goal of the manufacturer should be to design trade promotions to increase total channel profit. With their analytical model they demonstrate that linking promotional allowances to the list price charged by the retailer increases total channel profit. The intuition behind their thinking is that if the retailer receives encouragement to charge a lower price (because the total allowance depends on the price charged to the consumer), total base demand increases, which should help both the retailer and the manufacturer.

Improving and increasing retail pass-through.

Another problem that plagues the effective implementation of trade promotion is retail pass-through, which occurs in response to "retailer opportunism." Kumar, Rajiv, and Jeuland (2001) state that the manufacturer wants the retailer to pass on the trade promotion money to the consumer as reduced prices, but

6 trade promotions: issues and findings

the retailer does not because of its information asymmetry. The consumer has no way of knowing when the manufacturer has provided a trade promotion. If the retailer never passes on a trade promotion, the consumer might become suspicious and shop elsewhere, so the retailer occasionally charges a lower price in association with a trade promotion but charges a normal price on other occasions. They suggest and demonstrate that when manufacturers advertise their ongoing trade promotions directly to consumers, it increases retail pass-through and thus reduces retailer opportunism.

Few empirical articles review actual retail pass-through, though a recent study (Ailawadi and Harlam, 2009) suggests that retail pass-throughs for individual manufacturers reach approximately 75% and that retailers actually spend more than 100% of the funds they receive as trade promotions. However, the retailers shift their trade promotion dollars from individual vendors to private labels and categories with higher sales and higher market share. Thus, retailers appear to view trade promotions as a pool of money they can spend in whatever way provides them with the greatest benefit.

Evaluating performance-based trade deals – the scan back. The call to eliminate forward buying has led to the creation and advocacy of a new type of trade promotion, the “scan back,” which has become increasingly popular among manufacturers. With a scan back, the retailer receives promotion money only when it sells the product to the final consumer (tracked by scanner data during the promotion period), not when it buys the product. This approach effectively prevents any forward buying, because if the retailer buys extra inventory that it cannot sell during the promotion period, it loses promotion money. Recommendations of the scan back scheme promote it as a panacea for trade promotion ills. However, Dreze and Bell (2003), using an analytical model, prove that when the terms of the trade are identical (i.e., base size, deal size, and deal duration), manufacturers always prefer scan backs and retailers always prefer off-invoice deals. Because scan backs have benefits, in terms of reducing forward buying (which adds cost to the overall channel system), they suggest that the

only way manufacturers can convince retailers to adopt scan backs is to compensate them for the loss of profit opportunities. To prove that such a system is possible, Dreze and Bell devise a modified scan back (which they call a mimic scan back) that leaves the retailer weakly better off and the manufacturer strictly better off – a sort of win-win solution for both parties. They propose that to create a mimic scan back, the manufacturer must provide a smaller deal for a longer period of time and lower the base price of the product. They also find empirical evidence that scan backs lead to more retail pass-throughs and lower retail prices, which in turn result in greater sales.

Most of the research which suggests ways to improve trade promotion efficiency considers the problem only from the manufacturer perspective. Suggestions, such as scan backs, are very beneficial from the point of view of the manufacturer but would never work unless retailers are also benefited from them. Similarly, though EDLPP might look very attractive for the manufacturer, it is not very attractive to the retailer. The failure of these alternate systems to catch on suggests that retailers are not buying into systems that fail to demonstrate obvious benefits for them.

IDENTIFYING PROBLEMS WITH TRADE PROMOTIONS

Managers and academics have long believed that trade promotions create more problems than they solve. They specifically are thought to have a strong effect on cooperation between business partners. The key finding is that because trade promotions are looked at as zero sum games, retailers and vendors end up competing with each other rather than cooperating.

Effect on competition and consumer behavior.

Trade promotions create adversarial relationships between partners and also create competitive retaliation between competitors. The effect on the brand being promoted is also substantial. Trade deals end up stealing funds from advertising, which devalue the brand image/consumer franchise in the long run. Trade deals can have negative effects on the performance of manufacturer in the short and long run. First, trade deals

can increase the price of products in the marketplace, leading to reduced demand. Second, the increasing market price may prompt the retailer to enter the market with its own private brands, in which case the manufacturer has created its own competitors. Third, as a result of high inter-retailer competition, retailers may become more aggressive in demanding trade deals, which reduces trust between the retailer and the manufacturer. Fourth, high fluctuations in the market price may cause consumers to become more price conscious and turn them into constant deal seekers. Fifth, as manufacturers dedicate more and more money to trade promotions, their ability to create brand differentiation decreases over time. This development has a long-term impact on the ability to charge consumers a premium for the brand.

ARE SLOTTING FEES GOOD FOR FIRMS?

No discussion about trade promotions would be complete without mentioning the current controversy about the appropriateness of slotting fees. Retailers and wholesalers frequently require manufacturers to pay some sort of fees before they agree to stock a new product. Although a form of trade promotion, the impact of these slotting fees does not apply to mature products. According to Sudhir and Rao (2006), slotting fees vary from \$1.4 to 2 million for a national-level introduction of a single SKU. The ongoing controversy about slotting fees persists because researchers cannot agree about the role they play in manufacturer–retailer relationships. There are two main schools of thought with diametrically opposing views, namely, the efficiency effects and the market power effects of slotting fees.

Efficiency effects of slotting fees. The first school of thought, the “efficiency school,” states that slotting fees actually increase efficiency in the system by

1. providing a signaling mechanism for manufacturers to advertise product quality.
2. sharing risks between the retailer and the manufacturer. Because of information asymmetry, the retailer likely knows less than the manufacturer about the probability of success of the product. Therefore, it

suffers a disproportionate amount of risk for a product introduction. Slotting fees help maintain the balance by shifting the risk from the retailer to the manufacturer.

3. aiding in the efficient allocation of shelf space. Slotting allowances help the retailer make efficient use of its scarce shelf space. In effect slotting allowances help totally new products attain shelf space, whereas normally, they would have been rejected because they were untested in terms of marketplace performance.
4. increasing competition and thus reducing total retail prices.

The efficiency school of thought largely is favored by retailers that want slotting fees to continue.

Market power effects of slotting fees. The other school of thought, called “market power,” argues that slotting fees actually are harmful and damage competition and overall consumer behavior by

1. allowing retailers to use their market power to demand and obtain fees. Retailers thus can demand more fees from smaller manufacturers.
2. undermining channel relationships, because manufacturers become bitter about being made to pay fees to get their products to the market.
3. providing a mechanism for price discrimination. When different manufacturers pay differential fees, the costs increase disproportionately.
4. introducing unfair competition for certain manufacturers that cannot pay the slotting fees and thus just quit the market. This is especially true for small startups who often cannot afford the fees to get on the shelves.
5. harming the consumer, because the fees ultimately are passed on to consumers in the form of higher list prices.

Bloom, Gundlach, and Cannon (2000) use a survey methodology to discover that retailers and manufacturers do not agree about slotting fees constituting a signaling mechanism, though they concur that the fees shift risk from the retailer to the manufacturer. Furthermore, both

8 trade promotions: issues and findings

retailers and vendors agree that slotting fees benefit large manufacturers and lead to higher prices. Overall, their research supports the power school of thought, though a recent article by Sudhir and Rao (2006) challenges their findings and suggests that the efficiency theories actually are right.

CONCLUSION

The industry already spends more on trade promotions than on any other marketing activity, yet we also know the least about it, which means that there is a significant opportunity for understanding and obtaining efficiency gains. Since the gains from trade promotion directly affect the expense side of profit-and-loss statements, companies could realize massive benefits from any improvements to trade promotions.

business-to-business media selection

Kyle Krueger and Lawrence Soley

Advertising media selection for business-to-business (B2B) marketers is a process similar to that used with consumer advertising (see ADVERTISING MEDIA SELECTION). A media planner working for a B2B advertiser is concerned with selecting the proper media (e.g., trade publications) and vehicles (e.g., *Builder Magazine*) to reach the target market (e.g., remodeling contractors). The selection method consists of making qualitative decisions, such as choosing vehicles that provide a suitable editorial setting for the product or service being advertised, and quantitative judgments, such as calculating the vehicle's relative cost efficiency. A B2B media planner looks to efficiently select media that achieve the advertiser's communication objectives, such as building brand awareness, and marketing objectives, such as customer retention and loyalty (see ADVERTISING EFFECTIVENESS).

Historically, the media type preferred by the B2B media planner has been trade publications. Even in the age of Internet advertising, trade publications still account for 13% of B2B media spending. Business executives spend an average of 2 hours per week reading industry-related magazines (Sorce and Dewitz, 2007). Other preferred media channels include direct mail, trade shows, affiliate marketing, and digital media, including email, internet display ads, CDs, and search engine marketing. With trade publications, these media types account for 60% of B2B advertising expenditures (Sorce and Dewitz, 2007). One reason media spending for digital media is higher than for print publications is that most business publications produce online editions, blogs, and forums, and distribute e-newsletters. Many trade publications also lease their subscriber lists for direct mail.

When evaluating the cost efficiency of a trade publication, a media planner will usually use circulation figures, rather than readership, as is done with consumer publications. This is because there are no syndicated services measuring trade publication audiences, as there are for consumer magazines and newspapers. In contrast with business publications, Mediarmk

Research, Inc. (MRI) and Experian's Simmons Market Research Bureau (SMRB) measure the readership of large circulation consumer magazines and Scarborough Research measures the audiences of daily newspapers. Because readership data are usually unavailable for trade publications, cost efficiencies are usually calculated using the following cost-per-thousand formula: $\text{cost-per-thousand} = \frac{\text{advertising rate} \times 1000}{\text{circulation}}$.

The circulations reported by trade publications are authenticated by several auditing services, the largest in the B2B marketing field being the Business Publications Audits of Circulation (BPA). The BPA primarily audits controlled circulation publications, which are funded entirely by advertising and provided at little or no cost to readers, but it also audits business publications that principally have paid circulations (e.g., *Marketing News*). The BPA is a nonprofit, self-regulating organization created by advertisers, publishers, and advertising agencies to assure that the circulation figures provided by business publications are accurate. It audits the circulations of more than 1900 business publications worldwide, including many publications for marketing professionals, such as *Adweek*, *BrandWeek*, and *B to B*, a 15-issue per year magazine for B2B marketing professionals. The audits also assure that direct mailings based on the trade publication's subscriber list also reach the intended targets.

Within trade publications, *Brandweek* and *B to B* are classified as horizontal trade publications. Horizontal trade publications run across industries, and usually have larger circulations than vertical publications. For example, *B to B* is read by marketing professionals in many industries, including the financial services, manufacturing, retail, travel, and publishing industries. Vertical publications are distributed with a single industry. As an example, *Progressive Railroading* is distributed to employees in the railroading industry, including professionals in management, marketing, signaling, purchasing, and even locomotive repair.

The BPA, when auditing trade publication circulations, analyzes and reports the industry and job classifications of subscribers, as well as their geographic locations, which allows

2 business-to-business media selection

media planners to more efficiently compare the cost efficiencies of vertical and horizontal trade publications. The target group is referred to as the magazine's qualified circulation, and cost-per-thousands can be calculated using the qualified circulation. The circulation breakdowns also allow a B2B media planner to compare the cost efficiencies of reaching the qualified subscribers who work in the media (such as at broadcasting stations and newspapers) using a horizontal publication such as *Adweek*, as compared to vertical publications such as *Broadcasting & Cable* and *Editor & Publisher*.

Similar to the BPA, the Audit Bureau of Circulation (ABC), verifies the circulation statements of consumer magazines, newspapers, and some business publications, particularly those with large percentages of paid circulation. Like BPA, the ABC is a nonprofit, industry-sponsored organization. As an example, *Advertising Age*, which has more paid subscribers than nonpaid subscribers, is audited by the ABC. Some media planners tend to devalue nonpaid circulation when compared to paid circulation on the grounds that subscribers who pay to subscribe are probably more likely to read the periodical than those who receive it for free.

The ABC also conducts web audits. To assure that its estimates of web visits are accurate, the ABC requires online publishers to submit their log files to the ABC for analysis. The ABC analyzes the logs, removing visits generated internally, by robots and by duplication. The ABC publishes a "Consolidated Media Report" that combines circulation and web site traffic for trade publications, which can be used by media planners to calculate the relative cost efficiencies of the combined media. The ABC's consolidated report produced some controversy because the "total contacts" figures that it presents includes duplication – individuals who have read the magazine and have also visited the publication's web page, blogs and forums (Schwartz, 2006). Thus the combination does not produce an estimate of the vehicles' reach, but gives only its gross impressions. The BPA also audits visits to over 100 B2B websites. The BPA audit contains monthly data on unique browsers, page impressions, browser frequency, session duration, and page duration (BPA Worldwide, 2009).

The ABC has also started verifying readership studies conducted by trade publishers that use its auditing services. This is an attempt to make data for trade publications comparable to that for consumer magazines and newspapers, which often report readership rather than circulation numbers. The ABC works with the marketing research firm hired by the publisher to conduct its readership study, and assures that the sample selected is representative. The ABC also monitors the response rates and method for projecting the readership of the publication. Although relatively few trade publications measure readership when readership data are available, the cost efficiencies of vehicles can be assessed using the cost-per-thousand formula for comparing consumer magazine and newspapers: $\text{cost-per-thousand} = \text{rate} \times 1000 / \text{readership}$.

A few other companies, including Verified Audit Circulation (VAC), conduct comparable audits for niche trade and regional publications, direct to business marketing, and internet websites. VAC audits the circulations of publications such as *American Drycleaner*, *Idaho Business Review*, *Pit & Quarry*, and *Southern Loggin' Times*.

Media planners use the audit reports to compare one publication's circulation against another's. A publication with a higher qualified circulation may be seen as more valuable to an advertiser than a publication that has a higher unqualified circulation. Additional information gathered by an audit includes how a publication is addressed to its recipients, a geographical breakout of qualified circulation by state and region, and average qualified circulation over the previous 5 years. These data can be used by media planners to estimate whether a magazine's circulation has probably increased or decreased since the last audit.

In summary, a B2B advertiser's communication and marketing objectives can be obtained through the skilled use of tools available to the media planner. Auditing services play a valuable role in helping media planners select the proper vehicles to place advertisements. These services provide an equalized set of data which help media planners compare the merits of publications, digital media, and direct mail.

advertising effectiveness

Jacqueline J. Kacen

INTRODUCTION

In 2001, advertisers paid an average of \$2 million for 30 s of television commercial time during Super Bowl XXXV (O'Connell, 2002). Of seven nationally known brands that bought advertising during the game – Budweiser, Cingular, Dentyne Ice, Doritos, MasterCard, Pepsi-Cola, and Visa – only two saw a gain in market share during the year (O'Connell, 2002). Does advertising work?

ADVERTISING EFFECTIVENESS DEFINED

The goal of advertising is to persuade. *Advertising* is defined as any paid, mediated form of communication from an identifiable source, designed to persuade the receiver to take some action, now or in the future (Richards and Curran, 2002, p. 74). *Advertising effectiveness* is defined as an evaluation of the extent to which a specific advertisement or advertising campaign meets the objectives specified by the client (American Marketing Association, 2009). The effectiveness of advertising depends, of course, on what *specific* objective the advertiser has, and what *specific* action the advertiser is trying to persuade the receiver to take with respect to the advertisement.

At the most basic level, advertising effectiveness can be defined as some form of positive human response to a marketing communication. Human responses to advertising can be separated into two general categories: (i) effects on behavior, that is, sales, and (ii) cognitive and affective effects, that is, awareness, perceptions, and beliefs. Advertising, if successful at stimulating sales or influencing behavior, must first produce effects at the individual cognitive and affective level.

DIFFICULTY MEASURING ADVERTISING EFFECTIVENESS

The effectiveness of advertising is difficult to measure. Establishing a direct link between exposure to mass media advertising (e.g., television commercials, billboards) and subsequent purchase is problematical (exceptions include *direct response advertising*). First, advertising

is only one aspect of the “4Ps” (product, price, place, and promotion) that leads to sales. Consumers may buy a product for a variety of reasons. In fact, for most consumer-packaged goods, price and sales promotions have been shown to have a greater influence on purchase choice than exposure to advertising (Tellis, 2004). Some products achieve sales without advertising, due to word of mouth, news stories, and other nonpaid communications about the brand. Isolating the effect of advertising on sales while controlling for other factors is a difficult task.

Second, advertising has cumulative, lagged, and carryover effects. Repeated exposure to an ad may be necessary before interest in the product is generated. Exposure to an ad may occur long before the purchase takes place. In addition, the longer a brand is known, the more its ads are remembered (Kapferer, 2008). Brands that have been advertising for a long time (e.g., Coca-Cola, Budweiser) are familiar and may require little or no advertising in a given period to achieve sales results. Some of the long-term sales effects of current-period advertising can be attributed to consumers' earlier experiences and familiarity with the product (Givon and Horsky, 1990). Carryover effects in advertising mean that early exposure to an ad can influence later purchase decisions even when no advertising has occurred in that sales period (Tellis, 2004). Advertising makes positive brand evaluations and attitudes readily accessible in memory (Farquhar, 1989). As a result, advertised brands more readily come to mind even when no advertising is present.

Third, competitive activity impacts consumers' responsiveness to advertising. In some cases, advertisements for competitive brands can “prime” consumer interest in the whole category of brands, leading to greater advertising effectiveness. In other cases, competitive advertising can lead to advertising clutter, reduced share of voice, and decreased attention to advertising, reducing its effectiveness.

FINDINGS ON ADVERTISING EFFECTIVENESS

On the basis of an extensive review of 50 years of research studies investigating the elasticity of advertising across various product categories, product life-cycle stages, countries, types of data,

2 advertising effectiveness

and types of statistical models, the evidence suggests that a 10% increase in advertising leads to a 1% increase in sales (Tellis, 2004). This relatively small effect indicates that advertising is not an all-powerful force. As a point of comparison, the elasticity of price to sales is about 15% (Tellis, 2004). Advertising does influence behavior and generates sales, but it is a subtle force that must be carefully planned and executed to be effective.

HOW ADVERTISING WORKS

The majority of advertising is brand-oriented, designed to persuade a target audience to respond favorably toward the advertised product—that is, to cause a change in beliefs, attitudes, and intentions in such a way as to motivate purchase. Traditionally, advertisers have viewed these mental processes in terms of a *hierarchy of effects* (see e.g., McGuire, 1978). The hierarchy-of-effects approach to advertising sees the individual as an information processor who proceeds through a linked chain of steps that begins with exposure to the ad, and is followed by attention to the brand, comprehension and understanding of the brand message, conviction about the brand (attitude change), and finally, purchase (McGuire, 1978). It is the job of advertising therefore, to promote the saliency (awareness) of the brand, to endow it with uniqueness and perceived differences from other brands in the marketplace, and to enhance the brand's reputation in the minds of consumers (Kapferer, 2008). Advertising achieves effectiveness by generating in consumers the mental processes that positively influence their beliefs and associations about the brand, enhance brand desirability, and encourage purchase.

HIERARCHY OF EFFECTS

Awareness. Awareness of the brand is affected by the amount of brand advertising (*advertising weight*) and the placement of the advertising (where and when the ads appear), as well as the total amount of advertising vying for the individual's attention. High levels of advertising increase the likelihood that the brand message will break through the clutter of other advertising messages, and be seen by the target market. Research has demonstrated that companies should advertise heavily when the product is

introduced but can reduce the amount of advertising later in the product's life cycle (Horsky and Simon, 1983). For familiar brands, expanding *reach* (number of people exposed to an advertisement) is generally more effective at stimulating sales than increasing *frequency* (the number of exposures a person has to an advertisement) (Ephron, 1995; Tellis, 2004).

While the level of advertising is important for creating brand awareness, the content of the advertising, the media through which the advertising is communicated, and when the advertising appears are critical to the hierarchy-of-effects process—that is, moving consumers from awareness to purchase. For example, research has shown that advertising is more effective when the brand name appears at the beginning of an ad rather than at the end (Baker and Honea, 2004). Attention to television commercials drops second by second; if the brand name is not mentioned until the end of the commercial, the memory association between the brand name and the message content is weakened, making the advertising less effective (Baker and Honea, 2004; Stewart and Koslow, 1989; Wells, 1997). Overall, advertising content, media channels, and scheduling generally have a greater impact on sales than the amount of advertising.

Persuasion. The main purpose of brand advertising is to persuade the consumer to purchase the brand. The attitude formation/change process differs depending on the consumer's level of involvement with the advertising (Krugman, 1966). Involvement plays a key role in determining how much effort is put into processing an ad message, and what kind of ad content (message arguments) is most persuasive. According to the *elaboration likelihood model* (see Petty, Cacioppo, and Schumann, 1983), under conditions of high involvement with the ad message, consumers engage in thoughtful processing of the information in the ad and generally require strong logical arguments in favor of the advertised brand in order to be persuaded to choose the brand (central route to attitude change). When there is low involvement, persuasion is aided by repetition and peripheral cues (like a celebrity endorser) that help increase the likability of the ad and generate positive perceptions of the brand

(peripheral route to attitude change). Under low involvement, attitude formation can occur after actual purchase (Krugman, 1968; Haley and Baldinger, 2000).

Attitudes, and changes in attitudes, are better predictors of sales than is mere recall of an advertisement (Wells, 1997). Research also indicates that attitudes changed via the central route to persuasion are more persistent over time, more resistant to change when attacked, and more predictive of purchase behavior compared to attitudes changed via the peripheral route (Petty, Cacioppo, and Schumann, 1983; Wells, 1997).

The optimal number of exposures needed to influence purchase choice depends upon a range of factors including whether the brand is an established or new product, brand dominance/market share, brand loyalty, length of purchase cycle, target market, message complexity, message uniqueness, new versus continuing campaign, clutter level, share of voice, scheduling (continuous or pulsed), and number and type of media (Ostrow, 1984). However, some research suggests that sales can occur after just one exposure to the ad message (Jones, 2002) and that, in general, the number of exposures needed is small – two to three exposures (Krugman, 1968; Tellis, 2004).

Creative content. The creative content of advertising is crucial to its effectiveness. Research in this area cannot provide a definitive set of guidelines as to what creative execution is most persuasive since the effectiveness of an advertisement depends upon many factors including brand familiarity, message complexity, and the novelty of the creative content. The attractiveness and credibility of the source, message elements such as type of appeal, strong or weak arguments, and other characteristics, such as length, size, color, layout, and sound, all impact the extent to which consumers are persuaded to purchase the brand (see Stewart and Koslow, 1989; Tellis, 2004). However, some general findings regarding creative content indicate that (i) advertising is more effective when the brand name appears at the beginning of an ad rather than at the end (Baker and Honea, 2004); (ii) rational appeals (strong arguments, expert sources) are more effective in new-product markets while emotion-based

appeals are more effective in mature-product categories (Chandy *et al.*, 2001; MacInnis, Rao, and Weiss, 2002); (iii) celebrity endorsers are more effective under conditions of low involvement than high involvement (Petty, Cacioppo, and Schumann, 1983); and (iv) comparative advertising is most beneficial for new brands that compare themselves to established brands rather than the reverse (Grewal *et al.*, 1997).

CONCLUSION

Companies spend millions of dollars a year on advertising. According to the publication Media Matters (2007), the average person is exposed to about 600 ads per day. Political candidates want our votes, manufacturers and retailers want us to buy their brands, and nonprofit organizations want us to support their causes. Brands, ideas, and people constantly compete for our attention. Effective advertising breaks through this clutter and gets us to respond to the advertiser's message.

It is the job of advertising to persuade – to create clear, unique, and desirable associations that lead to preference for the brand and, ultimately, purchase. Effective advertising works through a hierarchy of effects that generates cognitive and affective changes in an individual's perceptions, beliefs, and attitudes. These mental processes enhance the advertised brand's value and stimulate sales. The process is not automatic. The ability of advertising to drive sales is tenuous and requires careful strategic planning and execution to be effective. However, effective advertising can build brand loyalty and lead to higher profitability, the generation of corporate goodwill, and reduced costs of marketing for the firm.

brand equity

Jacqueline J. Kacen

INTRODUCTION

In 2009, the Coca-Cola brand was valued at \$68.7 billion dollars and it was the world's most valuable brand (www.interbrand.com). The brand name alone, an intangible asset, accounted for 51% of the stock market value of the Coca-Cola Company (Interbrand, 2004). Coca-Cola is a brand with equity. Coca-Cola not only illustrates the value of a brand name but also demonstrates the importance of brands to a company's financial well-being.

The term *brand equity* came to public attention in the 1980s. It was first used by advertising practitioners to capture the idea that a brand had value to customers and because of this, the brand had financial value to the firm due to expected future sales (Barwise, 1993). In the late 1980s, quantifying the financial value of the brand became more important. Financial markets were recognizing the increasing gap between companies' book values and stock market valuations, as well as noticing the premium prices paid above stock market value during the mergers and acquisitions taking place. Large amounts of goodwill on balance sheets needed to be accounted for in an acceptable way (Feldwick, 1996; Murphy, 1990).

DEFINITION OF BRAND EQUITY

Brand equity is the "value of the brand" (American Marketing Association, 2009). A brand is "a name, term, design, symbol, or any other feature that identifies one seller's good or service as distinct from those of other sellers" (American Marketing Association, 2009). In general, brand equity can be thought of as a set of brand assets and liabilities linked to a brand, its name and symbol, that add to or subtract from the value provided by a product or service to a firm and/or that firm's customers (Aaker, 1991). Value is assessed from both the customer and managerial (i.e., financial) perspective. From a customer perspective, brand equity is based on consumer attitudes about positive brand attributes and favorable consequences of brand use. From

a managerial perspective, brand equity is the incremental cash flows which accrue to branded products over and above the cash flows which would result from the sale of unbranded products (Simon and Sullivan, 1993). From a financial markets perspective, brand equity is the sum of future profits, discounted in each period by a risk-adjusted interest rate, that result from associating that brand name with particular products or services (Simon and Sullivan, 1993).

WHY BRANDS ARE IMPORTANT

Customers like brands because brands provide assurances of quality, reliability, and consistency. Brands reduce perceived risk and allow people to shop quickly and confidently, saving time and energy on purchase decisions. Brands provide emotional rewards and experiential pleasure (Kapferer, 2008). Through brands, individuals can construct a self-concept and convey that concept to others.

Manufacturers benefit from brands as well. Brands cannot be copied by competitors, allowing manufacturers to command higher prices for preferred brands, obtain a larger market share, and spend less on promotional expenses such as advertising and price promotions (Shocker and Weitz, 1998). In addition, customer demand for the brand means manufacturers are better able to obtain distribution and cooperation from channel intermediaries. Customer preference for the brand can lead to a strong loyal customer franchise, more reliable demand forecasts, and expectations of cash flow from future sales. Last, a successful brand can be leveraged to increase sales and revenues for the firm through geographic market expansion and brand extensions.

Channel intermediaries, such as wholesalers and retailers, like brands because they allow for easier entry into markets, higher sales, and the opportunity to build loyalty at the store level.

HOW BRAND EQUITY IS MEASURED

The brand name and what it represents are a company's most important assets; a brand is the basis of competitive advantage and future revenue streams (Aaker, 1991). It is clear that brands help generate sales, and that sales

2 brand equity

generate revenue and profits, and that long-term revenue is earned through repurchase and customer loyalty. It is also evident that the financial value of a brand is a consequence of the value customers place on the brand.

Measuring a brand's equity is a useful exercise to firms not only because it allows firms to assign a financial value to the brand for purposes of balance sheet accounting and other financial transactions but also knowing a brand's equity can help guide marketing strategy and tactical decisions, it can help managers assess the extendibility of the brand name to new products and new markets, it can help managers evaluate the effectiveness of their marketing decisions, and it can track a brand's health over time, and against competitive brands (Keller, 1993).

Many methods have been proposed to value a brand. These approaches are generally financially driven methods or research-based methods. Financially driven approaches include the cost-based value of the brand—that is, aggregate expenditures incurred developing the brand including research and development, marketing, advertising, and employee training costs (Aaker, 1991), the residual market value of the brand after other sources of value have been accounted for (Simon and Sullivan, 1993), the ratio of the brand's price to its competitor's price when both products are equally desirable to consumers (Crimmins, 1992), net present value of the price premium the brand commands over unbranded, generic or competitive brands (Aaker, 1991), acquisition value of the brand (Brasco, 1988), and net present value of the brand's future expected earnings (Brasco, 1988).

Market-level indicators of brand value—a loyal customer base, price premiums, and sustained market share leadership—are clearly the result of consumer-level effects. One may conceive brand equity as composed of consumer brand equity leading to market brand equity. The associations and beliefs the consumer has about the brand (brand image) and the strength of the consumer's attachment to the brand (brand loyalty) lead to positive market outcomes such as market share leadership, price premiums (brand strength) and ultimately, the financial value of the brand as a separate asset on a balance sheet (brand value).

Consumer-based research methods include measures of consumer perceptions, attitudes, awareness, knowledge, familiarity, preference, purchase intentions, satisfaction, loyalty, purchase share, and repurchase rates. The hierarchy of effects model is a useful framework for understanding customer-based brand equity (Agarwal and Rao, 1996). The hierarchy of effects model suggests that consumers pass through different stages, from exposure to the brand to intention to buy, before making a purchase. Consumer brand equity begins with brand awareness, and progresses to perceptions and associations relating to the brand, preferences for the brand, choice intentions, and ultimately, purchase.

Brand awareness can be assessed based on measures of unaided recall, recognition, or familiarity with the brand name. Without awareness, a brand cannot become part of the consumer's consideration set and no purchase can take place, so brand awareness is a critical first step to building brand equity. The associations and beliefs a consumer has about the brand comprise the brand image and represent a deeper level of brand knowledge. Brand image can be assessed through measures of perceptions of quality, specific beliefs about the brand on key attributes, and perceived differences with competitive brands. Highly valued brands are perceived as superior on some valued attribute. Central to building a valuable brand is the ability of the firm to develop and nurture clear, unique, and desirable brand associations. Measures of brand preference include the consumer's overall evaluation of the brand, consumer willingness to pay a premium for the brand, and loyalty or share of category purchases. Consumer purchase intention measures include likelihood of purchase or selection from a choice set. Consumer-based brand measures are often collected via survey or consumer panels and as a result, can be costly to obtain and are subject to the potential biases and errors inherent in survey research. However, consumer measures are necessary and critical antecedents to market-related measures of brand equity. A firm achieves higher market share or price premiums because of the perceived value of the brand to consumers.

Customer-based measures of equity lead to brand strength in the marketplace. Brand

strength can be thought of as consumer demand for the brand relative to competitive offerings. Brand strength is a behavioral outcome of the perceived value a brand holds for consumers. It is captured by measures of competitive superiority including market share leadership, market penetration, share of requirements, and price premiums. In essence, brand strength is evidenced in the increased volume and/or increased margins a firm enjoys compared to sales of other brands or unbranded products in the category.

Brand strength is a precursor to brand financial value – a monetized measure of brand equity such as the value of the brand on a balance sheet or the acquisition value of the brand.

Brand image, brand loyalty, brand strength, and brand financial value are not independent of each other. But at the same time, there is no empirical evidence to support an assumption of causal linkages between these four concepts. Brands can score high on consumer measures of awareness, preference, and purchase intention and yet perform poorly in a competitive marketplace. Establishing empirical links between consumer-based measures of brand value and financial-market based measures of brand value – especially future financial performance of the brand – remains a challenge for researchers in the area of brand equity.

CONCLUSION

Brand equity is an important concept. The concept of brand equity represents the combined effect of customer, firm, and competitive market decisions on the value of a brand. Firms that successfully leverage the value of their brands generate greater sales and profits. While brands are strategic assets and the source of competitive advantage for firms, brand equity is a measure of that success.

advertising media selection

Kyle Krueger and Lawrence Soley

Advertising media selection is a major component of the media planning process performed by professionals in the advertising industry. It is the process of selecting the appropriate media (e.g., magazines) and vehicles (e.g., *Sports Illustrated*) to reach the target market (e.g., men, aged 25–54) of an advertising campaign. The process consists of making quantitative decisions, such as determining the most cost-efficient media and finding vehicles with a high composition of the target audience, as well as qualitative decisions, such as choosing media vehicles that provide an appropriate editorial environment for the product being advertised. Media planning is done to most efficiently achieve the media objectives of the campaign, such as exposing a percentage of the target audience to an advertisement or exposing the target audience to a certain number of advertisements.

Media objectives are frequently stated in terms of reach and frequency. Reach consists of the number of different prospects in the target market who will be exposed to the advertising campaign at least once. Reach is often stated as the percentage of the target market exposed to the campaign (e.g., 60%). Frequency refers to the average number of times each prospect will have the opportunity to be exposed to advertisements (e.g., 4.2 times) within a measured period of time. For branded products, it is believed that at least three exposures are necessary for a campaign to provide effective frequency. Generally, the first exposure generates some familiarity with the campaign message. The second exposure generates recognition; that is, that the message has been seen before. After the third exposure, the message begins generating recall (Krugman, 1972) (see ADVERTISING EFFECTIVENESS).

A summary measure of reach and frequency is called gross rating points (GRPs), which is the overall gross duplicated coverage of the target market that is reached at least one time, expressed as a percentage. GRPs is calculated as reach \times frequency. Thus, a campaign generating 60% reach and a frequency of 4.2 would generate 252 GRPs.

GRPs is a simple way of estimating the number of exposures that an advertising campaign will generate, given the advertising campaign's budget (see THE ADVERTISING BUDGET). For example, prime time network television costs average \$27 965 per rating point (SQAD, 2008). Thus, an advertising campaign with a budget of \$20 million should be capable of buying at least 870 GRPs in prime time television. Media planners use this estimate as a starting point, attempting to find more efficient ways to reach the target market, as well as assessing what levels of reach and frequency are needed to achieve the communication goals of the campaigns.

Total impressions are another metric used to estimate the number of exposures generated by an advertising campaign. Unlike GRPs, which are expressed as a percentage, impressions are stated in terms of numbers of individuals (or homes). Total impressions can be calculated in two ways. The first method is to multiply the GRPs delivered by the population of the target group. A schedule that generates 252 GRPs against a target population of 1 000 000 prospects will produce 2 520 000 impressions. The second method is by adding the audience exposed (number) to each advertisement in the media schedule. Like GRPs, impressions signify the gross delivery of media schedule without regard to duplicate exposure (Surmanek, 1996).

To generate additional reach and frequency, media planners often use a media mix. A *media mix* refers to the use of two or more different media types in one advertising campaign. The most common reasons a media mix is employed are to reach prospects not reached by the first media type, to supply ancillary repeat exposure in a second medium after the optimal reach is achieved in the first medium, and to extend the efficacy of campaign creative through other media types conducive to the messaging. The basic assumption is synergistic when two media types are combined, the effect produced by the sum of parts is greater than the same two media used alone (Surmanek, 1996).

Another metric often used in the comparison of media vehicle or schedule efficiency is cost per thousand (CPM). CPM is the cost of delivering 1000 impressions against a defined audience group. For example, a full page ad

2 advertising media selection

which costs \$25 000 in a magazine with 500 000 subscribers has a CPM of \$50, and is deemed more efficient than a similar sized ad that costs \$15 000 in a magazine with 250 000 subscribers and has a CPM of \$60.

Communication goals are statements about what the content of the advertising messages seeks to communicate. Communication goals are often stated in such terms as “prospects who recall the selling points of the product” or “become aware of where the product can be purchased.”

Frequency is the foundation for media planning, as some advertising campaigns require higher levels of frequency to communicate effectively than others. If the needed frequency for a campaign is not generated, the campaign’s communication objectives will not be achieved. Ostrow (1984) developed a model for estimating the needed frequency of an advertising campaign, which is sometimes known as the “3M’s” of media planning. The 3M’s are message factors, marketing factors, and media factors. Message factors consist of such things as the complexity of the message, the uniqueness of the message, and the length of the message. More complex messages, such as a message communicating multiple sales points, require higher levels of frequency than messages that have a simple message, such as generating brand name awareness. Although uniqueness is subjective, there is no question that unique messages stand out and require lower levels of frequency to get the message noticed and recalled than less unique messages. Similarly, campaigns using smaller print ads will require a higher level of frequency than smaller ads. Roper Starch studies have shown that full page ads generate greater attention than ads that are fractions of a page (Starch, 1966; Franke and Huhmann, 2004).

Marketing factors include the frequency of competitors’ campaigns, the purchase cycle of the product, brand loyalty, and the characteristics of the products’ target market. Generally speaking, if competitors have a heavy mass media presence, a higher level of frequency for a campaign is needed to break through this presence. Brands that have low brand loyalty need a higher level of frequency than brands that have high brand loyalty. Products that have a quick

turnover, such as branded food products, need a higher level of repetition than products that are consumed less frequently, such as shoes. In addition, some target groups need higher levels of frequency than other target groups. Generally speaking, better-educated groups can process and retain advertising messages when exposed less frequently than less well-educated groups.

Media factors include the types of media used, the clutter in the media, position, and attentiveness to media. In terms of media, audio messages generally require a higher level of frequency than print or Internet messages, which allow prospects to reread messages if they fail to understand or remember a message component. Clutter refers to the number of messages surrounding the advertiser’s message. Generally, the higher the clutter of the media, the higher the frequency needed for a campaign. Thus, higher levels of frequency are needed for campaigns using daytime television, which airs a greater number of commercials than prime-time television does. Moreover, campaigns that place ads in magazines that are highly cluttered or that bank ads need a higher level of repetition than campaigns that are not so cluttered. Banking is when magazines place advertisements together in specific parts of the magazine, separating them from the feature stories, as *National Geographic* does. Position refers to the location of the ad relative to others. Generally speaking, some positions, such as the covers and first five pages of a magazine, generate higher attention from readers than other positions. Additionally, ads positioned on the right-hand page are generally preferred over left-hand placements. Campaigns that are in these positions can use a lower level of frequency than those in other positions. Lastly, some media generate higher levels of attention than other media. Attentiveness to daytime television and reality shows is generally lower than attentiveness to prime time television and dramatic shows (Media Dynamics, 2009; Soley, 1984).

There are other ways to set frequency levels for campaigns. One is empirically, which means pretesting the campaign to determine the type and frequency of ads needed to achieve the communication goals of the campaign. There are commercial research services such

as Behaviorscan that will pretest messages for clients.

Much of the data for setting reach and frequency for media campaigns are available from syndicated research services, such as Simmons Market Research Bureau (SMRB) and Mediamark Research, Inc. (MRI). As an example, media planners can examine competitors' advertising activities using data supplied by such companies as TNS Media Intelligence and VMS or Internet-specific advertising activities using Nielsen NetRatings and comScore. Media planners can estimate levels of brand loyalty for brands with data supplied by SMRB. SMRB and Information Resources Inc. (IRI) also provide information on attentiveness to television dayparts and time spent reading magazines, allowing media planners to evaluate these media when setting advertising frequency levels.

In addition to providing data for making vehicle selection decisions, syndicated research firms such as MRI and SMRB can also be used for analyzing media consumption patterns among the target market, which is necessary for winnowing down available media types and the array of potential vehicles. This winnowing process is often done with a media quintile analysis. In a media quintile analysis, which segments people into a five-level spectrum of media consumption patterns, the indexes for a target group are compared against a base control group (which will have a 100 index). This comparison can provide media planners a starting point for media mix selection. For example, if the average adult uses television at a 100 index, and the heaviest users of TV among the target group (e.g., men, aged 25–54) use television at a 150 index, then the target group is 50% more likely to use television than the average adult. This medium would therefore be a potentially useful medium to include in the media mix. Indexes are also useful in winnowing down choices among media vehicles. For

instance, the selection of radio formats can be assisted by the comparison of indexes. A format that has a 175 index against a target group is thought to be a better choice than a format that indexes at a lower number, outside the confines of cost and other planning parameters.

In summary, an advertiser's media objectives can be achieved through a proficient use of the tools available in the media planning process. Media planners combine quantitative data, such as syndicated research indices, and qualitative data, such as the education level of the target audience, in crafting a media that maximizes the efficiency of the media budget, and effectively targets the proper audience. A successful media plan combined with appropriate creative messaging leads to preference for an advertiser's brand and sales of an advertiser's products or services.

emotional intelligence

Paula C. Peter

INTRODUCTION

Emotional Intelligence (EI) refers to the cognitive ability to correctly perceive, use, understand, and regulate emotions in the self and others (Mayer and Salovey, 1997). Although several definitions and measurements of EI exist, current literature in the field reinforces the existence of EI as a valid theoretical construct and supports its predictive validity in different domains.

Within the field of advertising and marketing communications, there is a well-established interest in the role that emotions play in advertising appeals. From the elaboration likelihood model (Petty and Cacioppo, 1986), to the use of sex, fear, and humor appeals in advertising, the past 30 years of marketing research and practice has highlighted the prominence of emotions in advertising appeals. However, there are relatively few studies that have examined factors that might moderate the persuasive effect of emotional appeals. EI might be considered as one of them.

EI, as the ability to correctly interpret and process emotional information, is expected to contribute to quality decision making as suggested by Goleman (1995) and supported by Damasio's work on neuroscience (Damasio, 1994). Emotionally intelligent individuals have a greater ability to recognize and understand emotions, which is necessary to differentiate the advertising appeal from the substance of the message. EI could benefit consumers in the interpretation of marketing communications, and could also benefit the marketers as they attempt to understand which emotional appeals are most effective in communicating messages about their product, service, or idea. The goal of this article is to provide an overview of EI in terms of its origin, theory, and measures in order to stimulate an area of research (EI) that has the potential to contribute to marketing communications and advertising.

A HISTORICAL PERSPECTIVE

EI, already defined of the beginning was modeled in the early 1990s with work by Peter Salovey and John Mayer. Salovey and Mayer (1990) formed the basis for most of the academic research related to EI. They defined EI as *a cognitive ability that allows people to monitor, discriminate, and use one's own and other's emotional information in thinking and action*. They built their theory upon previous work on intelligence by Bar-On (1988, in Salovey and Mayer 1990), Gardner (1983, in Salovey and Mayer 1990) and Thorndike (1920, in Salovey and Mayer 1990). However, the construct did not receive much attention until 1995, when Daniel Goleman published his book "Emotional Intelligence: Why it can matter more than IQ". Although this book made the construct popular, it did not lead to a standardized definition of EI as originally formulated by Salovey and Mayer (1990); Mayer and Salovey (1997). In fact, the high level of interest in EI resulted in the creation of a variety of definitions of EI and what it might predict and also contributed to the formulation of different EI models.

MODELS OF EI

The field of EI currently recognizes three basic models of EI: the ability model, the mixed model, and the trait model. However, the trait model is often considered a subset of the mixed model.

All models are founded on the basic premise of emotional intelligence but they differ in terms of definition and measurement of the construct. Emotional intelligence, as originally defined by Salovey and Mayer (1990), falls under the ability model of EI, where the focus is on emotional abilities measured by maximum performance on an ability test. In contrast, the mixed models and trait models focus on competencies, skills, and traits that are not measured through ability tests but through self-report measures instead (e.g., Schutte *et al.*, 1998).

The mixed model and trait model focus on a mix of constructs not necessarily related to emotions or intelligence. The mixed model focuses more on the prediction of EI, while the trait model focuses more on trait emotional intelligence within a personality framework. Work by Goleman (1998) on performance, and Bar-On

2 emotional intelligence

(2006) on health are examples of a mixed model approach toward EI. Goleman defines EI as a set of different competencies that drive success in the workplace. Bar-On defines emotional intelligence as an ability to cope with environmental demands and relate to ourselves and others. Schutte *et al.*, (1998) developed a self-report measure of EI that falls within the personality framework related to EI (trait model).

EI, as defined by the trait model and mixed model, has been criticized as not related to emotional competencies but rather to self-reported emotional traits instead. This criticism, when combined with a multitude of operationalizations of EI, has contributed to a general skepticism toward emotional intelligence and its predictive validity. Self-reporting approaches to EI are considered to be appropriate measures of self-perceived EI, however, they are not appropriate to measure EI as cognitive ability.

In contrast, emotional intelligence as the cognitive ability to perceive, use, understand, and regulate emotions (Mayer and Salovey, 1997) has been conceptualized and measured using the ability model. Since the purpose of this article is to introduce emotional intelligence as an individual cognitive ability to correctly perceive, understand, and elaborate emotional information in advertising appeals, the focus will be on emotional intelligence as defined by the ability model (Mayer and Salovey, 1997).

THE ABILITY MODEL OF EI

The ability model represents the original model of EI and it was formally proposed by Mayer, DiPaolo, and Salovey (1990) after the conceptualization of EI by Salovey and Mayer (1990). The model was subsequently refined by Mayer and Salovey, 1997. Mayer and Salovey (1997) proposed EI as a cognitive ability that can vary from individual to individual. This cognitive ability is further subdivided into four specific branches, which are organized hierarchically:

1. Perception of emotions – the ability to recognize and identify emotions in the self and others.
2. Use of emotions – the ability to use emotions to facilitate thoughts and solve problems.

3. Understanding of emotions – the ability to understand and interpret blends of emotions.
4. Regulation of emotion – the ability to regulate emotions in self and others.

Measures of EI. Theoretical and empirical research on the four branches of cognitive abilities resulted in the development of the most widely recognized measure of EI: The Mayer-Salovey-Caruso Emotional Intelligence Test (MSCEIT). The MSCEIT is a proprietary cognitive test of EI designed for people aged 17 and older and modeled on ability-based IQ tests. It consists of 141 questions and provides respondents with 3 different scoring subsets: an overall EI score; “area” EI scores; and “branch” EI scores. The two area EI scores are defined as the experiencing area of EI (formed by the perception and use of emotions), and the reasoning area of EI (formed by the understanding and managing of emotions). The branch EI scores measure the perceiving, using, understanding, and managing cognitive abilities previously outlined.

The MSCEIT interpretation of EI at these three major levels has shown good reliability, face validity, and discriminant validity with different measures associated with EI (Mayer, Salovey, and Caruso, 2002). The MSCEIT assesses emotional abilities with answers deemed correct by consensus score or by expert score.

Using the MSCEIT as a foundation, Kidwell, Hardesty, and Childers (2008) developed the Consumer Emotional Intelligence Scale (CEIS). The CEIS is a nonproprietary context-based measure of EI that relies on the same EI cognitive branches as originally defined by the MSCEIT. The scale is shorter (18 items vs 141) and offers an alternative to MSCEIT of assessing emotional abilities in the consumer domain. The CEIS has been related to higher quality decision related to food and general product choices (Kidwell, Hardesty, and Childers, 2008) but is not meant to be a substitute for more general measures of EI (i.e., MSCEIT). Owing to the relative newness of the CEIS, further research is required to validate the reliability, face, and discriminant validity of CEIS in the consumer domain.

What does EI predict? Mayer, Roberts, and Barsade (2008) have recently offered a comprehensive review of studies that examined the predictive validity of EI as measured by the MSCEIT. On the basis of their analysis, they suggest that EI is positively related to better social relations for children and adults, social acceptance, family and intimate relationships, academic achievement, social relations during work performance and in negotiations, and psychological well-being. They also propose EI to be positively related to career interests, attitude toward money, money gained in negotiations, emotional eavesdropping, and emotional forecasting (Mayer, Roberts, and Barsade, 2008).

The authors suggest the importance of maintaining proper controls for age, gender, cognitive intelligence (IQ), and personality variables while making predictions of EI in these domains. Otherwise, empirical evidence may reveal contradictory findings.

Can we learn and teach EI? EI competencies build on emotional knowledge, and emotional knowledge seems to be relatively easy to obtain and promote (Mayer, Salovey, and Caruso, 2004). However, very few studies provide empirical evidence of this phenomenon. This is probably due to the novelty of the construct, as well as a lack of clear understanding of how EI training programs should be developed. Moreover, the tendency is to use short-term training programs to test for the possibility of learning and/or teaching EI when a longer term perspective would be more appropriate. Mayer, Salovey, and Caruso (2004) provide an overview of several longitudinal studies and conclude that a developmental trend in EI exists and that further research is warranted in this area.

Criticism and future of EI. A great deal of criticism about EI has been related to its elusive and broad conceptualization, as well as its association with self-report measures. However, it is important to note that these specific criticisms do not apply to the ability model of EI, as this model is deeply rooted in psychology and has a well-established theoretical and empirical framework. Nevertheless, other legitimate criticisms of the ability model do exist.

First, the MSCEIT has been questioned as genuine measure of intelligence since it is not measured by objectively correct responses. As mentioned above, the MSCEIT offers a scoring based on answers deemed correct by consensus score (the norm) or by expert score. The option of consensus means that the correct response is the one the majority of the sample ($N = 5000$, Mayer, Salovey, and Caruso, 2002) has endorsed. Therefore, the creation of questions that only high emotional intelligent individuals can solve becomes impossible by the consensus criterion. The expert scoring might be suggested as an alternative to avoid criticism related to the consensus criterion. In the expert scoring, the correct answer is deemed correct by a pool of researchers who have expertise in emotions.

Second, research to date on EI lacks consistency in terms of the predictive validity of EI. A more systematic approach to EI research must be developed in order to determine the predictive validity of EI. Further, the relationship between EI and its areas, branches, and criterion variables should be hypothesized on the basis of a theoretical framework that calls for the salience of the cognitive ability to perceive, use, understand, and regulate emotions.

The validity of EI relies on its nomological framework, which includes a well-established theoretical (ability model of EI) and empirical (MSCEIT) framework. The future of EI, as a field of research, depends on a systematic approach toward the understanding of the linkages among the theoretical and empirical framework of EI.

APPLICATIONS OF EMOTIONAL INTELLIGENCE IN ADVERTISING

The majority of research and practice related to advertising and marketing communications suggests that emotional appeals are effective in attracting consumers' attention and may even build brand connections. Thus, marketers are interested in the identification of the appropriate evoked emotions to be linked to the brand, product, service, or idea. If marketers tap into the appropriate emotional connections, they stand a much better chance of developing a long-lasting relationship between their brand and its users. Conversely, a failure to create the appropriate

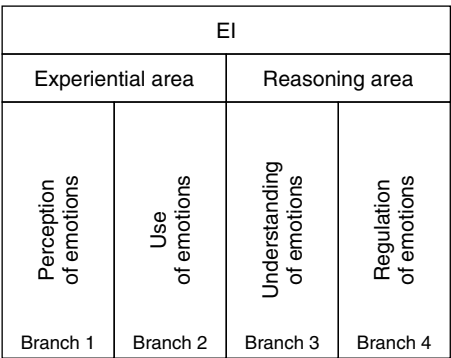

Figure 1 An illustration of the Ability Model of EI as measured by the MSCEIT.

emotional connections could lead to less of an impact and potentially drive consumers away, diminishing the brand value of their product, service, or idea.

Marketers could also take advantage of studies relating to how consumers use emotional information to actually make brand, product, or service decisions. EI, as defined by the ability model, represents a reliable tool for measuring individual differences in consumers' ability to use and process emotional information.

EI must be viewed as a multidimensional construct (Figure 1). For example, the perception of emotions (Figure 1, Branch 1) might be important in order to understand which features of the product emotionally appeal to the consumer, while the understanding of emotions (Figure 1, Branch 3) could be useful in understanding which emotions are most meaningful to consumers when they establish a connection with a specific product or brand.

These are only a few possible suggestions related to the application of EI in advertising and marketing communications. EI has the potential to contribute to a well-established literature that has considered both the role of emotions and logic in decision making (e.g., Damasio, 1994). Research on the role of EI would likely

benefit the marketer and the consumer, as well as increasing the effectiveness of advertising and marketing communications.

brand extensions and flanker brands

Youngseon Kim and Tina M. Lowrey

BRAND EXTENSIONS

A brand extension involves a company using an existing brand name to introduce a new product (e.g., Keller, 2008). That is, it is one of many new-product launch strategies. A brand extension stretches a well-established brand name for a new-product offering into either a totally different product category or in the same product category for a new market segment. The existing brand is called the parent brand or the core brand because it gives life to a brand extension (Keller, 2008). This implies that brand extensions fall into two general categories: category extension and line extension (Farquhar, 1989). Category extension occurs when a company uses the parent brand to launch a new product in a different product category from the one that it currently serves (e.g., Fendi watches, Jeep strollers, and Honda lawn mowers). Line extension occurs when a company applies the parent brand to a new product that targets a different market segment within a product category that the company currently serves (e.g., Ralph Lauren purple label and Head & Shoulders[®] dry scalp shampoo).

Brand extension has been a popular strategy for continued growth for major companies that already have a strong brand in the markets they serve. Recently, 82% of new product launches were identified as either type of brand extension (Simms, 2005). This trend may be because brand extensions are low-risk models in which a well-built brand name and its image can be transferred to a new product, compared to the high risk of launching a new product under a totally different brand name. Thus, brand extensions buffer the costs and risk associated with launching a new product. A familiar and trusted brand name signals credibility and quality to consumers and elevates the likelihood that they will try the extension product (Braig and Tybout, 2005). In general, brand extensions can help build/maintain a company's brand equity. They leverage brand assets and create synergy by generating more chances for brand exposure and associations in different contexts.

In addition, they increase profitability by serving the customer with new products in more than one product category (Aaker and Joachimsthaler, 2000). Thus, well-planned and well-implemented extensions not only bring out a number of advantages to marketers in a new product introduction, but also benefit the parent brand.

A vertical extension is a different type of brand extension which does not simply fit into either category of brand extensions mentioned above. It includes sub-branding and super-branding targeted at different market segments in the same category. In this sense, vertical extensions can be said to belong to line extensions except that they have an additional brand name endorsed by the parent brand (e.g., Courtyard[®] by Marriott). Marketers introduce low-priced versions of their established brand name products for more value-conscious segments (sub-branding) whereas they attempt to ladder up their brand to up-market through brand extensions in order to serve a more premium market segment (super-branding) (Keller, 2002). The rationale behind vertical extensions is that the parent brand's equity can be transferred in either direction in order to appeal to consumers because the parent brand has a role as endorser for the new offering (Keller, 2008).

Sub-branding (e.g., Fairfield Inn[®] by Marriott, Marc by Marc Jacobs) can be used as a means to distinguish lower-priced entries. Sub-branding can reduce the risk of potential failure of the extension. However, downward extension of prestige brands can face resistance from current owners because they desire brand exclusivity (Kirmani, Sood, and Bridges, 1999). Super-branding can be used to indicate a noticeable, although presumably not dramatic, quality improvement (e.g., GE Profile[™] or Levi's[®] Vintage). The upward extension can upgrade brand image because a more premium version of a brand tends to develop positive associations with the brand (Keller, 2008).

Considering the high failure rate of new products (e.g., only one or two out of ten new products are successful and the vast majority of them are withdrawn from the market within a year; Braig and Tybout, 2005; Keller, 2008) brand extensions definitely make new-product

2 brand extensions and flanker brands

acceptance easier if the parent brand has been well known and well liked in the market that it has served (Keller, 2008). Consumers can make inferences and expectations about the likely quality and performance of a new product, based on what they already know about the parent brand (the degree to which they feel the knowledge is relevant to the new product) (Keller, 2008). This benefit enables a reduction of risk perceived by customers, distributors, and retailers. It can lead to a decrease in the cost of gaining distribution and trial, improve the efficiency of promotional expenditures, and so on. In addition to facilitating acceptance of extensions, they can also provide feedback benefits to the parent brand and the company as a whole. They can enhance the parent brand image by improving the strength and favorability of brand associations. The enhancement of the parent brand also leads to improvement of perceptions of company credibility, expertise, and trustworthiness (Aaker and Keller, 1990). In a long-term perspective, extensions may help fine-tune the company's core benefit proposition and business definition, which is a key factor in gaining new customers in the company's brand franchise and increasing market coverage.

Despite the many number of benefits of brand extensions mentioned so far, they are not always easy to execute in the competitive business environment. Thus, marketers should be able to address questions ranging from whether to extend the brand to when, where, and how to extend it before making any strategic decision about launching a brand extension. Poorly executed extensions can dilute brand associations, weaken brand power, and reduce the clarity of the offerings. When a brand is tied closely to a certain product class and represents it, the brand's potential to stretch is limited. For example, brands such as Kleenex® and Clorox® Bleach may not extend too far beyond their basic product areas because they are so attached to a specific product and its attributes (Aaker and Joachimsthaler, 2000). In contrast, brands with credibility and intangible associations are more likely to extend to new categories because those intangibles make sense to consumers in a wide variety of contexts (Park, Milberg, and Lawson, 1991; Schultz and Schultz, 2004). Extreme examples of this can be found in

Virgin brand. The brand has been stretched from record sales to colas to hotels and airlines. How were those extensions possible? It does not seem to represent expertise in one specific field; instead it may be a way of managing, a way of serving customers, and a view of the world that people seem to like (Schultz and Schultz, 2004). In contrast, Park, Milberg, and Lawson (1991) showed that function-based brands have more difficulty with brand extension than prestige-based brands (e.g., Timex vs Rolex).

What are the basic guidelines about brand extensions? Successful brand extensions can be made when the parent brand is viewed to have favorable associations and there is a perception of fit between the parent brand and its extension (Keller, 2002). The fit can be found in many different parts of a parent brand and its extension, ranging from not only product-related attributes and benefits, but also non-product-related attributes and benefits such as common usage situations or user types (Aaker and Joachimsthaler, 2000). Wherever the base of fit judgment is located, consumers should be comfortable with the extension and sense a fit. The brand extension should offer an added value for consumers, thereby helping consumers understand why the new offering from the parent brand should be preferred to other brands (Aaker and Joachimsthaler, 2000). In addition, the new association between the parent brand and its extension should enhance brand equity. Marketing research should be conducted to explore three of these criteria for making a decision of whether the brand can be extended successfully (Keller, 2008).

Academic research and industry experience have discovered a number of principles leading to successful brand extensions. Keller (2008) recommends that marketers go over their brand extension strategies thoroughly by following the steps below, and apply their managerial judgment and consumer research findings in order to accomplish appropriate and successful brand extensions.

- Define actual and desired consumer knowledge about the brand (e.g., create mental map and identify key sources of equity).
- Identify possible extension candidates on the basis of parent brand associations and overall

similarity or fit of extension to the parent brand.

- Evaluate the potential of the extension candidate to create equity.
- Design marketing programs to launch extensions.
- Evaluate extension success and effects on parent brand equity. (Keller, 2008, p. 524).

FLANKER BRANDS

When a brand is attacked by a competitor with a value offer or unique position, any company takes such an attack seriously and responds. However, any careless response can jeopardize its image and brand equity (Aaker, 2004). A solution can be found through having a flanker brand. A flanker brand (also called a fighting brand) is a new brand launched in the market by a company with an established brand in the same product category. It is designed to fight a competitor, shielding the flagship brand from the fray (Giddens, 2002). The name “flanker brand” comes from a war metaphor. A flanker brand protects the flagship brand from a competitor that is not competing directly with attributes and benefits that the flagship brand has nurtured (Aaker, 2004). Ideally, a flanker brand should compete in the same category as the flagship brand without cannibalizing the flagship brand’s market share through targeting a different group of consumers. The objective of a flanker brand is to debilitate the competitor brand where it is positioned without compelling the flagship brand to divert its focus (Aaker, 2004). Broadly this strategy is called fighter branding or multibranding in the sense that it can help a company to occupy a larger total market share than one product could garner alone.

The brand portfolio of a company with flanker brands includes the following types of offerings: (i) a flagship (or premium) brand that offers high quality at a higher price; and (ii) one or more “value” brands offering a slightly lower quality or a different set of benefits for a lower price. One of the largest companies to use this strategy effectively is Proctor & Gamble (P>M). Tide[®] is an extremely well-established laundry detergent whereas Cheer[®] is a slightly lower quality detergent available at a value price, developed

brand extensions and flanker brands 3

to appeal to consumers who wanted a lower cost detergent. The sales of Tide[®] sales dropped slightly when the new brand, Cheer[®], was introduced, but the combined sales of Cheer[®] and Tide[®] were greater than the former sales of Tide[®] alone. Thus, the adoption of a flanker branding strategy by P>M let the company achieve a higher market share (Giddens, 2002).

Typically, the purpose of flanker brands is to create stronger points of parity with competitors’ brands so that more important (and more profitable) flagship brands can retain their desired positioning (Keller, 2008). Many companies are launching discount brands as flankers to better compete with store brands and private labels, and guard their higher end brands. Thus, it is true that developing a flanker brand offers a number of advantages to the company adopting the strategy. For example, a flanker brand helps gain more store shelf space for the company which leads to retailers’ increased dependence on the company’s products (Giddens, 2002). At the same time, a flanker brand helps mitigate the pressure of losing sales caused by cheaper store brands or private label brands available in almost every retail store chain, and grab “brand switchers” for a value offering by providing several different brands. Above all, the company and the flagship brand can be protected even if the flanker brand fails in the market because consumers will not readily associate it with the existing flagship brand.

However, flanker branding is not completely without risk. The risk is similar to that of launching a new brand. Introducing a new brand into the market is always expensive. Brand introductions need an ample amount of marketing communication expenditures as well as a great deal of consumer research. Thus, in some cases, companies try to reposition existing brands in their portfolios to play the flanker role instead of introducing a new brand. For example, P>M repositioned its one-time top-tier Luvs diaper brand to serve as a flanker to insulate the premium-positioned Pampers brand from private labels and store brands (Keller, 2008).

When marketers design flanker brands, they must be very careful. Fighter brands must not be so attractive that they take large amounts of sales away from their higher priced comparison

4 brand extensions and flanker brands

brands. At the same time, flanker brands should not be designed so cheaply that they negatively affect the other brands in the company's brand portfolio (Keller, 2008). Like brand extensions, flanker branding may not be for every player in the market, even if it may enable a company to protect its flagship brands from the attack of lower priced value offerings by the competitor.

CONCLUSION

A brand portfolio strategy guides how a company will manage different brands and branding elements to lead to long-term profitable growth (Calkins, 2005). Brand extensions and flanker brands can be said to be key players in building and managing a strong brand portfolio, viewed from the objectives and roles of each. A growth alternative is found when utilizing a strong brand through extensions (Aaker, 2004). Brand extensions involve leveraging tangible and intangible assets of a parent brand (or a core brand) for introducing a new product. Whether a company has a strong core brand is the first and most important base for stretching a brand into a new market. Unless a company has a strong and well-built brand to extend, it may be fruitless to invest in brand extensions. Thus, building a strong core brand is the first priority before pursuing any type of extensions. Once the strong core brand is built, extension opportunities are easy to find, and a brand extension from the strong core brand will add value through its favorable associations and reach current/prospective customers (Aaker, 2004; Calkins, 2005). A company also makes a strategic decision to move down market in order to access volume markets. This movement may result in an unsuccessful launch of a new product, as well as damage the company's brand image. In terms of maintaining a well-conceived brand portfolio, the company can separate a value offering from its core brand through sub-branding. However, the best option may be to reposition an existing brand in the company's brand portfolio, or to create a new one (Aaker, 2004). This movement is in line with flanker branding. With flanker brands, the company is more likely to protect its core market position without diluting the core brand image and garner more sales.

The role and business objectives of brand extensions are very different from those of flanker brands. Each of them is rooted in a different branding strategy in a company's brand architecture and portfolio. However, they are equally important in terms of protecting the brand equity that the company has achieved by bringing out greater customer share on the condition that they are well designed and implemented. Finally, strategic utilization of brand extensions and flanker brands in a company's brand portfolio will help achieve a company's business goal of long-term profitable growth by meeting the following marketing objectives based upon special roles of brands in the brand portfolio of a company: (i) to attract a particular market segment that is not currently being served by other brands of the company (Keller, 2008); (ii) to keep market position and protect flagship brands (Giddens, 2002); (iii) to broaden product offerings in order to appeal to consumers seeking variety who may otherwise have switched to a competitor's brand (Keller, 2008); and (iv) to achieve economies of scale in marketing communications, sales, merchandising, and physical distribution (Keller, 2008).

advertising and the integrated marketing communications (IMC) process

Youngeon Kim and Tina M. Lowrey

Integrated marketing communications (IMC) involves strategic synchronization of various forms of persuasive communication programs with customers and prospects over time (e.g., Schultz, 1993). The goal of IMC is to convey a company's marketing messages in a consistent and coherent manner through online and off-line communication channels. Thus, IMC deals with all sources of brand or company contacts that a customer or prospect has about the product or service as potential delivery channels for conveying messages. Advertisers utilize a myriad of tools such as advertising, public relations, direct marketing, interactive/Internet marketing, sales promotion, and personal selling in order to best communicate with their target audience. Advertising in traditional media played a key role in providing and managing the initial attempts at integrating different marketing communication tools in the 1990s (Percy, 2008). This key role seemed legitimate, considering the size of the budget allocated to advertising. However, since then, there have been shifts in the advertising and media industries from conventional advertising methods to multiple forms of communications, from mass media to more specialized (niche) media, which are centered on specific target audiences, and from advertiser-driven message transfer to consumer-driven message contagion, and so on. Thus, the strategic importance of IMC has become more widely recognized. In addition, the role or value of traditional mass-media advertising today is often questioned.

However, IMC planning and implementation does not necessarily shrink the role or value of advertising in general (Percy, 2008). Advertising was primarily placed in traditional mass-media such as television, radio, newspaper, magazines, outdoor, and direct mail. Nowadays, advertising messages are increasingly delivered through co-op marketing programs (i.e., cooperative marketing communication programs between a manufacturer and its retailers, or co-op advertising/joint promotions between

two brands. For example, when a company launches a campaign for a new brand, it tries hard to take advantage of the venues it can leverage in order to keep the new campaign running to communicate integrated and consistent messages at any possible customer contact point) and on the Internet. We can also find some advertising campaigns that contain a well-pronounced brand-building message as well as a promotional offer for a new product, all built to create an immediate excitement to buy (Percy, 2008). These are a few examples of how advertising effectiveness can be enhanced when paired with other promotion tools. They also show how advertising messages can be delivered more effectively and more efficiently throughout a fuller line of media channels, depending on the target audience and the marketing communication objectives.

The primary goal of advertising is to build brand awareness and brand attitude, which are fundamental factors for building a brand (e.g., Percy, 2008). If this is the company's major communication objective, advertising may lead the whole marketing communication program. Building a brand takes time. Thus, this is a long-term project. All other marketing communications should help build brand awareness and develop a positive feeling for the brand. That is the reason that IMC process and implementation are so critical in building strong brands. Brand messages should be developed to fit with the communication objective and should be conveyed in a consistent "look and feel" across media platforms at every consumer contact point over time, which ensures that everything included in an IMC campaign will send the same message (Percy, 2008). The key themes and visuals contained in advertisements should be embedded into other forms of marketing communication channels: public relations, direct mail, Internet presence, in-store communication, and so on. One of the most important and difficult tasks for IMC is ensuring consistency in executions so that the target audience is able to immediately identify any execution within a campaign and connect it to the brand in the end. In this cluttered and fragmented media environment, advertising in traditional media may have lost its power. However, it can still shine as a part of a well-defined IMC campaign.

luxury brands versus other brand categories

Kapareliotis Ilias

Brands are symbolic entities and powerful elements influencing cultures, societies, and generations. They play a pivotal role in everyday life from the different decisions to the choices people make every day. The branding concept appeared hundreds of years ago. Brands at that time meant differentiation from one cattle farmer to the other. The current brand definition has evolved from marks, names, logos, and product shapes. The definition evolved as the marketing strategies related to the brand were more focused to them. A brand symbolizes the guarantee and credibility that the consumer asks when purchasing. The brand is the final promise that a consumer will take after the final purchasing decision. The brand can thus be defined as follows: *A brand is a name, term, sign, symbol, design, or a combination of these that is intended to identify the product of a seller and to differentiate it from those of competitors.*

Branding has become very prominent over the last thirty years as a core marketing aspect and an important part of business strategy. As a modern concept, branding can be applied to anything from products to services, to companies, countries, and even individuals. Every brand has a unique characteristic of identity, promise, value, and differentiation. Additionally, there are brand elements that build the relationship between the consumer and the brand. The benefit is mutual for the consumer and the company as they both acknowledge the identity of each other. Consumers are delivered a certain promise not only of quality, but also of a unique experience. Thus the brand becomes not only a marketing tool, but also an intangible asset that guarantees profitability and future earnings.

Luxury goods have been developed over the last twenty years. The overall development of luxury brands is due to different factors. Some of them are due to the increase of income level in western societies, the need for differentiation, and the saturation of branded goods of the product category. Luxury brands give emphasis to the art of product design, innovation, and aesthetics. Branding for luxury products is based on design and creativity. Luxury brands

are striving for innovation, differentiation, and uniqueness. Luxury brands set the fashion trend for every category they belong to. Luxury brands try to combine the past and the future. The luxury brand logos combine luxury images and prestige. Consumers expect luxury brands to be innovative in all aspects and be trendsetters. Luxury brands are more customized to consumers' needs than regular brands. Luxury brands try to understand consumer's psychology, changing habits, and needs, and of course, have to be in the forefront of everyday life. The producers of luxury brands need to make an analysis of current trends and social or other changes influencing consumers and to produce products that will attract as many consumers as possible.

Luxury brands have been crafted through consistent and sophisticated strategies in the marketing field. They have a high acceptance from the global world and in special moments, cases, or circumstances consumers think that luxury brands might be the remedy for their conscious or unconscious problems. Luxury brands have some main core characteristics that differentiate them from the other brand categories. The differentiating characteristics of luxury brands in comparison with other brand categories are *strong brand image, differentiation, innovation, exclusivity, high quality, and high pricing.*

A HISTORICAL PERSPECTIVE

Branding was part of ancient trade traced back to Greek and Roman empires, long before the modern industrial revolution. Markets, during that period, were creating awareness through signs and product descriptions on stone footpaths. In the sixteenth century, a new method evolved when whisky distillers started to ship their products in wooden barrels with the name of the producer etched on the barrels. Thus the product and the maker of each type of whisky were differentiated from the competitor, helping consumers to identify the original product from the cheaper substitutes. Branding received further impetus following the industrial revolution and the evolution of commercialized societies during the eighteenth century. That was the period when city signs were introduced

2 luxury brands versus other brand categories

on products as brand symbol. The method was adopted to indicate the origin of products, which in some cases had associations and perceptions related to the province or country of origin or to the producer itself. The current format of branding has come through different business concepts as companies sought long-term benefits. Luxury brands have an important role to play in the current corporate environment and they are a central part of business strategy.

KEY CONCEPTS FOR LUXURY BRANDS

The luxury consumer. As consumers nowadays are looking for differentiation, they believe that luxury brands are part of the differentiation they are looking for. Consumers behave with a luxury attitude, which is portrayed when “luxury stimuli” is given to them. These luxury consumers are very much different from what they were in the past. They expect to be surprised and pampered, and are always pleased by surprises or when they get what they are asking for from the producer associated with their products. The association comes from the relationships that the producer builds with the consumer and from the way consumers are treated. Thus, we could recognize two segments of luxury consumers. The “traditional” and the “modern” consumer. The first segment is strongly attached to the traditional luxury brands as they knew them from their families. Brand tradition is very important for such families, and it guaranteed the avoidance of the risk of a new purchase. The modern consumers do not ask for brands or luxury products but for full support and service from the brands they buy. They are strongly aware of what they are looking for and are very much attracted by the experience that the brand gives rather than what actually the brand offers. This new generation has many different desires and characteristics compared to the luxury consumers of the past.

Thus, the relationship between the consumers and luxury brands has changed. Consumers are purchasing luxury brands because they think that these brand best fulfill their needs. Also, in some cases, these brands are the solution for a big problem in their everyday lives. Luxury brands help consumers to define what they really

want, who they are, and how best they communicate amongst themselves and their peers. The strong attachment between the consumers and the luxury brands stems from the role of the luxury brands as symbols of personal identity. The modern luxury consumer offers his or her loyalty to luxury brands under the premise of being delivered the best possible, relying on its expectations. This expectation does not have a simple meaning, but has a dual character. It includes both functional and emotional benefits not only for the buyer but also for the users. In general, the symbolic needs are the most important ones as in some cases, consumers might find the functional ones in other brand types. Some of the intangible promises that consumers are getting are the ego of the consumer, the self-image, and self-esteem. The intangible level brings the consumer to a continuous movement from the rational to the irrational, which needs to be fulfilled. The main characteristics of the luxury consumer might be defined as follows:

- The luxury consumer is powerful. Consumers nowadays have more choices and more ways of purchasing the products they desire. Of course, the number of luxury brands has increased when compared to the past.
- The luxury consumer has high expectations and values. Luxury brands offer a variety of products and high standard of services. Consumers would like to understand the way these products are made and in many cases the material used to make the product. Consumers of luxury brands are persistent in their choices, they are strongly individualistic, but also socially disciplined, and they want to know the ethical issues related to the production of the luxury products they are buying.
- The luxury consumer is well traveled and well aware of the products and brand offerings. Luxury consumers nowadays are difficult to be cheated, in terms of product offerings. Consumers know, and are capable of analyzing, the brand or product messages and translate them to their benefit. They are also more informed through trips they undertake very often. They also know when to trade down in some categories of goods when purchasing luxury or other types of

goods. They also expect luxury brands to understand their needs, give them individual attention, interest and customization, which will give them more satisfaction from it. If a luxury brand is not satisfying them, they do not move on to another luxury brand, but engage in a dialog with the producer, building a relationship between the two. Such a relationship leads to strong brand loyalty, which is very important for the luxury brands as well as for the other brand categories.

As consumers have strong relationships with the brand producers, they need to have a continuous dialog between them. The following are the main principles of the dialog:

- luxury brands are synonymous with innovativeness and progress;
- luxury brands must embrace all types of products or services;
- luxury brands must have a clear value proposition related to the needs of current or future consumers;
- luxury brands must be adopted to the current environment;
- luxury brands must never negotiate their status.

Managing luxury brands. Brands are assets to the companies that own them. These assets come in an intangible form, and result in an added value for the company. In 2006, Inter-brand placed a brand value of US\$17.6 billion on Louis Vuitton, making it the most valuable brand in the luxury goods industry and among the 17 most valuable brands in any product category in the world. In addition to the benefits that these brands give to the companies, brands help consumers to identify the source of a product, reducing the risk in their purchases. Luxury brands are very beneficial to consumers because of the functional and emotional needs they satisfy. They can deliver valuable and exceptional promises and create strong brand perceptions. They can reduce the disappointment from other brand categories. The key words for luxury brands are innovativeness and differentiation. Differentiation is part of the

tangible element of the brand, and innovation is interpreted differently by consumers. Thus, luxury brands combine both tangible and intangible aspects. Apart from these elements, in most of the cases, luxury brands have a strong emotional appeal.

How can the luxury brands be differentiated from other brand categories and which is the best way of doing this? The answer is – by enhancing the brand concept, and also by brand and product performance. The brand concept incorporates all the elements that could appeal to the consumers and the market. The brand concept is reflected through the brand name, the country of origin, the logo, and all the elements that are attached to the brand. Luxury fashion brands have a distinct brand concept differentiating them from others, although they share the prestige value. The horse carriage of Hermes logo represents the beginning of a very careful production that will last forever. The color is also unique to the brand and the taglines are in French reinforcing the country of origin of the product. The most visible aspect of a luxury fashion brand concept is the brand name. Usually, the brand names adopted are those of the founders of the company or of major designers of the products they sell.

Adopting a brand name for a luxury good requires careful handling from the marketing managers' point of view. The brand name is the tool that links the product with the market through different associations. Consumers need to easily identify the luxury brand among all the others. Under this consideration, some of the luxury brands, recognizing the symbolic value of the brand name, modify their brand names into more modern names that are more appealing to the new target groups or customers. A brand name for luxury goods needs universality. A luxury brand needs to be known and be remembered globally, even though the use of the product is rare, or the consumers are not aware of the usefulness of the product in their everyday lives.

Brand identity. Brand identity is one of the core elements of the brand and is strongly attached to the way consumers perceive the brand. Positioning is based on brand identity. The way consumers perceive the branded product has to do mostly with brand identity. If the brand

4 luxury brands versus other brand categories

identity is clear then the success of the brand is guaranteed. Luxury brands have a very clear identity which relates the tangible and intangible aspects and the rational and emotional issues all together. The attributes and the identifiable elements of the brand constitute brand identity. The two major dimensions of brand identity are brand image and brand personality. Brand personality is the personality of the brand and has to do with the perceptions of the consumers or how the market perceives the brand. Brand image is the way the brand is seen by the people exposed to the brand communication. The differentiation between brand personality and brand image is sometimes difficult when speaking about luxury brands. Luxury fashion brands have a unique advantage in the brand personality and image development process because consumers perceive them as luxury. That is the reason luxury brands need slogans or characters commonly found in other consumer goods categories to accompany their brand symbols. Luxury brands share brand personality elements like originality classification, reliability and glamor. The levels to which the brands are adopting the above dimensions depend on the producer, the target group, and the market competition. In order to develop brand image and personality, the following five statements are crucial:

1. a holistic development with other brand elements related to the brand;
2. a clear positioning enhanced by the verbal and nonverbal communication the company adopts;
3. clear communication of the brand elements as a whole;
4. consistency over time and through ages and generations;
5. clarity in personality and the image communicated to the public.

Brand value. Brand value is the final outcome of the branding strategies. Brand value is the financial outcome for a company and leads to brand equity. Brand value is important for a company because in some cases it leads the brand being a very strong tangible asset, leading the company to higher levels of performance. Brand

value is not a concept per se; it starts when the product is created and has an infinite end. For the time being, only a valuation method for luxury brands has been created. Companies that want to evaluate luxury brands are using methods created for other brand categories; these methodologies could not be considered appropriate for luxury brands.

THREATS FOR LUXURY BRANDS

Because of their high success, luxury brands meet counterfeiting. The four levels of counterfeiting that are very common nowadays include:

1. A counterfeit product which is the exact copy of the original product. Consumers believe that they are buying the real one or the genuine product.
2. An imitated product which is not identical but similar to the original one.
3. A craftsmen product which is similar to the original but the similarities are not so strong. In most of the cases the craftsmen producing these products have a connection with the brand.
4. A copied product, which is a copy of the original, and most often consumers are aware that it is fake. They are aware that the product is inferior in terms of materials used and way of production, but as they cannot buy the original, they prefer the copied product.

The luxury goods sector battles all the above fake products. These goods are marketed everywhere. These products damage the image of the original products, and, overall, the image of the brand. For the companies producing these products, there is a continuous fear of losing their prestige and facing a big failure of their marketing strategies. In 2003, counterfeit goods market cost New York more than one billion in taxes, an immense weight on the state's economy. Nowadays counterfeiting in fashion goods is very common. Counterfeiting was, and remains, a big problem for luxury industry for centuries. Luxury brands such as Burberry and Louis Vuitton are trying to battle counterfeiting by communication or by approaching the consumer and explaining the problems of using counterfeit

products. Louis Vuitton spends approximately €10–15 million per year for the battle. Part of this budget is given to lobbies, which try to influence governments to protect these products by banning their product or by strengthening their laws. Additionally, the company created an intellectual property bureau. It also employed agents who travel all over the globe in search of counterfeit factories and export orientation reporting them to the local authorities. The company also tries to educate consumers about counterfeited products. Louis Vuitton assists the seizing and destroying of counterfeit materials and finished products.

Managing the world of luxury business is quite fascinating. The development and implementation of effective branding strategies for luxury brands need constant revision and adaptability. Luxury brands have to be always innovative and creative in their marketing strategies. They should clearly deliver a strong message to their audiences. Every luxury brand needs to integrate different brand elements related to the market and to the consumers. There are techniques and tools that need to be used when planning and deciding about luxury brands. Some basic principles need to be adopted when luxury brands have strong and persistent presence in the market.

- Maintain a clear brand personality and identity
- Reinforce when necessary, especially when counterfeiting is prevalent
- Look for what competitors are doing and try to protect your brand
- Branding for luxury brands is quite important when consumers rely on it but also on the company
- Luxury brands are special brands which need special treatment.

customer relationship management and integrated marketing

Edward C. Malthouse and Bobby J. Calder

Customer relationship management, or CRM, includes all interfaces between consumers (or customers) and a company. It covers the interactions or contacts with the consumer, initiated either by the company or by the consumer (*see* CUSTOMER RELATIONSHIP MANAGEMENT). Hence, CRM activities occur when a customer calls a service number or when a current customer is sent an offer for a related product.

CRM is more than a name for these activities. CRM has come to be defined as an *informed approach* to interacting with consumers. CRM implies that the company should base its interaction with consumers on data. If a customer calls, the person answering the call should ideally have access to that customer's history of requests and their resolution. If the company attempts to cross-sell a consumer, the offer should be based on an analysis of that customer's previous purchases. CRM "systems" are thus designed to make interactions with consumers more data based (*see* PRODUCT DESIGN). The goal of CRM, as the name implies, is to turn interactions with consumers into ongoing relationships.

While the goal of CRM is to foster greater intimacy with the customer, there seems to be wide agreement that, in practice, CRM is often very tactical and impersonal. Often companies focus more on the hardware and software systems used in CRM than on the goal of making customer interactions more meaningful. This is even more the case in the United States than in other countries. There is even some indication that interest in CRM has recently cooled (as of the mid-2000s). Although CRM expenditures will no doubt grow in the long term, it increasingly seems that companies and vendors have been driven too much by a tactical IT approach.

From a longer term perspective, some companies are trying to make CRM "more strategic." As pointed out by Rigby and Reichheld, for example, companies have sought to define CRM as "the bundling of customer strategy and processes, supported by relevant software, for the purpose of improving customer loyalty and, eventually, corporate profitability"

(Rigby, Reichheld, and Schefter, 2002). Note the emphasis on CRM as a way of turning strategy into activities.

Along these lines, Bligh and Turk relate CRM to Michael Porter's framework for strategy. Porter stresses that strategy can no longer be approached as mere operational excellence (OE) (Bligh and Turk, 2004). Such excellence is necessary but not sufficient to sustain competitive advantage. Strategy is about either cost leadership or activities that differentiate the firm from competitors. In Porter's terms, it needs to provide a competitive advantage in terms of cost leadership or marketplace differentiation. For example, CRM could be viewed as a way of reducing the total cost of dealing with consumers. By creating relationships with consumers, the company increases its efficiency in dealing with them. The line, however, between cost leadership and mere operational excellence is a fine one.

Thus, the most compelling way of approaching CRM more strategically is through seeking competitive advantage in the marketplace, though this has been relatively neglected in most applications of CRM to date. The big question is how can CRM contribute to competitive advantage in the marketplace? How can it *be* a competitive advantage? The answer is that companies need to connect CRM to the process of designing contacts for subsegments of consumers. The goal is to let these consumers experience the brand in a more individualistic way.

CRM AND SUBSEGMENTATION

Segments are groups distinguished from others in a larger market. By definition, they are receptive to a brand in a way that other consumers are not. A segment may be defined in various ways (e.g., demographically, psychographically, attitudinally, or behaviorally), but it is always a group of consumers who currently – or potentially – value the brand in the same way. Segments share a common overarching receptivity to the brand (Calder and Malthouse, 2003).

On the other hand, *subsegments* are divisions of a basic segment into subgroups. By definition, a brand appeals to all of a market

2 customer relationship management and integrated marketing

segment. But the concept of subsegmentation goes beyond this. It implies that the brand can be further strengthened by building on the appeal of the brand for the entire segment by adding customized contacts. The idea is to customize interaction with the brand in some way for each subsegment. The marketer aims to allow different subsegments to experience the brand in a more individualistic or idiosyncratic way. These contacts are contingent on some unique characteristic of the subsegment's identity. One way of looking at this is that by customizing contacts with the brand to a specific subsegment, the brand can establish a relationship with the consumer.

CRM therefore becomes the key part of a marketing strategy. Relationship marketing is considered one of the highest forms of marketing strategy. Often it has no more substance than advertising that proclaims that the company wants to be the consumer's partner in something. But if implemented through CRM, contacts that really do depend on dealing with different consumers in a way that is contingent on who they are, the strategy can attain much more

substance. At the same time, the brand itself provides leverage in that the brand appeals to the entire segment and is not being changed for each subsegment. This actually raises the possibility of both strategic differentiation and cost leadership.

In summary, the strategic use of CRM is to subsegment one's market in order to create contacts that allow specific subsegments of consumers to make a personal connection to the brand. At the same time, marketers can preserve the cost advantage of otherwise marketing to consumers in the same segment, the same way.

packaging and brand design

Bobby J. Calder and Steven DuPuis

Packaging plays a vital role in the advancement of brands. The package has evolved from being a way of safely transporting products to becoming one of the most important marketing tools for brands. Even the early Greeks marked their bottles with unique symbols to distinguish their maker. Modern day branding, as we know it, began in the early nineteenth century with the iconic packaging of Campbell's, Kellogg, and Quaker. Henry Parsons Cromwell developed the Quaker brand mark, becoming one of the first to create a cohesive marketing program. The packaging, advertising, and promotional elements were all consistently integrated and implemented.

Despite this history, in the recent past, marketers tended to underestimate the importance of packaging. It was considered one of the 4Ps and much less important than other areas of marketing: promotion, pricing, product, and distribution (place). Packaging was either at the end of the list of P's or a small part of the product P. Today, however, the importance of packaging is evermore recognized. It serves as the only form of communication that is seen by 100% of the brand's customers. In today's fragmented media environment, packaging is a critical form of marketing that uses strategic design to identify, inform, differentiate, persuade, and delight consumers to purchase. This has established an industry term, brand design, to describe this valuable marketing function.

WHAT IS BRAND DESIGN?

Branding is an effort to make products more meaningful to consumers. To do this one has to go beyond the product. One must transcend whatever the product is as a physical or objective entity. One must create and convey the meaning of the product so that the consumer's idea of the product is the idea that one wants them to believe. This is a process. It begins with an internal description of the meaning of a brand that is then transformed into something tangible that consumers perceive. If they perceive what the marketer intends, the result is a brand

design. The result is a design in the sense that it fulfills its intended purpose.

The meaning can, of course, be expressed in many ways. It can be expressed verbally through words, names, and descriptive language. Or it can be expressed visually through pictures, symbols, colors, and shape/form. The goal of brand design is to use these verbal and visual devices to convey the meaning of the brand. In turn, consumers will perceive these as cues collectively and use them to make inferences about the brand.

Take a brand like UPS for example. At present, the central brand idea for this package delivery product is one of simplicity, functionality, and basic reliability. The UPS brand is something that one does not have to worry about. It is like a basic service: turn the switch, the lights come on. Send it UPS, the package arrives. The brand design aims to convey this brand idea in a way that the consumer perceives it. The design is based on the verbal and visual cues surrounding the product.

Brand design is different from the marketing communications task of telling the consumer about the brand with advertising messages. The brand design aims to let the consumer perceive the idea. Perception is fast and categorical. It proceeds and influences conscious thinking. The perception is more emotional than rational.

In the UPS brand design, the primary color is brown. What does the consumer perceive? Basic, down-to-earth, grounded. Just the perceptions intended by the brand idea. The design is successful.

The descriptive language features a slogan, "What can brown do for you?" The words are cues. Again the perceptions are routine, basic, and simple.

Visually the brand design uses a symbol in the shape of a brown shield—official, basic, and reliable.

The design, of course, spans uniforms, trucks, and packaging materials. It is also integrated into advertising in the form of an ordinary businessperson explaining how simple it is to use UPS by drawing a basic diagram with a brown marker on a whiteboard.

Brand design is thus the process of representing the brand idea in the reality of the consumer's world. All the consumer has to do is to take in the look and the feel of the product to

2 packaging and brand design

know what it is. Advertising can make use of it and build on it to tell the consumer more about the brand in an informational or emotional way. But the brand design speaks for itself and can be effective even without advertising.

The package of the 4Ps mindset is still there, but it is one of the presenters of the brand design.

BRAND DESIGN VERSUS PRODUCT DESIGN

It is critical that marketers separate brand design from product design. The two are intertwined in the marketplace, but must be addressed differently. With product design, the marketer is concerned with how the product itself is physically experienced. This is likely to be measured in terms of product characteristics, for example, the sweetness of a drink, the sharpness of a picture, the stiffness of an automobile's ride. Most often, measurement is best accomplished with panels of people who are trained to detect and describe these product characteristics and who experience the product in environments that eliminate perceptual cues.

With brand design, however, marketers should try to minimize information about the physical product. It is best to evaluate brand designs with actual consumers. Since the goal is to evaluate perceptual impact, consumers should be exposed very briefly (a few seconds) to the design. It is important that they react in a perceptual mode – fast and automatically. More considered responses tend to obscure actual perceptual responses. One of the worst methods of brand design evaluation is to give consumers in a focus group (or in other types of open-ended interviews) a design and let them comment on it. Such settings are very likely to stimulate people to think about the design in all kinds of ways (including playing design expert) that obscure the design's real perceptual impact.

Even a good brand design can be undermined by a poor product design. In the marketplace, perception and the experience of the product itself come together. It may well be that a strong brand design can succeed even in the face of a weak product design. But this is by no means guaranteed. In the best case, brand design and product design are both optimized separately and come together synergistically in the marketplace.

MARKETERS AND DESIGNERS

Marketers and designers often have different perspectives. Effective brand design requires more than just a division of labor, it requires collaboration too. Brand design is truly a process in which the marketer communicates the brand idea to the designer who translates it into reality. The designer makes the idea, so to speak, come to life. And the marketer evaluates the results based on whether the consumer's perception of the design matches the originating brand idea. Any lack of collaboration can cause a breakdown in the process at any point.

Design for marketing has evolved from its early beginnings as commercial art, visual communication, and graphic design to become a strategic methodology for brand design. This can be seen with the growing use of carefully planned visuals, such as mood boards that convey a brand's meaning, allowing marketers and designers to collectively communicate. Moreover, marketers and designers no longer think of this as a linear process. To some in the marketing community, design is still too often viewed as merely the implementation or execution of a brand strategy. However, in today's visual environment, design has become a vital element in the development of a brand strategy. We now see marketers and designers working together in the early stages of development, from innovation to brand positioning. A company's success is now seen through the collaborative efforts found within the diverse talents of marketers and designers.

Marketers and designers must stay connected in watching for societal changes that may affect consumer behavior. Strategies need to be reviewed and updated through collaborative efforts. Successful product launches and brand repositioning are achieved through strategies that begin with an integrated team approach. One would not enter a basketball game with the team members meeting for the first time on the court. Yet, in the past, we demanded success from designers that joined the team halfway through the marketing program. In the end, realizing and respecting the different talents that designers and marketers bring to the team is the key to collaborative success.

In some companies, design is being elevated as its role is seen as vital to the success and health of the organization. Many companies have begun to build design cultures internally, such as P&G, Apple, and Kraft, to name a few. They have made operational changes to include VPs of design. CEOs as well as marketers are increasingly seeing design as a key driver to increasing sales and ROI, and progressive companies are even giving design a seat in the boardroom.

These companies realize that an increase in competition and commoditization has led to product parity, leaving design and innovation as the only path to differentiation. As Daniel Pink says in his book, *A Whole New Mind*, “it is not enough that a product be reasonably priced and functional, it must also be beautiful, unique, and meaningful.” Many retailers such as Target, Waitrose, Trader Joes, and Apple stores effectively use design as the primary way they influence consumers. Design plays to our emotions, inspiring rational thought by elevating our senses and creating a desire to interact. A study conducted by The University of Rochester School of Medicine found that eliminating emotions made it impossible for people to make decisions. Proof in the marketplace is Karim Rashid’s sculpted trash can, Michael Grave’s houseware line, and Deborah Adler’s innovative packaging for prescription drugs, all successful, once-boring utilitarian items. When consumers are making a buying decision, they put themselves in the picture and evaluate the benefits and emotional risks of that decision. Even price is seen on an emotional level. Within a few seconds, buying decisions are rationalized on the basis of the facts, but the final choice is based on feelings. Humans buy when they trust and feel comfortable; they often justify the facts and buy on emotion. Reality is not perception, but perception is reality.

To stay competitive, companies must search for strategic advantages. Design is a key differentiator within a commodity-driven market place. Even as some companies continue to chase price and value, design and innovation plays an even bigger role in setting brands apart from their competition. Progressive companies look more and more to brand design.

BRAND SYSTEMS

Closely related to the design of individual brands is the design of systems or portfolios of related brands (see BRAND EXTENSIONS AND FLANKER BRANDS). Brand systems must also be approached in terms of creating perceptions, but, in this case, these perceptions define a general core essence or similarity that holds together disparate products. Think of the Virgin brand umbrella, which covers everything from air travel to colas to electricity. Companies increasingly count on taking successful brands into new forms, alternatives, and categories. Thus Kraft has recently taken the Oreo brand from cookies into cakes. This is held together by the core perceptual essence of “fun to eat.” David Aaker, among others, has written about managing such systems of brands (Aaker, 2004).

What permits a brand to become a system or portfolio of products is a brand idea that is broad enough to allow different product versions to be categorized as fitting the idea at a perceptual level. As with a single product, the perceptions expressed by the brand design can facilitate this.

BRAND DESIGN, CONSUMER EXPERIENCES, AND 360 DEGREE MARKETING

Increasingly, any brand must be an experience brand. Product parity and information overload is rampant. Without good brand design to inject life into the brand, this can be very difficult.

From Apple iPhone to Wal-Mart, brand designs serve as a holding device for our thoughts and feelings about things in our lives. They tell us stories that speak to our needs and wants. Their memorable mnemonics trigger cumulative memories and experiences. We look to them for inspiration, guidance, stability, and excitement. Each one comes with a promise and an expected brand experience.

Recently, we have seen a shift to fewer marketing dollars being spent on traditional advertising, largely due to the change in market conditions, media fragmentation, and an overcommunicated society. As a result, marketers place increasing importance on the in-store experience. A recent study by Deloitte Consulting found that 70% of purchasing decisions are made in-store and 68% of purchases

4 packaging and brand design

are impulse buys. This was important enough to have the former CEO Alan Lafley of P&G coin the term *first moment of truth* (the moment when consumers pick up a package). He built a successful corporate strategy around this consumer insight, called *shopper marketing*. This is not limited to just in-store merchandizing. Brand design must play a very significant role.

Retail environments and the products and brands that fill their shelves are seen by millions of consumers each day. Some brands win big in these settings while others lie unnoticed and neglected. This is the battlefield, the theater for brands to thrive or die.

In 1970, there were around 10 000 products on a grocery store shelf. Today, there are over 46 000. However, 50% of the products are not even seen by the average consumer and thus we are faced with an increased need for attention and impact. With all things equal, and with so many competitive choices, an effective brand design can be the tiebreaker in the purchase decision process. Within the retail environment, it is also the only place where brands will be seen with all their competition. So a brand design's effectiveness is critical. Brands and their packages must persuade, educate, and entertain in ways that delight and entice customers. Marketers and designers need to view this area as an opportunity to continually present their brands in new and fresh ways.

Ultimately, brand design speaks to the strategic creation of the customer experience. Each customer touch point or contact is critical to the overall acceptance of the brand idea. Each touch point that a consumer is exposed to defines and establishes his or her impression of a brand. Within these touch points, consumers will judge and assess whether they feel that the experience is authentic and worthy of their involvement. For many brands, brand design is the No.1 touch point with consumers.

There is also the need to keep pace with change. As the competition changes, so do the dynamics of the entire category. Brands are always on the move. As social and cultural views change, so does the visual language that represents these thoughts. The goal for marketers and designers is to respond in ways that keep their brands pure, fresh, authentic, and relevant. Marketers and designers need to look inward, be

intuitive, and ask what has excited us and made us become involved with a product. After all, we are all consumers. Our ability to analyze social, cultural, and visual trends is critical; the skill is utilizing this information through collective collaboration and innovative hypotheses.

Established brands, of course, walk a fine line between embracing such change while not compromising their design equities and core brand idea. When Tropicana removed the orange with the straw from its package, a connection was broken with long-established design equity. Consumers found themselves cut off from their familiar perceptions of the brand. Furthermore, the redesign complicated the shop-ability of the brand, confusing customers further. Scott Young, President, Perception Research Services, states, "to avoid major mistakes, designers need to steer clear of brand hesitation and confusion at the shelf, thus ensuring shop-ability." The key to creating breakthrough at shelf is judging when and how to be disruptive with your brand's design equities.

THE FUTURE

In sum, we believe that "packaging" of the little P variety belongs to the past. The future is brand design. Marketers and designers must work together to bring brands from concept to reality in ways that express the meaning of the brand in verbal and visual ways that the consumer can immediately perceive. For many, if not most, products the marketer cannot wait for advertising to get the brand message across. The consumer must be able to know the brand simply by apprehending it.

the concept of bundling: when the package contains more than its parts

Michael Kamins

INTRODUCTION

The term *bundle* is derived from the fourteenth-century English term *byndel* or *bindan* which means to bind together (Merriam-Webster, 2008). At that time, bundling was a practice in which a young man and young lady slept together in the same bed, usually fully clothed. What may seem strange today was common then as an acceptable form of interaction to allow parties of marriageable age to talk quietly when the day's work had been completed. They seemingly could relax together without the need to sit near the fire to keep warm—in effect they were all “bundled up”. In marketing's use of the term, what is “bundled” are typically products and not people. The modern concept of bundling derives from the economics literature of the 1960s and the issues of tie-in sales where the firm chooses to sell the products together as a bundle and not separately (Guiltan, 1987; Stremersch and Tellis, 2002). In an economic context, bundling has been studied from the perspective of a seller's motivation to bundle (e.g., is it an optimal strategy or not and under what conditions?), as well as consumer welfare and the impact of competition (Burstein, 1960; Stigler, 1961; Adams and Yellen, 1976; Telser, 1979; Schmalensee, 1984).

TYPES OF BUNDLES

Price versus product. From its economic origins, bundling began to expand, developing into a relatively common and effective marketing strategy in which products were combined together into one offering. From the consumer perspective, bundling is based upon the idea that consumers value the grouped package more than the individual items that make up the package and appreciate the resulting simplification of the purchase decision that grouping provides. This strategy is very common, for example, in the software industry (e.g., consider Microsoft's Office which bundles a word processor, spreadsheet, email program, and presentation

software), the cable industry (choice of basic and premium channels at one price), and the fast food industry (McDonald's Value meal includes an entrée, fries, and a drink for a discounted price). Bundling also offers various benefits for the seller inclusive of demand inducement and revenue enhancement. Whether they band together or operate as diversified entities in selling bundled goods, manufacturers benefit from improvements in costs via scale economies. Marketing firms and distributors that use different methods (like franchising, direct selling, and multilevel marketing) also stand to benefit through a faster turnover of inventory. Indeed, some industries can use bundling to effectively compete with foreign competition through the enhancement of product variety and value.

Stremersch and Tellis (2002, p. 56) define the term *bundling* in a marketing context as “the sale of two or more separate products in one package.” These authors refer to both products and services. They further distinguish two different forms of bundling: that termed *price bundling* and a construct described as *product bundling*. In the former case, the separate products are sold at a discount without any attempt to integrate them into a cohesive whole. Such a form of bundling does not in itself create added value to the consumer and hence the maximum price consumers are willing to pay for the bundle (i.e., the “reservation” price), is by definition, equal to the sum of the conditional reservation prices of the separate products that make up the bundle. Therefore, in order to motivate purchase of the bundle, a price discount typically has to be offered. Examples of these types of bundles include purchase of Coca Cola and tickets to Great Adventure Theme Parks, or the bundling of Windows and Explorer by Microsoft, which was a focus of the government's antitrust case against Microsoft in 1998.

Product bundling on the other hand, involves the selling of separate products at any price. Here the combination of products into a bundle provides some segment of consumers with added benefits such that the consumer's reservation price for the entire bundle exceeds that of the individual elements that make up the bundle, and hence a premium could be charged. As Stremersch and Tellis (2002, p. 57) note, a

2 the concept of bundling: when the package contains more than its parts

product bundle can therefore be thought of as having an integral architecture that relates to an underlying characteristic of the grouping (Ulrich and Eppinger, 1995). For example, the Optimum 3D network combines television, on-line and “voice” into one bundle providing the consumer with added convenience and efficiency. Price bundling has been used mainly as a promotional tool, whereas product bundling has been used more strategically since it provides the consumer, if done correctly, with added value.

Bundle Form. Bundles can also be characterized according to their form. One such dichotomy is termed *pure* versus *mixed* (Adams and Yellen, 1976; Stremersch and Tellis, 2002). When using a *pure bundling strategy* the firm is said to sell the products involved only in bundle form and not separately. As noted earlier, in the economics literature this strategy is also known as *tying* (Martin, 1999). It is this area of bundling that has received the most attention from the courts, as consumers have balked at having to purchase another additional item when their goal is to purchase a different item (Stigler, 1968). Clearly, this can be seen as problematic especially if the items contained in the bundle are not offered for sale separately and the consumer really does not want one of the items.

A “mixed” bundling strategy is used when a firm sells the items contained within the bundle separately as well as in bundle form. When this approach is used, it can have significant implications for the value that consumers put on the individual items when sold separately, specifically when one of the items is offered for free (Raghubir, 2004; Kamins, Folkes, and Fedorikhin, 2009). If a firm does not use a bundling strategy, one can describe their approach as “unbundling”. However the use of such nomenclature only makes sense when one compares it to a bundling approach.

Bundle Content. The products that make up the bundle are also of interest from various perspectives. For example, research by Harlam *et al.* (1995) found evidence for the fact that bundles composed of complimentary items led to higher purchase intent than bundles of unrelated products. Interestingly, the authors received

no support for their hypothesis that bundles composed of equally priced goods would have a higher purchase intent than bundles of unequally priced products. The authors believed that if a supplemental item of inconsequential value was included in the bundle, it would be largely ignored and the bundle would be perceived as essentially one product with little value added. Alternatively, if the prices of the items contained in the bundle are close to equal, both products’ prices would be perceived to be relevant as key components of the bundle. However, in the limit, the impact of offering a free item in the bundle has an effect on the attributions that consumers make about the bundle as a whole (Kamins, Folkes, and Fedorikhin, 2009). Specifically, the inclusion of a free item could lead to the perception of value and hence a higher purchase intent, as opposed to the inclusion of an item that is not free but has a low price. Thus bundles can also differ as opposed to whether or not a “freebie” is included.

Finally, a distinction has been made regarding whether or not the items contained in the bundle are the same or different. The former case is known in marketing as *Buy One Get One Free* or (*BOGO*), while the latter is known simply as *multiproduct bundling* (Gaeth *et al.*, 1990). Recent research has combined the notion of “freebie” with the complexity of the bundle offered for sale (i.e., *BOGO* versus *multiproduct bundle*). Extending the work of Raghubir (2004), Kamins, Folkes, and Fedorikhin (2009) found that describing one of the disparate products in the bundle as “free” decreased the price consumers were willing to pay for each product when sold individually. In effect, giving something away for free (i.e., the supplemental item), led consumers to think of the free item in a negative light, that was reflected in a reduced perception of value when the item was sold individually. This finding replicated the results of Raghubir (2004). However, the “freebie” also had a detrimental effect on the focal (higher priced) item in the bundle when it was sold individually. This was explained by the fact that respondents attributed negative characteristics to the focal item (e.g., last season’s offering, slightly flawed), if one had to give something away for free in a bundle to sell it. Interestingly, a “freebie” offer did not influence the

overall price for the bundle of disparate products while it did when the bundle contained identical products or BOGOs.

The differential effect of freebies on perceived value can be explained by the nature of judgment difficulty; that is, price inferences are easier to arrive at for just a single product than for a bundle, as well as for a BOGO than for a bundle of disparate products. Consistent with this explanation, factors that influence judgment difficulty (i.e., the salience of the company's motive for offering the freebie and time pressure to make a judgment) moderated the effects of a free offer on the amount consumers were willing to pay. This research implies that it may be detrimental to use "freebies" if one is using a mixed bundling strategy where the individual items contained within the bundle are sold separately. This is because the individual item may then be devalued. In addition, the seller should be cautious when selling BOGOs since the task is made easier for the consumer to derogate the single product that makes up the bundle.

CONSUMERS' PERCEPTIONS OF BUNDLES AND PROMOTIONAL IMPLICATIONS

A key question to ask in order to investigate this issue is "How are buyers' perceptions of value formed when presented with a promotion involving a bundle?" Specifically, when purchasers are presented with a bundle what strategy is best to use if you emphasize savings, and what is best to use when you emphasize costs? Kahneman and Tversky's prospect theory and Thaler's mental accounting theory are relevant to this issue (Kahneman and Tversky, 1979; Thaler, 1985). Prospect theory deals with how individuals make choices in situations where they have to decide between alternatives that involve risk. The theory proposes that individuals frame outcomes that differ from a reference point either as positive (gains) or negative (losses). Consumers are said to be much more sensitive to losses than they are to gains. Mental accounting theory attempts to describe the process whereby people code, categorize, and evaluate economic outcomes, such that multiple gains are perceived to be more rewarding and multiple losses are more repulsive than, respectively, a single gain (or loss) of the identical amount. This theory

provides support for the "That's Not All Technique," discussed by Burger (1986) and utilized by numerous Television pitchmen inclusive of Ron Popeil and Billy Mays. For example, the statement:

"I'm not going to give you just this cookie cutter. Oh No! That's not all I'm going to give you. For the same price, I'm going to throw in a fine steel spatula. A bargain I hear you say? But wait . . . I'm going to make it even better, with this splendid temperature probe, absolutely free. Now, who wants this wonderful offer now all for only \$9.99?"

Essentially, mental accounting theory suggests that the way a person subjectively frames a transaction in his/her mind will determine the utility he/she will receive or expect from the transaction. According to Thaler (1985, p. 202), "people try to frame outcomes in whatever way makes them happiest," and thinking about adding individual components into a deal for a fixed price is extremely pleasurable because of continual reveal of the additive nature of the deal.

These theories serve to help us determine the most effective way for the seller to present a bundle to the consumer. Consider the following example adapted from Yadav and Monroe (1993). Suppose a given seller can offer a "mixed bundle" of jewelry to the target market as illustrated in Table 1.

Using the example below, the question remains as to what is the consumers' perceived savings associated with buying the bundle? The way the information is presented suggests that there are two different types of savings for the buyer considering the purchase of the jewelry set. First, there are savings in relation to the purchase of the individual items ($\$359 - \$269 + \$199 - \$149 = \$140$). Second, there is savings in relation to the purchase of the bundle ($\$418 - \$319 = \$99$). So, how will the consumer frame the savings in relation to the purchase of the bundle? There are three potential alternatives:

1. The consumer compares the price of the bundle to the total sale price ($\$418 - \319) and arrives at \$99.
2. The consumer considers the savings in relation to both the bundle ($\$418 - \$319 = \$99$) and the individual items taken separately

4 the concept of bundling: when the package contains more than its parts

Table 1 Components of a mixed bundle offer.

| Price If Items Are Bought Separately | | | |
|--------------------------------------|--------------------|-----------------|--------------|
| Item | Regular Price (\$) | Sale Price (\$) | Savings (\$) |
| (A) Malachite necklace | 359 | 269 | 90 |
| (B) Malachite bracelet | 199 | 149 | 50 |
| Total | 558 | 418 | 140 |

OR

Buy the Necklace and Bracelet as a set for \$319, an additional savings of \$99

- $(\$359 - \$269 + \$199 - \$149) = \$90 + \$50 = \$140$ for a grand total of \$239.
3. The consumer simply compares the price of the bundle (\$319) to the respective price of the items before they went on sale (\$558) or $(\$558 - \$319 = \$239)$.

As individuals perceive multiple gains as more rewarding than a single gain, it was not surprising that Yadav and Monroe (1993) found evidence in support of the second frame above in terms of how consumers conceptualize a bundle. Thus when selling a bundle, it is critical for the vendor to clearly indicate the multiple savings that the bundle provides rather than the total savings, possibly by showing individual item discounts and the separate bundle discount. Alternatively, if the focus is on price and not savings, the seller should integrate all price information into a single bundle price rather than a list of separate product prices that make up the bundle, since the rehearsal of individual prices (since they are outlays) is painful. Finally, at some point, attention should be directed toward the relative savings of individual items within the bundle (\$140 in this example) relative to the bundle savings (\$99 in this example) and how the consumer's attributions about the relative size of these two different savings, maps out onto perceptions about the bundle and the items contained within it.

PROMOTIONAL IMPLICATIONS AND FUTURE DIRECTIONS IN BUNDLE RESEARCH

One of the interesting characteristics of bundles is that when the seller uses the multiproduct form of bundling, which product serves as the anchor? This is an important question since if

there is a great disparity in the price of the two items, will the higher priced item, in effect make the lesser price item seem to be of higher quality or will the reverse effect occur? The answer to this question, has important implications for the value of the bundle as a whole and hence the success of the promotion. While Gaeth *et al.* (1990) observed that consumers averaged the performance of separate items in the bundle to judge overall bundle quality (despite a large discrepancy in value between the two products), Drumwright (1992) found no evidence for this averaging process. This implies the dire need for more investigation on this issue.

An interesting perspective related to this issue has been offered by Kamins, Folkes, and Fedorikhin (2009). These authors suggest that a surprising combination of products (e.g., a bundle containing shampoo and a watermelon) is likely to elicit a significant amount of inferences about the bundle because disconfirmation of expectancies seems to stimulate attribution automatically (Wong and Weiner, 1981). This means that a seller's choice of items to bundle together is critical in the sense that discrepant value or characteristics can serve to motivate the consumer to disparage the bundle as well as the items that individually make up the bundle. As Harlam *et al.* (1995) found that items in a bundle, which serve as compliments to each other (as opposed to similar or unrelated products), result in a higher purchase intent.

Importantly, Kamins, Folkes, and Fedorikhin (2009) also found that the seller can manage the attributions that consumers make about bundles by providing favorable motives for why a bundle contains a freebie (e.g., as an anniversary celebration). However, for this approach to be effective, it is important to outline the conditions under

which attributions are elicited. For example, what is the impact on the joint effect of both price and nonprice information on bundle evaluation? When does one form of information take precedence over another and which leads to greater attributions?

Another area of fruitful research would be to examine the effect that various individual difference variables have on the consumer's perception of bundle value. One such variable, namely, the familiarity of subjects with the items in the bundle has been examined by Harlam *et al.* (1995). These authors found that more familiar subjects were more sensitive to price decreases (indicating a higher purchase intent) than less familiar subjects, but that no difference was observed between the two groups for price increases. Likewise, bundles and their various discounts require a significant amount of cognitive processing to be impactful, therefore, as proposed by Johnson, Hermann, and Bauer (1999), the consumer's "need for cognition" should serve as a fruitful individual difference variable when it comes to investigating the relative impact of bundling as a strategy.

Finally, we have seen above that the way in which bundle information is presented affects the frame that consumers use to evaluate the bundle and the items contained within the bundle. Hence there remains a need to examine how various methods of presenting bundle price information are framed, particularly in the case where an individual item contained within a bundle does not offer a price savings (Yadav and Monroe, 1993). Moreover, the bundle literature needs more focus on whether a price savings is more effective when assigned to the focal item as opposed to supplementary item within the bundle or whether this model is underspecified and other factors are more critical (see Janiszewski and Cunha, 2004).

CONCLUSION

Bundling is one of many different sales promotional devices available to sellers. As such, Raghuram, Inman, and Grande (2004) propose that its impact on consumers can be examined from three different perspectives: economic, informational, and affective.

According to these authors, the economic effect of promotion relates to monetary or nonmonetary (time and effort) gain or loss that a consumer promotion provides to the consumer. Thus the "cost" of consumption is viewed from a broader perspective than simply a monetary one. Hence in the case of a bundle, there can clearly be economic benefit, particularly, if the supplemental item is complementary and not necessarily offered for free. Indeed, one of the economic benefits outlined falls under the label of "convenience," which encompasses increased shopping efficiency due to reduced search costs. A bundle of a razor along with razor blades comes to mind.

The informational route communicates direct or informational knowledge derived from exposure to a promotion. In the bundle situation, there are informational benefits if the bundled promotion makes consumers aware of a product that better meets their needs.

However, for a product included as free within a bundle, consumers may discount its value when sold individually, simply because the approach signaled derogatory inferences about the item on behalf of the consumer.

Finally, the affective impact of promotion relate to the feelings and emotions aroused by exposure to the promotion, purchase of the promotion, or having missed the promotion.

For example, the purchase of a BOGO may make the consumer feel like a smart shopper while, at the same time, provide fodder for why the item was placed on "deal" in the first place.

In summation, the resulting impact of a promotion such as a bundle, cannot be simply measured by sales. At the very least, this article should suggest to the reader that many dimensions should be considered before a bundle promotion can be deemed as a failure or a success.

sponsorship and event marketing

Pascale G. Quester

INTRODUCTION

Long considered as one of the many promotional tools available to marketers and brand managers, sponsorship has become one of the most flamboyant expressions of global branding in the later part of the twentieth century. Just as marketers have become aware of the power of associating their brands with key athletes or sports and cultural events, the marketing of such activities has also become highly sophisticated, turning events and other sponsorship properties into unique experiences that could sustain a branding of its own with their core audiences. As a result, sponsorship and event marketing have both developed in the last two to three decades into exceptionally professional and value-added marketing activities.

This article proposes to first define clearly what sponsorship and event marketing entail. It then offers a brief historical review of their development. The literature dealing with the impact of sponsorship and event marketing on consumers is reviewed next. The following section explores the issue of how to manage sponsorship and event marketing, an area which has received relatively little attention from scholars, leading to some strategies to defend sponsors and events' brands against the tactics used by ambush marketers.

The article then discusses the less apparent, but equally unique, opportunities afforded by sponsorship and event marketing and concludes with some predictions concerning the future of these two related but distinct areas of marketing expertise.

DEFINITIONS

Sponsorship refers to a marketing activity that involves investing in a property (e.g., an event, sport or art), with the view of deriving commercial benefits from the association, more particularly in terms of marketing communication, with this property. Sponsorship differs from philanthropy or corporate giving, in that the money invested is expected to deliver a positive financial

return through brand exposure and, ultimately, sales.

Event marketing is the process by which a marketing strategy and a series of marketing activities are planned and implemented around an event, so as to ensure its profitability and commercial success. Event marketing typically involves securing corporate sponsorships as well as maximizing PR opportunities.

While modern commercial sponsorship is a relatively recent occurrence, with a dedicated special interest group of the American Marketing Association created in the mid-90s, sponsorship has existed in one form or another for a very long time. In ancient Rome, for example, it was common practice for returning provincial administrators or army generals to fund extravagant gladiator games to entertain the crowds in the hope of securing election to public office and lucrative official posts. In more recent history, kings and princes lavishly supported poets and musicians so as to cement their reputation as leading and cultured monarchs. So, while the intent of commercial sponsorship is clearly profit-driven, it is important to acknowledge its role in creating goodwill for the sponsors, be it with consumers, business partners, or employees of the firm.

THE GROWTH OF SPONSORSHIP

Long confused with philanthropy or corporate giving, sponsorship has experienced over the last three decades a spectacular growth in terms of marketing expenditures dedicated to acquiring sponsorship rights. Over the same period of time, it has also become a topic of keen interest for academics and practitioners alike. In 2008, the year of the first ever Chinese Olympics Games, record levels of investments in sponsorship activity were recorded with total global sponsorship rights estimated at US\$43.5 billion, an increase of almost 14% over 2007. In the Asian Pacific region, growth was larger in 2008, but from a lower base, with expenditures reaching US\$9.5 billion, up 25% over 2007 (IEG Sponsorship Report, 2008). These figures, however, are but the tip of the sponsorship iceberg. Related marketing activities aimed at leveraging the investment by promoting the

2 sponsorship and event marketing

association with target audience, such as advertising and PR surrounding the sponsored activity or event, are believed to represent three to five times as much as the value of the initial sponsorship right contract (Quester and Thompson, 2001).

In addition to its global and international reach, sponsorship offers a wide and diverse range of possible activities, from the small community-based grassroots sports programs to the largest and most dominant event in the sporting arena, the Olympic Games. Sponsorship can also be undertaken in a variety of contexts, although sports are by far the most popular area of investments, representing nearly 70% of all sponsorship budgets. This compares to only 3% of sponsorship budgets being allocated to arts sponsorship and 9% dedicated to a third party or cause, in what has been termed *cause-related marketing*. More difficult to circumvent and define, broadcast sponsorship, where sponsors invest money in order to “bring” to the audience a specific program, is a hybrid form between sponsorship and advertising, in that the message is as limited as it is in sponsorship but the exposure intensity and repetition are controlled and paid for, by the broadcast sponsor.

Several reasons can be put forward to explain the increased popularity of sponsorship with marketers. First, sponsorship provided a substitute method to achieve brand exposure for products and brands that are increasingly being banned from being advertised (such as tobacco products or alcoholic beverages). However, other products soon followed suit, as brand managers sought more exclusive platforms in order to avoid an increased degree of advertising clutter. In most developed economies, the progressive withdrawal of government funding, coupled with the increasing commercialization of sports and culture, created a context where corporate sponsorship has become a necessary substitute to government funding to deliver sleeker and more expensive entertainment to increasingly demanding audiences.

The conditions were set, therefore, for sponsorship to provide real potential as a communication and positioning medium for both local and global brands. Over the last two decades, sponsorship and event marketing have also grown

in terms of sophistication and strategic significance to become an intrinsic building block for the equity of some brands, in what has been coined *sponsorship-linked marketing* (Cornwell and Weeks, 2005).

THE IMPACT OF SPONSORSHIP ON CONSUMERS

Initially aimed at providing opportunities for brand exposure, sponsorship was first evaluated for its potential impact on consumers' awareness. Many studies have examined the impact of sponsorship on audience's recall and recognition of sponsor brands, revealing surprising levels of inaccuracy, which researchers have first established (Quester, 1997) and then sought to explain (Johar and Pham, 1999). For example, studies have shown that extreme levels of involvement into the event or activity sponsored prevented consumers from registering who the official sponsors were, so that moderate levels of involvement are preferable to either low or high levels of involvement (Walliser, 1993). Moreover, whether the sponsor is the market leader, whether the product carrying the sponsor's brands are related, or whether there was a congruence between the sponsor and the event itself also influenced whether consumers remembered the sponsor's brands accurately (Quester, 1997; Johar and Pham, 1999; Lardinois and Quester, 2001).

Later work has concentrated on evaluating the impact of sponsorship on other consumer responses, and more particularly attitudes. In particular, research has demonstrated that attitude change is predicated on the ability by the sponsor to leverage the association by widely communicating it (Thompson and Speed, 2000; Quester and Thompson, 2001). While there is no precise recipe on how much leverage should be applied to sponsorship, empirical research undertaken in the context of an art festival showed that a company investing one dollar for every dollar invested in acquiring sponsorship rights would derive substantially better results in term of attitudinal change than a sponsor who spent none, or less than one dollar (Quester and Thompson, 2001).

The impact of sponsorship on actual purchase behavior has not been fully established in the

literature, although some studies have examined the value of shares (that is, the probability that investors would buy shares of the sponsors), following sponsorship and naming rights announcements (Cornwell, Roy, and Steinar, 2001). Anecdotal evidence also suggests that sales of specific brands have benefited from prior involvement in congruent sponsorship investments.

Recognizing that awareness and attitudes are primarily cognitive processes, and that watching an event, sport, or art performance potentially engages consumers' emotions, researchers have recently suggested that emotions may play an important role in sponsorship effectiveness. These researchers have consequently called for any evaluation of sponsorship to monitor the affective response consumers have to the event, describing the persuasion process resulting from sponsorship as one of affective transfer (Christensen, 2006). Hence, as with advertising, sponsorship persuasion appears to follow a dual route of persuasion, via a cognitive path when the product is highly congruent with the activity involved (as is the case for engine oil sponsoring Formula One car racing) or via an affective route when the association allows the brand to capture the emotion of the event (as in the case for Coca-Cola's involvement in soccer).

However, while some aspects of sponsorship are comparable to advertising, the message remains eminently unscripted, in that no other message than the fact of the association is communicated to consumers. Hence, it befalls on consumers to make sense of this association and derive the meaning from it, a process assisted by the degree of fit or congruence that exists between the sponsor and the property it chooses to support. Although referred to in the literature under different other names, including fit and relatedness, the construct of congruence is the one that reflects both the degree to which the association is surprising to, or expected by, consumers as well as the degree to which it makes sense and allows them to derive meaning from the association (Fleck and Quester, 2007). For example, the sponsorship of a series of concerts at the Sydney Opera house by a pharmaceutical company would be considered unexpected for most consumers, until such time as they attended the event and received throat lozenges

in the lobby of the opera house. The logical link between cough prevention and the need for a silent audience at a live music performance would then establish a clear and strong meaning which would assist consumers to recall the sponsor, and would lead to favorable attitudes toward that pharmaceutical brand. In cases where congruence is not so obvious, as when there is no such product-event use, or when it is less easy to determine by consumers, research shows that there is an advantage in articulating this to consumers (Cornwell *et al.*, 2006).

Clearly, property and event managers also have a stake in the way consumers respond (or not) to sponsors' unscripted message. For many of them, demonstrating the effectiveness of sponsorship in terms of consumer response is the key to securing further sponsorship agreements or the renewal of current ones. For event marketers, therefore, evaluating and demonstrating the type and magnitude of consumer response is at the core of developing a value proposition that "sells" this event to potential sponsors, as well as assist in the setting of the appropriate price for the sponsorship. Long deemed a mere transaction between two organizations, sponsorship has been more recently considered from a B2B perspective, whereby the sponsorship agreement involves the building of a long-term relationship between sponsor and property, with both brand managers and event marketers working toward mutually beneficial outcomes. This is described in greater detail in the next section.

SPONSORSHIP AND BRAND MANAGEMENT

In a context where government and public funding has steadily decreased while both sports and art events have become increasingly commercialized, both sponsors and properties have become less transaction-orientated and more relationship driven. Indeed, the simultaneous efforts of product and brand managers and of event organizers have been such over the last decade or so that one can now describe sponsorship in terms of brand alliance (Farrelly and Quester, 2005) whereby the brand of the sponsor and that of the event are associated, for the mutual benefit of the two partners, in what can only be deemed a strategic long-term

4 sponsorship and event marketing

marketing relationship. As such, much of the B2B research on relationship marketing should provide some perspective on how to manage sponsorship.

For example, research undertaken in the context of the Australian Football League has demonstrated empirically that the concepts of trust and commitment are just as important in sponsorship relationships as in any other type of B2B relationships. In particular, commitment, as measured by the degree of leveraging investment committed by the sponsor over and above the negotiated sponsorship fee, is a direct antecedent of its intention to renew the contract for a further term. Likewise, the degree of market orientation of both sponsor and event marketer was found to influence both the degree of trust and commitment sponsors associated with a particular sponsorship agreement. Hence, a longer term view, shared goals, and open and transparent communication were all factors that determined how effective a sponsorship was in the perception of a sponsor and in turn, how likely it was that this particular relationship would continue into the future (Farrelly and Quester, 2003).

Sponsorship, however, can also be conceptualized as a much more complex form of cobranding, whereby “sponsorship moves from being a one-off exchange to being a long-term relationship between two or more organizations, and, as a consequence, sponsorship may be repositioned within the cobranded spectrum of the continuum” (Motion, Leitch, and Brodie, 2003). Indeed, research has established the relational nature of sponsorship and highlighted the need for sponsorship agreements to be market- and long-term orientated (Farrelly and Quester, 2005).

Corporate brands adopting such a cobranding approach to their sponsorship include Adidas and New Zealand Rugby Union (NZRU) (Motion, Leitch, and Brodie, 2003). Adidas became the successful contender for the NZRU sponsorship after they offered both money and also the opportunity to move from sponsorship toward building a powerful cobranded relationship that would expose the All Blacks to the global market (Motion, Leitch, and Brodie, 2003). In return, Adidas would gain media exposure and the chance to expand the size

of the global rugby-apparel market (Motion, Leitch, and Brodie, 2003). Importantly, the brand values of the All Blacks were closely related to those of Adidas. Moreover, Adidas’ corporate vision to create the best global sports brand reflected that of the NZRU to present the All Blacks as a leading international sports brand (Motion, Leitch, and Brodie, 2003). Such a long-term strategic commitment between a sponsor and a sponsored property results in a marketing strategy firmly built on long-term sponsorship.

Importantly, research shows that long-term, mutually trusting relationships between the sponsor and the property, the bedrock of any cobranding strategy, may provide some beneficial protection against ambush marketers and other firms seeking to derive benefits from misleadingly claiming an association with the same event. This is because genuine cobranding builds recognition by consumers of the long-term nature of the sponsorship, builds up the legitimacy of both partners, and, in effect, offers a buffer against any “pretenders” (Farrelly and Quester, 2005).

Cobranding provides access to the strategies of cobrand partners and the opportunity for each brand to pursue these strategies with the help and knowledge of an experienced partner brand (Motion, Leitch, and Brodie, 2003). As such, the opportunity to cobrand with a leading firm may represent one of the value-generating features of engaging in large-scale global sponsorship. Leading sports properties, including the International Olympic Committee or French Tennis Open Roland Garros, are purposefully reducing the stable of their sponsors, so as to enable them to work collaboratively over the long term. Furthermore, the literature has established that cobranding is a source of equity not only for product-specific brands, but also for corporate brands and that it provides a chance to dispose of inappropriate or negative values (Motion, Leitch, and Brodie, 2003). The investigation by Motion, Leitch, and Brodie 2003 demonstrated how two brands can move along the continuum from sponsorship to a successful cobranding relationship through the “construction of a unified identity ... that resulted in the formulation of successful linkages” (Motion, Leitch, and Brodie, 2003, p. 1091).

THE THREAT OF AMBUSH MARKETING

As budgets necessary to engage in sponsorship soared and as many of the prominent properties became locked in long-term relationships, many firms have found themselves unable to join in the club and have resorted to a strategy described as *ambush marketing*, whereby nonsponsors attempt to reap the benefit of an association without incurring the expense of negotiating an official agreement. Some of the methods these ambushers use involve saturating the media around the event, often using event-related themes, in order to create the impression that they, too, are in some way involved in an official capacity.

First identified by Sandler and Shani (1989), following the Olympics Games of 1988, ambush marketing refers to the attempt, by sponsors' competitors, to reap the same benefits as the official sponsors, without the preliminary investment in legally acquiring the rights to do so. Ambushers typically associate themselves with the event by appropriating cognate themes and saturating media with their brands in the immediate vicinity of the event (including before or after the television broadcast of the event, sport, or performance).

Sponsors and event marketers often attempt to prevent ambush by taking legal action, suing companies they believe are unduly exploiting an association with an event or activity to which they have not contributed and with which they are not, therefore, entitled to claim any legitimate link. However, legal protections appear relatively ineffective, as evidenced by the fact that during the 2008 Beijing Games, an ambusher, diary company Mingliu, achieved higher recognition scores than Coca-Cola, one of the top global sponsors for the event. Mingliu was successful simply by using saturation media buying, and using high-profile athletes as their brand endorsers. A better strategy would appear to involve the disclosure to consumers of ambushers' activities as research has shown this to not only erode the brand equity of the ambushers but also to bolster the brand legitimacy and credibility of the rightful sponsors (Mazodier, Quester and Chandon, 2010).

OTHER BENEFITS OF SPONSORSHIP

There are other aspects of sponsorship that appear to have been neglected. These are less frequently cited in the literature and yet they need to be empirically examined by sponsorship scholars. For example, while there is recognition in the literature that sponsors enjoy greater degrees of goodwill from consumers than do advertisers, there is little research exploring the potential of sponsorship to contribute to Corporate Social Responsibility profile, which in turn may also favorably influence both attitudes and purchase behavior on the part of consumers increasingly demanding ethical practices from business organizations.

The potential value of sponsorship in relation to internal marketing and human resource management has also been mentioned in the literature but remains unreported in the extant research, despite anecdotal evidence and case studies demonstrating that sponsorship can be successfully leveraged to bond staff and motivate sales people or service providers. For example, one of the greatest values derived by Credit Lyonnais, the French bank which sponsors the world famous cycling event Tour de France, is that the race stops at the end of every leg into a town or city where there is a Credit Lyonnais branch, giving the bank manager and their staff ample opportunity for hospitality, key client reward programs, and staff volunteering. At Credit Lyonnais, the summer months are dedicated to the running and following of the race, and this helps both in terms of staff recruitment and retention (Farrelly and Quester, 2005).

THE FUTURE OF SPONSORSHIP

The threat of ambush marketing, coupled with the global financial crisis of 2008–2009, has led experts to conjecture that 2008, the year of Beijing Olympics, may well have represented the high watermark in sponsorship expenditures, not the least because global properties are rare, but also because the layering of many levels of sponsorship (athlete, leagues, events, as well as the television broadcast of part of the event) can lead to such complex agreements as to induce the sort of clutter which sponsorship was supposed to avoid in the first place.

An additional threat is the recognized lack of control sponsors enjoy in relation to the image of the property they support. The chronic doping scandals surrounding the Tour de France, for example, are a predicament for the top sponsor of over 50 years, Credit Lyonnais. In the light of repeated instances of high level cheating, is a banking institution, which aims to project an image of trust and reliability, well advised to remain associated with such a high-profile event? At the same time, can it walk away from an event it has literally nurtured and been associated with for over 50 years, and which delivers such excitement to a large network of its bank branches across the national territory?

electronic public relations

Anastasios P. Panopoulos

INTRODUCTION

Internet as a communication medium overcomes the constraints of time and place, enabling the creation and maintenance of powerful relations between communicating parties. The lack of control, the decentralized structure, the open and public nature, the interactivity and interdependency between users are only few of the characteristics that contribute to the wide use of this medium. New online applications and functions, such as social networks, have brought revolutionary changes in the practice of public relations, creating innovative and more efficient ways in the invention, diffusion, storage and recovery of messages, thus altering the traditional communication patterns between organizations and stakeholder publics. Public relations practitioners are becoming increasingly involved in electronic public relations activities such as the launch of web sites, the monitoring of blogs and social networks, the support of e-voting activities, the creation of e-mails and e-newsletters, and so on. While in the past, organizations were identified as the source of information, controlling and directing the flow toward the stakeholder publics, a balance between the communicating parties has been established with the use of the Internet, since, in many occasions, the communication initiative now is undertaken by empowered Internet users (Ihator, 1999). Furthermore, the need for intermediaries or gatekeepers when trying to approach stakeholders is limited in an Internet context, in contrast to what is happening in the real world. According to Kent, Taylor, and White (2003) when it comes to electronic public relations the two-way symmetrical model can be seen as the process, dialogue as the product, and the Internet as the environment that makes it possible to happen. That is why we can argue that the two-way symmetrical communication model proposed by Grunig and Hunt (1984) has found its ideal communication channel since true dialogue between stakeholders can now take place. Furthermore, the Internet can be characterized as the first communication channel

suitable for the transmission of both mass and personalized messages at the same time. For example, web sites as public relations tools can be used to disseminate symbolic content not only to large heterogeneous and geographically isolated audiences – mass communication – but they can also be used concurrently to build one-to-one relationships through the use of interactivity and customization – one-to-one communication. Web 2.0 technologies, in general, elevate the role of the Internet as a public relations medium, creating the need for a more effective strategic approach by public relations practitioners.

Paraphrasing Darwin's famous conclusion, public relations practitioners have to adapt to this new digital environment, as otherwise they face extinction. Traditional public relations activities are simply not enough, since a number of people choose to communicate only through the Internet. However, this does not mean in any way that the value and importance of off-line public relations is reduced. On the contrary, it stresses the need for a close synergy between actions taking place online and off-line. The two key elements for a successful public relations strategy in the new digital era are compatibility and continuation between traditional and electronic public relations. Public relations campaigns should be carefully redesigned to incorporate physical as well as digital elements. In this way, relations that already exist in the real world will be expanded and strengthened in the digital environment, while the overall effectiveness of public relations programs will be maximized.

The necessity for a successful integration of online and off-line public relations activities forces public relations practitioners to acquire new skills and competencies. Most public relations practitioners have no information technology background and, as a result, electronic communication is left to information technology departments with poor results. That is why public relations practitioners have to be transformed to empowered Internet users along with their professional public relations knowledge and expertise. In order for them to acquire some basic knowledge about information technology, training on internet applications and programming is required. Even when this is not the case, public relations practitioners should

always participate in the planning, designing, and monitoring of the digital environment leaving only the execution to the information technology departments.

The lack of continuous evaluation and the difficulty to define measurable goals for electronic public relations are two main obstacles that undermine their perceived effectiveness and their strategic role. In order to evaluate the real value and contribution of the Internet to the total outcome of public relations in an organization, specific measurable objectives aligned to the organizations' public relations strategy must have been set prior to the evaluation (Institute for Public Relations, 2001). Although different measurement techniques exist, the evaluation of online activities remains an unknown term for most public relations practitioners. Electronic public relations' effectiveness can be measured either at a public relations program level (preparation-implementation stages) or at a communication channel level (impact stage). A combination of the previous two levels in terms of economic value, web attendance, time allocation, requests of information, and so on, can reveal valuable information about online public relations activities. Various reasons, such as the lack of specialized personnel, resources, and methodology, are given by public relations practitioners to justify their aversion toward evaluation. However, none of the above is as significant as the results of the evaluation process itself.

There is no doubt that virtual worlds are becoming increasingly sophisticated, enabling organizations and stakeholders to actually step into and directly participate in a dialogic relational approach (Messinger *et al.*, 2009). Web 2.0 technologies enable a shift from the web as a passive information highway to the web as a dynamic platform for the exchange of real communication and experiences, since participation, self-expression, dialogue, and creation and maintenance of relationships within virtual communities is now allowed (Pfeil, Arjan, and Zaphiris, 2009; Wilson, 2006). Future developments will allow a further communication empowerment, enabling public relations practitioners to come even closer to larger groups of stakeholder publics in more effective ways. This article is organized as follows: electronic public

relations principles are first described; in the next section, an analysis of effectiveness of electronic public relations is offered, and in the final section, the future of electronic public relations is discussed.

ELECTRONIC PUBLIC RELATIONS PRINCIPLES

The low cost for launching web public relations activities, the ease of implementation, the establishment of constant communication, and the attraction of a global audience are tempting arguments in favor of the adoption of electronic public relations for every organization. In addition to the aforementioned motives, the rush to secure an Internet presence along with the high competitive digital environment, has led organizations to adopt the Internet as a business panacea without first defining a clear strategic plan. However, web presence is simply not enough, since regular updating of the content of web pages and monitoring of the web environment are necessary actions, the hidden cost of which must be taken into consideration.

Broom, Casey, and Ritchey (1997) suggested that relationship formation and maintenance involve a process of mutual adaptation and contingent responses between parties. According to Thomlison (2000), *effective relationship management* is defined as the development, maintenance, growth, and nurturing of mutually beneficial relationships between organizations and their significant publics and, in order for these relationships to thrive, true dialogue must exist. The web incorporates text, sound, image, movement and the potential for real-time interaction, all in one package (Kent and Taylor, 2002). The element of real-time interaction differentiates the web from other communication channels such as television, newspapers, radio, and so on, where people behave in a passive way, without the ability to respond to messages or even to contribute to a feedback procedure. Through the commitment of organizational resources and training, the web can function dialogically rather than monologically (Kent and Taylor, 2002). As a result, two-way symmetrical communication is emerging as an important applied framework, as the practice of public relations moves toward a relational digital approach. Taylor, Kent, and

White (2001) managed to define the creation and maintenance of electronic relationships in the digital age, through the elevation of web sites as public relations tools. More specifically, they suggested that every web site, in order to promote dialogue and enhance relationships with the stakeholder publics should incorporate five dialogic principles coded as follows: usefulness of information, ease of use, conservation of users, generation of return users, and a dialogic loop. A sixth dialogic principle, coded as *web attractiveness* was added in the initial definition as shown below (Taylor, Kent, and White, 2001, p. 268):

Dialogue first involves attraction (**web attractiveness**), whereby individuals or groups desire to interact (**usefulness of information**); for relationships to develop interactions must occur (**ease of use**); for relationships to grow dialogue must occur (**conservation of users**); and for relationships to thrive, maintenance and satisfactory interactions must occur (**generation of return users and dialogic loops**).

In this context, the public relations' dialogic principles can be expanded in order to be applied to any Internet application or activity performed by public relations practitioners. As a result, it is useful to analyze each dialogic principle under a public relations perspective (Taylor, Kent, and White, 2001).

Web Attractiveness. The beginning of every dialogic procedure stems from a certain attraction/need pushing both parties to communicate. It is the desire to exchange views with certain people that leads every one of us to enter a dialogic procedure in the physical world. Public relations practitioners have to boost that initial need in order to establish a continuous dialogue with all the stakeholder public. The projection of a digital corporate identity through the use of organizational elements such as the emblem/logo, the colors, photographs, and historic archives can improve the awareness of the organization's web activities attracting digital visitors. The combination of awareness and attractiveness in a digital environment is crucial since users are constantly bombarded with information/activities and they make decisions in just few seconds.

Usefulness of Information. The Internet has been named as the *information highway* since it offers quick and easy retrieval of any type of information. In fact, Internet users are bombarded everyday with information that they choose, voluntarily or even unconsciously, to absorb or to ignore. Online communications aim to convey information as well as relate to people. The usefulness of information is the criterion that is used by users in order to decide which information is of value. The essence of dialogue is the exchange of information between the participating parties; this information must be of interest for either side in order for the dialogic process to continue. Especially when a crisis is encountered, web activities, such as the update of the organization's web site, can provide continuous and timely information, attracting the interest of the stakeholder public.

Ease of use. Perceived ease of use can be seen as complementary to web attractiveness when it comes to first impressions. The use of the Internet for public relations purposes can be seen as an innovation, and, as a result, the reduction of technological complexity will help the adoption by the stakeholder publics. Efficiency, speed, and compatibility with the technological infrastructure available to the average user are crucial elements that enable the creation of user-friendly applications. Usability tests can provide a framework for the evaluation of web applications in order to secure a minimum level of ease of use that will enable the evolution of the dialogic procedure.

Conservation of users. The variety of options that every user has, combined with time restrictions of everyday life makes it hard to establish a long relationship in a digital environment. Usually, organizations and users are confined to the exchange of instant messages in an effort to communicate effectively, but in this way relationships can only be established while the maintenance and the quality of the relations is insecure. Relationship building and dialogue need time in order to flourish and prosper either in the physical environment or in the digital one. If organizations do not manage to provide a quality time framework when contacting their

stakeholder publics in a digital environment, the latter eventually will consider other choices.

Generation of return users. The principle of conservation of users should be aligned with the principle of generation of return users leading to the creation and maintenance of strong relationships. Users through repeated visits to older established web sites “prove” their digital relations with them. Public relations practitioners have to multiply the interactions with stakeholder publics in an effort to remind and cultivate relations with them. This is easier with the use of the Internet compared to other mediums, since it is possible to communicate with a low cost regardless of time or geographical barriers.

Dialogic loop. Interactivity and feedback procedures mark the passage from one-way communication to a fully dialogic one, enabling two-way symmetrical communication between organizations and stakeholder publics. Action from one of the two parties in the communication process and reaction from the other is a sign of dialogic behavior, creating a loop. Several applications like social networks, chat rooms, forums, and so on, support the creation of a dialogic loop attracting a high number of users.

Although public relations practitioners incorporate some elements related to the dialogic principles described above, through the use of technological applications, the lack of a dialogic orientation and their failure to apply a relational philosophy restrict the effectiveness of their digital actions. The main objective of electronic public relations is to create and maintain relations with different stakeholder publics in the digital world complementing activities and actions taking place at the same time in the physical world. As a result, every strategic plan adopted for electronic use should be aligned to the one created for the physical world, both projecting the overall public relations orientation of the organization. A dialogic philosophy could serve equally well both electronic and physical environments, allowing a continuous interaction through which a strong bond is created with the stakeholder publics.

ELECTRONIC PUBLIC RELATIONS EFFECTIVENESS

The Institute for Public Relations (2001) recognizes the research function of effectiveness as every planned research action focusing in measuring, with the use of qualitative and quantitative variables, of the relative effectiveness of a program, strategy, or action, compared to predetermined goals. The evaluation of a web action/program should be constant and recurring in order to form a key success factor in an electronic public relations program (Cutlip, Center and Broom, 2000). It is obvious that the avoidance of evaluation is not an option. The measurement of effectiveness of a web action/program is a crucial function that can lead to the improvement of the web action/program and to the disclosure of potential errors, while, at the same time, it can be used as a continuous evaluation instrument. However, according to several studies, the initial approach of public relations' practitioners when designing web applications is confined to a trial-error basis without previous research. This approach can be extremely dangerous, since when stakeholder publics are not satisfied by the function or the content of a web action/program, they will easily turn to other Internet entities, rendering their return to their initial choice a difficult task. Results from usability studies reveal that stakeholder public can trace the information they are looking over the web in a relative small percentage even when they have access to the web page they want (Hallahan, 2001). As a result, evaluation and traffic analysis with the use of the Internet should be constant, extensive, tied with public relations objectives, and, above all, it should be conducted by the public relations departments.

Sometimes, even the web action/program evaluated can be used as a survey instrument through the creation of electronic questionnaires, the use of software metrics, or the performance of usability tests. Online web surveys are encouraged because of the low cost and the relatively high speed they offer. Today valuable online tools such as Google analytics (<http://www.google.com/analytics/index.html>), WebTrends analytics (<http://www.webtrends.com>), Shiny-stat analytics (<http://www.shinystat.com>), De-

epmetrix analytics (<http://www.deepmetrix.com>), and Awstats analytics (<http://www.awstats.sourceforge.net>), are available to public relations practitioners to help them gather information about their online activities. Information about the number of the web pages that a certain user viewed, the time spent on each, the web pages that used in order to come to and leave a web site, the user's perceptions and attitudes toward the web site, the archives that were downloaded, and so on, are only few of the valuable insights that these programs can offer to public relations practitioners.

The oldest and most frequent way of measuring the amount of traffic that an Internet application generates is through the number of hits that it concentrates (Holtz, 1999). Every visit to a web site is considered as a new hit, leading to the increase of the hit counter. This is an easy and simple way to monitor traffic in every web application without the active participation of the user. Furthermore, by recording the objects that the user chooses to hit, useful information about the function and user behavior toward the application would be revealed. However, there are certain reliability issues, since it is impossible to secure the uniqueness of the visitor or the hit. The reason for that is because each distinct visitor's action is recorded by the counter as a new hit increasing the total number of hits. For example, when a user is visiting the internal web pages of a web site or is coming back to the web site with the function of the back button, more than one hit is registered in the counter, creating a deceiving image of the number of visitors. This problem is even bigger if we take into account that in many organizations the web site is used as the home page or the initial web page when employees connect to the Internet.

As an alternative solution, the measurement of unique visitors in a web site has been proposed. This technique is based on the fact that a unique IP address is assigned to each computer in order to gain access to the Internet. As a result, if this unique IP address is recorded when a user is visiting a web site then we will know the exact number of the real unique visitors over a certain period of time. However, even with that approach, several issues of extreme importance

for the public relations field remains unexplored. The number of visitors does not reveal any information about the usability of the web site, the information content, the conservation of visitors, or the capability to enhance dialogue through the web site. Separate measurement techniques can be used to address the previous variables like the monitoring of user behavior or the record of his/her actions. Finally, the association of electronic public relations objectives with economic values and the estimation of the bottom-line contribution to the overall economic result of the organization can also serve as a measurable indicator of effectiveness.

Unfortunately, many organizations focus only on recording instant impacts for a small period of time, forgetting that the main objective of the Internet as a public relations medium is not one-time communication, but the creation and maintenance of long-term dialogic relations. That is why multiple measurement techniques should be combined in an effort to evaluate and understand better the perceptions and attitudes of the users toward web sites (Holtz, 1999; Institute for Public Relations, 2001). Public relations practitioners are responsible for the determination of the variables that will be used in such combinations of techniques.

FUTURE OF ELECTRONIC PUBLIC RELATIONS

Future developments in the field of electronic public relations will be determined by the evolution of information technology and the adoption of it by public relations practitioners. But in order for this to happen either in the physical or the digital world, time is needed. Already Web 2.0 technologies such as multi-user interaction, 3-D animation, open objective environments, and user-generated contents, audio and video transmission, blogging, instant messages, and chat have deeply affected the practice of public relations over the Internet giving a taste of what is going to follow. Internet users and as a result stakeholder publics are gaining more control day by day over their communication with organizations since new applications are even more user friendly and provide new capabilities. Social-networking web sites such as Facebook, MySpace, YouTube, and LinkedIn, and games of virtual worlds

like Second Life have facilitated a greater freedom and realism to online communications. Public relations practitioners and organizations have made small steps in this direction by monitoring and creating profiles in an effort to exploit the power of electronic social networks in creating and maintaining relations. These online environs bring together most Web 2.0 technologies in simple, though highly usable, ways for people who have little to no technical expertise allowing them both content sharing and socializing (Messinger *et al.*, 2009). Public relations oriented blogs and activities that build and maintain social capital (social support, integration, cohesion among stakeholders) in a Web 2.0 environment have promoted these sites as relationship-building tools (Dugan *et al.*, 2008).

It is clear that the challenge for public relations practitioners will be to redesign their approach concerning relationship development with their stakeholders because of Web 2.0 applications. But before doing so, they must be empowered in terms of information technology in order to cope with the digital nature of their duties. Moreover, they have to find ways to secure a continuum and compatibility between public relations activities in the physical and in the digital world. Organizations and public relations practitioners that choose to ignore the electronic dimension of public relations as described earlier will have to struggle to survive in the new, rising, digital era.

attitude – behavior consistency

William E. Baker

INTRODUCTION

In this article, a brand attitude is defined as a “deliberately formed brand evaluation.” It is both conscious and cognitive; it is not free-floating affect (Fazio, 1986). This definition assumes that attitudes are formed through a conscious cognitive process; they are products of deliberate expressions of summary evaluations. The source of the attitude may be “hot” affective responses (e.g., a strong emotional response) or “cold” information (e.g., quality cues, specific performance information). Besides distinguishing a brand attitude from a simple emotional response, this definition also recognizes and conforms to the methodological realities of attitude measurement. Whenever an attitude is measured, that measurement, by its nature, forces a cognitive component and deliberate expression, whether it existed prior to the measurement or not.

Brand attitudes play a central role in models of consumer behavior and models of advertising effects. Theoretically, often-studied and emulated approaches such as the classic hierarchy of effects (Lavidge and Steiner, 1961; McQuire, 1978), the Fishbein model (Fishbein, 1967), the Theory of Reasoned Action (Fishbein and Ajzen, 1975) and the Elaboration Likelihood Model (Petty and Cacioppo, 1981) focus on the process of changing or modifying brand (or object) attitudes. Methodologically, the vast majority of communication effects research relies on assessments of brand attitudes to test the persuasive impact of independent variables. More than 40 years after many attitude-based models of communication effects were developed, it remains fair to say that an explicit (i.e., theoretical) or implicit (i.e., methodological) assumption of most models of communication effects is that persuasion effects, and more specifically brand choice decisions, are mediated by brand attitudes. This presumption is reflected by the absence of research on the direct effects of information, marketing communications or otherwise, on brand choice. For example, 14% of 231

empirical advertising studies published in major marketing, advertising, and consumer behavior journals from 1990 to 1997 used brand choice as a dependent variable (McQuarrie, 1998). The rest either assumed the external validity of the brand attitude–brand choice relationship or were not concerned with it.

When studying attitude–behavior consistency in a marketing setting, it is important to recognize that there is a fundamental difference between the domain of social psychology, in which most attitude theory has been developed, and the domain of marketing. In social psychology, researchers are typically interested in studying people’s attitudes and behaviors toward single issues, causes, or people. They are not, as in marketing, being asked to make a choice among several product alternatives. Also inherent in this distinction is the need to recognize that there are often significant differences between the environment in which attitudes are formed and the environment in which brand choices are made. These differences diminish the relevance of attitudes in choice contexts. Finally, it is questionable whether stable brand attitudes naturally exist in many product categories (Lastovicka and Bonfield, 1982). There are situations in which brand attitudes can be reliable predictors of brand choice; there are also many situations in which they cannot be expected to be reliable predictors. The purpose of this article is to discuss the factors that influence attitude–behavior consistency in marketing settings.

DO STABLE BRAND ATTITUDES TYPICALLY EXIST?

Brand attitudes cannot mediate behavior unless they exist. Most communication effects modelers assume that their questionnaires measure stable brand attitudes in consumer memory. This, however, may not be the case. Lastovicka and Bonfield (1982) argue that people are likely to store firm attitudes toward social issues, but not typically toward branded products. As a result, responses to attribute belief and importance scales in survey research may often be misleading and reflect temporary tendencies, created on the spur of the moment, simply because a question was asked (see also Feldman

2 attitude – behavior consistency

and Lynch, 1988). They further asserted that minor choice behavior can be best explained through principles of behavioral learning theory because low involvement decisions, which most brand purchases are thought to be, are unlikely to be governed by specific attribute beliefs.

According to functional theory (Katz, 1960), in order for attitudes to be held toward a given object, the object must be related to the concept of self, linked to an individual's important values, relevant to an important social group and perceived to give differential need satisfaction relative to other related objects. Using these criteria, it may be argued that consumers are unlikely to hold enduring attitudes toward brands in a great many product categories. The final criterion above adds particular insight into the problem of attitude development for many classes of branded products. It implies that consumers may have stable attitudes toward product categories (e.g., peanut butter, paper napkins), but not toward specific brands within categories (e.g., Skippy vs Peter Pan peanut butter). The lack of perceived interbrand differences in many product categories minimizes the potential for differential need satisfaction among brand alternatives within the product class (i.e., ketchup, paper towels, salt, etc.) and thus minimize the probability that brand attitudes can discriminate between alternatives (Baker, 2001).

People acquire denotative meaning about objects and issues, but evaluative and connotative meaning does not follow unless the brand carries significant personal importance. If one takes the position that most brands do not carry significant personal importance, it follows that consumers are likely to acquire knowledge of a brand that allows them to identify (e.g., "Crest is a brand of toothpaste") and describe it ("It's made by Proctor and Gamble." "It's the number one brand." "It has fluoride."), but not necessarily to evaluate ("It's an excellent brand." "It's the best brand.") or prefer it ("I'm going to buy it next time I need toothpaste."). Emotive and primitive evaluative responses, such as those postulated to be created by advertising, may result in purchase behavior, but do not necessarily lead to cognitively based attitudes. For example, repeated exposure to the brand name and package can lead to exposure-effect-induced purchase (Zajonc,

1980), and emotional associations "conditioned" to the brand by advertising can motivate buying (Baker, 1999), as can the operant effects of price discounting (Nord and Peter, 1980). All of these effects, however, neither require belief formation or attitude formation prior to purchase or after purchase.

BRAND ATTITUDE ACCESSIBILITY

Assuming that brand attitudes are held in a given product category, the attitude must still be accessed before it can influence brand choice (Biehal and Chakravarti, 1986; Fazio, 1986; Kisielius and Sternthal, 1984). This is no trivial matter. People may not retrieve their attitude toward a stimulus before they act. There is no guarantee that there is anything but the weakest of links between the representation of the object and the representation of the attitude in memory (Bargh, 1984; Fazio, Powell, and Herr, 1983).

The likelihood that an advertising-generated brand attitude or any other attitude will mediate choice is a function of its salience at the time a decision is made. A primary mediator of attitude accessibility is repeated attitudinal expression (Fazio, 1986). In one series of experiments, attitude accessibility was demonstrated to be a direct function of the number of times subjects were asked to verbalize an existing object attitude (Fazio *et al.*, 1982). Accessibility was measured using a response latency measure. In subsequent experiments, Fazio found support for the potential of repeated attitudinal expression to lead to the spontaneous activation of attitudes when the attitude object is encountered (Fazio, Powell, and Williams, 1989).

However, experiments by Fazio and Herr (1984) demonstrated that even highly accessible attitudes do not necessarily directly or indirectly (e.g., bias consumer decision processes) mediate evaluation. In one experiment, subjects were told they were about to read a legal case concerning affirmative action. In a 2×2 design, half the subjects were asked to prepare to reach a verdict as they read the case; half were told to memorize all the factual details, but were not asked to reach a verdict. Also, half the subjects were asked to review their personal attitudes toward affirmative action prior to reading the

case, and half were not. Attitudes toward affirmative action correlated strongly to the verdict only in the cell in which prior attitudes were rehearsed and subjects were asked to prepare to reach a verdict. In the memory condition, attitude-behavior correlations were low regardless of attitude salience. Apparently, subjects found the specific information more relevant to their decision than their attitudes on affirmative action. The findings suggest that conscious or subconscious attitudinal mediation of behavior is not a necessary outcome of attitude salience during the decision process. This finding leads to the issue of attitude relevance (Baker, 2001) and diagnosticity (Feldman and Lynch, 1988).

BRAND ATTITUDE RELEVANCE

Even if consumers hold brand attitudes in a product class and even if they are highly accessible in memory, there is still no guarantee that they will mediate choice at the brand response occasion. The question thus remains, when will attitudes formed at time A mediate choice at time B? Assuming that the conditions above are met, evidence indicates that the answer is when the attitude formed at time A is more relevant, that is, more diagnostic than other salient information at time B.

Much of the available research on the effects of prior judgments and attribute information on evaluation or choice is not designed in such a manner that it can specifically address the above question. A large body of evidence demonstrates that memory-based judgments can dominate the evaluative implications of recalled attribute information on subsequent evaluation (Dreben, Fiske, and Hastie, 1979; Lichtenstein and Srull, 1985; Lingle and Ostrom, 1979). An equally large body of evidence reveals a dominance of attribute information over previously formed judgments (Biehal and Chakravarti, 1986; Reyes, Thompson, and Bower, 1980). The research successfully demonstrates effects of judgment and effects of attribute information, but does not specify clear boundary conditions for these effects other than accessibility and does not offer a theoretical framework to explain or predict when each effect is likely to occur.

Feldman and Lynch (1988) built a framework that is able to reconcile much of the conflicting

evidence in the literature. In the context of brand choice, Feldman and Lynch propose that the likelihood that any cognition about a brand, whether generated by marketing communications, personal experience, or word of mouth, will be used to choose that brand is a function of three factors: the accessibility of the input in memory, the accessibility of alternative brand cognitions in memory, and the relative diagnosticities of the inputs.

Brand attitudes that are the output of deliberately formed summary evaluations (i.e., cognitive elaboration) are likely to have an accessibility advantage in memory over more specific brand information because they are likely to be more efficiently stored in brand memory (Alba and Hutchinson, 1987; Wright, 1980). For this reason, they are more likely to become the product of automatic processing (Bargh, 1984) and less likely to become the victim of output interference (Alba and Chattopadhyay, 1985; Hoch, 1984). A simple judgment referral heuristic, that is, the use of an attitude to guide choice behavior, is also a convenient and simple way to make decisions (Bettman, Johnson, and Payne, 1991). *Ceteris paribus*, this gives attitudes an advantage over other more specific information. In Lichtenstein and Srull (1985), both attribute information and prior judgments were given an equal chance of mediating evaluation. In this scenario, judgments formed at time A were accessed and used in favor of the attribute information at time B. However, there was no reason for subjects to make the effort to use attribute information in their evaluation at time B. The evaluation environment was exactly the same at time A and time B; there were no brands, no new brand information, no changes in the purported usage occasion, and so on. The likelihood that a previously formed judgment will be at least as relevant and at least as diagnostic as other accessible information is a function of the similarity between the context in which the attitude was formed and the context in which the choice is made. In reality, unless attitudes are formed at the time of choice, there will almost always be differences.

A CHANGE IN CONTEXT BETWEEN ATTITUDE FORMATION AND BRAND CHOICE

The assertion that brand attitudes measured at time A can reliably predict behavior at time B requires that two key assumptions be accepted. First, one must assume that the attitude formation process and the brand choice process are identical. The pool of information and the rules used to transform this information into evaluations must be identical for the outcomes to be reliably identical. Second, one must assume that the pool of available information, the accessibility and relevance of this information, and the motivation to use that information are unchanged from time A to time B. Evidence suggests that the validity of these two assumptions is highly questionable (Baker and Lutz, 1988).

Bettman (1979) demonstrated that many identified choice-based strategies such as lexicographic, conjunctive, and elimination by aspects do not require an overall evaluation of brand alternatives during the choice process, but rather only evaluation or recognition of specific performance attributes or quality cues. Other research affirms the position that different informational sets and evaluation strategies appear to drive attitude formation and choice decisions (Johnson and Russo, 1984; Bettman and Zins, 1977). If this is true, there is no reason to trust the ability of attitude measures to predict choice outcomes.

If there is a change in the evaluation environment between the time of attitude formation and the time of subsequent evaluation, evidence suggests that specific performance information is more “diagnostic” than prior summary evaluations and, hence, will be used in favor of prior judgments. Consumers perceive prior judgments to be nondiagnostic if new brands, attributes, or usage situations are introduced into subsequent evaluation contexts (Biehal and Chakravarti, 1986; Lynch and Srull, 1982). Experiments designed to test Lynch and Feldman’s basic propositions have supported the framework (Lynch, Marmorstein, and Weigold, 1988). In one experiment, subjects were put in “mixed choice” tasks where they were forced to choose between a previously evaluated brand and a new brand. Subjects relied on attribute information, and not the prior judgment, to make the new evaluation if the

attribute information was accessible, ostensibly because the prior judgment had no diagnostic implications in the new evaluation setting.

Another reason choice and judgment processes are likely to differ is a decision involvement gap. One antecedent of decision-making involvement is the perceived risk associated with the purchase (Robertson, 1976). There is little risk associated with forming a “wrong” attitude when asked because there are no real consequences associated with the evaluation. In many product classes, however, there is considerable economic, social, and utilitarian risk associated to a “wrong” choice. This involvement gap between attitude and choice formation processes is likely to lead to evaluations based on different informational inputs and different decision rules. When this occurs, attitude-behavior consistency should be low. For this reason, survey measurement procedures that simulate the true “state of mind” (e.g., involvement) at the time of choice are more predictive of choice (Baker and Lutz, 2000).

Assuming equal levels of involvement at the time of attitude formation and choice and even identical evaluation processes, the correlation between brand attitude measures at time A and brand behavior at time B is still likely to be low unless involvement is high (Baker, 2001). Momentarily activated cues have a disproportionate influence over judgments made about an object or related behaviors performed shortly after their activation (Wyer and Srull, 1986; Kisieliuss and Sternthal, 1984). Environmental influences have a tremendous effect on salience. Cognitions that influence evaluation are cued to memory by contextual factors and only a small subset of the available information will be accessed at any one evaluation episode (Feldman and Lynch, 1988). Since accessibility is a function of the time since the most recent activation of that cognition (Wyer and Srull, 1986), attitudes measured at or near the time of advertising exposure are likely to be heavily biased by advertising content. Attitudes measured in another environment are likely to be driven by the most salient information in that environment.

Attitude-behavior consistency is likely to be particularly low when consumers engage in low-involvement decision-making behavior. In such a scenario, the latitude of acceptance

of alternative courses of action is likely to be high (Sherif, Sherif, and Nebergall, 1965) and evaluations are likely to be a function of highly salient contextual cues. Assuming that attitude measurement immediately follows exposure to advertising, the salient contextual cues are likely to be advertising effects. Assuming that choice takes place in a store, the salient contextual cues are likely to be packages and other point-of-purchase (POP) information for both the “target” brand and competing brands. When involvement is high, attitude-behavior consistency should be higher because evaluations are more dependent on deliberately accessed rather than cued information.

META-ANALYTIC EVIDENCE FOR ATTITUDE-BEHAVIOR CONSISTENCY

A series of meta-analyses have been conducted in recent years, which supports the theoretical arguments and empirical findings discussed above (Glasman and Albarracin, 2006; Kraus, 1995; Cooke and Sheeran, 2004). An examination of hundreds of studies indicates that attitudes correlate more strongly with behavior when they are (i) accessible and stable, (ii) frequently repeated, (iii) formed on the basis of direct experience with the attitude object, (iv) formed on the basis of one-sided rather than two-sided arguments, (v) formed in contexts informationally similar to the choice environment, and (vi) formed in environment characterized by high involvement. If one or more of these conditions do not exist, attitudes do not tend to reliably explain behavior. Certainly, the reliability of attitudes formed vicariously in contexts disparate informationally, motivationally, and in time from brand choice environment must be considered questionable in terms of their predictive validity.

SUMMARY

There are several barriers to using brand attitudes, advertising generated or otherwise, as reliable predictors of brand choice. First, brand attitudes may not be held toward brands in many product categories. Second, brand attitudes may be neither stable over time nor accessible at the time of brand choice. Third, a salient brand attitude must be perceived to be at least as relevant

as other salient information at the brand response occasion. Vicariously formed brand attitudes rarely possess such diagnosticity. Fourth, the attitude and brand choice process must be identical. Evidence suggests that this is not typically the case. Informational inputs and evaluation rules are likely to differ. Fifth, unless involvement is high at the time of attitude formation, the effects of varying environmental cues and time delays on information accessibility is likely to lead to different informational inputs to the brand attitude formation process and the choice process. The Feldman and Lynch (1988) framework reconciles much of the conflicting research on the role of prior judgments in a choice context. Its stated conditions for an effect of prior judgments on choice, accessibility, and diagnosticity, have stood the test of time.

In many respects, research on attitude-behavior consistency suggests that if brand choice is the ultimate focus of interest, then brand choice itself should be the dependent variable that is studied and tracked. If actual purchase behavior cannot be studied in a given situation and measures such as brand attitude or purchase intention must act as surrogates, then steps should be taken to match the research environment as closely as possible (i.e., information, motivation, competitive alternatives, reason for purchase, etc.) with the brand choice environment.

the role of creativity

George G. Panigyrakis and Prokopis K.
Theodoridis

INTRODUCTION

One of the most important components of an integrated marketing communications program (*see* INTEGRATED MARKETING COMMUNICATION) is the advertising message. As advertising is a form of communication, it involves a message that is communicated by the sender, usually the company, to the receiver, who is the consumer. The objective for the company is that consumers interpret the messages as the company intends. From everyday life, it is easy for everyone to realize there are various ways to convey an advertising message. However, it is the creative strategy that decides whether the advertising message is well presented and executed (Belch and Belch, 2009).

Good creative strategy and implementation both play an essential role in the success of a product or a service (*see* BRAND STRATEGY) and can diminish the progress of an already established brand. Conversely, an advertising campaign that is poorly implemented can result in the product being a failure. Creativity in advertising is one method applied by agencies to affect persuasion, and, eventually, behavior. Due to its purpose, advertising creativity is different from art creativity, because it must accomplish goals decided by other players. This is not generally an occurrence in the arts (Till and Baack, 2005).

Many ads have won awards for creativity but these ads failed to increase sales (*see* ADVERTISING EFFECTIVENESS), resulting in advertising and marketing people becoming critical. They argue that creative people in ad agencies are sometimes more interested in creating award-winning ads, than successful ads, which accomplish their clients' objectives. However, other advertising people believe awards are a good way to recognize creativity that often does result in effectiveness.

A successful creative idea is manifest. It is etched in the mind of the consumer and can have an enormous impact on sales. This is also consequential in the appointment or dismissal of

advertising agencies. Agencies that win creative awards secure more business and can therefore afford to retain better staff (West *et al.*, 2008).

Creativity is the foremost but least scientific aspect of advertising. It must possess impact, quality, style, and substance. Ideas must be original and moreover pertinent to the product and target consumer to facilitate beneficial solutions to marketing communications problems. "Creativity is the ability to produce work that is novel (i.e., original, unexpected)." Novelty is a required but inadequate prerequisite for creativity as it must also possess adaptability and appropriateness. (Sternberg and Lubart, 1996, p. 3). The combination of "novelty" and "appropriateness" or "usefulness" is generally accepted as taken. These notions are explored in the following sections.

CREATIVITY IN ADVERTISING

Creativity has been defined by every synonym of the word creativity, plus, value added, and acceptable. However, the most used descriptor of creativity in advertising appears to be *novelty* – a divergence from the norm – and a sense of uniqueness or originality. (Ang and Low, 2000). The foundation of creativity in advertising, similar to other disciplines, is knowledge. It has patterns, rules, conventions, language, and symbols. Creative ideas are novel. They are thoughts and/or images that are generally recognized but considered foreign to one another. Leo Burnett, when talking about creativity, supports this statement. When talking about creativity he did not use the term original. Instead, he referred to making meaningful associations between previously unrelated thoughts in ways that were relevant, believable, and in good taste (Burnett, 1968). Other researchers prefer the word original. (El-Murad and West, 2004). Original and novel appear to be analogous. However, the dissimilarity is of importance. Novelty is the quality of being different, new, or strange. Originality, conversely, is the state or quality of being newly created or formed, fresh. (Oxford Advanced Learner's Dictionary, 2009). Consequently, creativity in advertising, while appearing to be original, is in fact novel.

Although divergence is a central determinant of creativity, the ad must also be relevant. The

relevance component of creativity reflects the extent to which ad elements are meaningful, useful, or valuable to the consumer (Smith *et al.*, 2007).

While the consumer seeks relevance, practitioners, mostly regard creativity as business objective. Practitioners seem to be rather more in harmony with what their clients require and not necessarily with consumers. This may explain why creativity and its effect remain unpredictable. Consumers receive advertising messages according to their needs. Their opinion of creative can contrast from the presumption of creatives (West *et al.*, 2008). It is accepted that consumers and creatives disagree on creativity, but, there is insufficient evidence as to why. It has been attested that creative ads containing novelty, meaningfulness, and emotional content were perceived as more favorable, resulting in a more favorable view of the brand itself and increased purchase intent. It was also found that an ad considered to be creative is one that is unexpected, carries a pertinent message, and generates positive feelings (Ang and Low, 2000; Till and Baack, 2005).

“Creative” advertising and “effective” advertising are the concepts (*see* ADVERTISING EFFECTIVENESS) that most frequently appear in the literature (Ogilvy, 1985). However, even though creativity in advertising has been widely recognized as very important, the link between creativity and advertising effectiveness has not been extensively examined, leading to diverse opinions on the role and importance of creativity in advertising and marketing (Till and Baack, 2005).

In the business environment managers tend to value “effectiveness,” which is usually measured by changes in awareness levels, consumer attitudes, or in market sales, whereas creative people generally have a low regard for these types of measure. There are people who believe that advertising is creative only if it sells the product or services, and that the impact that advertising has on stimulating consumers’ purchase intention is more important than its novelty and originality. In contrast, others evaluate creativity in terms of innovative, inventive, and aesthetic values. They believe that creative ads can capture the consumers’ attention and influence decision making (Belch and Belch, 2009). Perspectives

on advertising creativity depend on one’s role, leading to many different views on how advertising creativity is perceived.

Even among trained advertising professionals, there is a lack of agreement, resulting in a struggle between those who create and those who manage. It has been also mentioned that even copywriters and art directors may have differing views. Part of the problem can be traced to what the various parties involved consider as priority. Clients are more concerned with strategic questions of appropriateness rather than issues of novelty. Product managers and account executives consider ads as promotional tools and evaluate them according to their impact on their clients’ objectives. Moreover, when referring to strategy and sales, appropriateness for them could also mean effectiveness, time, and money, as well as corporate values. Conversely, the art directors and copywriters consider ads as a medium to express and communicate their own points of view and their personal objectives (Hirschman, 1989).

Ultimately, it is the combination of these viewpoints that constitutes creativity in advertising and makes an ad effective and successful. Besides being original and interesting, an ad must make a good impression on consumers, trigger their attention and, influence their decision, as well as being original and interesting.

In the next section, a paradigm of creativity in advertising is presented through a systems approach incorporating all potential “actors” and influences on creativity.

A PARADIGM OF CREATIVITY IN ADVERTISING

The creative process is not just one person with “the idea.” There are several other inter-relational sectors and players to consider. They can be placed into four categories: The field, the domain, the creators and the external environment (Csikszentmihalyi, 1999), all parts of which have an influence on the whole.

The field workers: the account handler, research department, accounts services, accounts planning, creative director and clients brand managers, category managers, marketing directors, and a chief executive officer, and

included occasionally are the audience – the customers.

The domain: the product, competitors, marketing communication.

The creators: the writers, the arts department, and the creative director.

The external environment: photographers, film directors, costume designers, and all other relevant media people.

It all begins with an “advertising brief,” given to the agency’s account handler by the client. This brief consists of a few standard parameters including the general message the client wishes to communicate, details of the product/service, and selling points. The client will also suggest which medium is to be used, that is, TV, press, radio, or direct marketing, and inform the agency of the maximum budget. The client’s main contact in the agency is the “account handler,” whose job it is to turn an ad brief into a creative brief. This is done by using the services of all departments in the “field,” especially research, who examine the “domain.”

To facilitate the creative process, many agencies now use account planning. Planners work with the client as well as agency personnel, to discuss how information they have gathered can be used in the development of the creative strategy.

The account handler then presents the final brief to the creatives. His brief contains information on the target market, the message, and the media requested by the client.

The creatives then work on proposals. A creative team consists of an art director and a copywriter; a mixture of pictures and words.

Now the proposed ad has to be priced. This is where production, also known as *traffic*, enters. It is their job to take into consideration the countless factors and elements that go into physically producing the ad. They deal with all players including the “external environment.”

The creative director is not only responsible for the quality of the final creative work but also has the task of creating harmony amongst all the players. This can be a very difficult task as tempers can rise (for example, a creatives idea is blocked by accounts) or the client, through the account handler, insists on a location or actor not

included in the budget. They are often praised highly when their team’s efforts win awards, but conversely, the creative director shoulders the negativity when a project goes wrong or response falls short of expectations.

CREATIVE STRATEGY – APPROACHES AND APPEALS

Planning creative strategy is a great challenge. For those who work on producing the ads, it is very difficult to create an ad that is unique, innovative and at the same time effectively communicates the advertising message. Ads must be novel, unusual, meaningful, and relevant to the consumers’ interests and needs. It is often difficult for the creative team to accomplish such a challenge and create an effective and successful advertisement. Advertisement, as every marketing situation, is different and each campaign requires a different creative approach. Every client has his/her own specific goals and objectives that need to be achieved. Many creatives believe that clients must take some risks, if they want to create an ad that will break through the clutter and grab consumers’ attention, but not all companies or agencies have the same opinion. Many managers argue that being risky is not always effective.

In the context of winning creative ideas, risk-taking perspectives may limit the number of creative ideas produced and offered. An agency working for a client who is antirisk will need to limit creator imagination. Simultaneously, an agency that is antirisk will behave in the same manner. Therefore, risk is necessary to develop original creativity (Belch and Belch, 2009).

The literature supports the fact that the client will have the most influence on the advertising agency’s risk taking. It is often the case that for smaller clients, advertising agencies are likely to propose greater risk taking. This implies that given the consequence of potential failure, agencies are likely to attempt to protect themselves from negative impact (El-murad and West, 2003).

The popular belief is that creativity in advertising is best considered as a process. An organized approach to problem solving to develop a creative advertisement is a safe way for success. James Webb Young (2003), developed one of the

4 the role of creativity

most popular approaches of the creative process, containing five steps:

Immersion: gathering information through background research.

Digestion: thinking about the information and working on them.

Incubation: putting the problems into perspective.

Illumination: coming up with a great idea.

Reality or verification: refining the big idea.

There is however, a six step plan derived from the previous approach. These steps are used by the majority of advertising agencies presently and are: Discovering, Strategizing, Creating, Evaluating, implementing and finally Measuring.

These six steps plus the full creative jargon are now presented.

Discovering. This involves the preparation and collection of useful background information and is the initial step in the creative process. It is very important to not only understand and identify the nature of the company and the product but also, those of competitors. Actual customers, target markets, economic environment, social trends, and new developments in the field must be taken into consideration. This research is indispensable for complete comprehension. Agencies must possess savoir-faire to synthesize the information they gather in order to develop an advertisement. To facilitate the process, many agencies now use account planning which is a process focused on clients wants and needs. One must first know the product in order to create an effective advertisement. Quantitative and qualitative research facilitates this procedure (focus groups, ethnographic research) facilitates this procedure enormously (Belch and Belch, 2009).

Strategizing. This is the analysis of all the discovery facts to find interesting relationships that lead to the exploration of creative procedures. The decision is then made to either focus on a single strategy or an interteam task where ideas are considered. The task is then passed on to the creative department.

Creating. Selecting the campaign, organizing a work plan, and finding the big idea of the

campaign are taken into consideration at this stage. For an ad to be successful, it must contain a unique idea that captures the consumers' attention. The ad also has to appeal to create a positive reaction toward the product. Furthermore, a creative ad has to ensure that the product or service is differentiated from competitors' offers.

It is quite difficult to put all these together in order to create a successful ad, but there are some approaches that can assist the creative teams in developing an effective advertisement. These include *using a unique selling proposition (USP), creating a brand image, finding the inherent drama, and create positioning.*

As Rosser Reeves (1961) stated, a USP has three major characteristics. First, each advertisement must make a proposition to the consumer, not just promoting selling. Second, this proposition must be original and attractive for the consumer, and third, it must be strong enough to motivate new customers toward the brand.

Creating a brand image is also very important in creative strategy. The image and the personality of the brand should be strong, easy to memorize, and have an appeal to the potential users. It must also differentiates the product from similar ones.

Another approach is *finding the inherent drama*, or the special characteristics and benefits of the product or service that make the consumers want to purchase it.

Finally, *positioning* holds a great role on determining the major selling idea, because it establishes the product in a specific place in the consumers mind.

Different advertising appeals are used to intrigue consumers' attention, attract their interests, and influence their feelings toward the product. They motivate the consumers to have a positive reaction. There are several categories/approaches of advertising appeals.

Informational/rational appeals focus on the logical view of the consumers. Their intention is to promote the benefits of the product or service that satisfy consumers' realistic needs. They emphasize on the practical effects of the product, such as quality and/or, efficiency that are important to consumers and increase their purchase intentions.

Emotional appeals focus on exciting customers' feelings. They are designed to influence consumers on an emotional level and affect their

social and psychological needs. Many consumers are thought to follow their feelings to make a decision and pay less attention to the rational benefits that a product or a service offers.

There is also a combination of *rational and emotional appeals* that are used to appeal to consumers that make their decisions based on both emotional and practical motives, to purchase a product.

There are also additional types of appeals that differ from rational and emotional appeals, and can be classified as *reminder advertising* and *teaser advertising*. Reminder advertising focuses on building brand awareness and teaser advertising focuses on building curiosity and excitement about a product or a brand.

Advertising execution relates to the way advertising appeal is used to communicate the advertising message and how it is presented. An advertising message can be executed in various ways (Belch and Belch, 2009):

Animation: a recent and also popular approach, usually for commercials targeting children (creative, entertaining ads).

Combinations: combinations of two or more execution techniques.

Comparison: a direct way of communicating a brand's particular advantage over its competitors.

Demonstration: illustrating the key advantages of the product/service by showing it in actual use.

Dramatization: focusing on telling a story with the product or service as the star.

Humor: a type of appeal but also a way to express/present other appeals.

Imagery: the ad consists primarily of visual elements such as pictures and illustrations an symbols rather than information.

Personality symbol: developing a central character or personality symbol that can deliver the advertising message and with which the product or service can be identified.

Scientific/technical evidence: cite technical information, such as the results of scientific studies to support the advertising claims.

Slice of life: on the basis of a problem/solution approach, portraying a problem that consu-

mers might face in their daily lives, with the ad showing how the product can resolve it.

Straight sell or factual message: a straightforward presentation of information concerning the product or service.

Testimonial: using a person to praise the product on the bases of his/her personal experience with it.

Priken (2004) provides more ideas in ad execution.

Execution styles – the kickstart catalogue.

Absurd, surreal, bizarre: associating the brand with absurd or bizarre ideas, representing the benefit of the brand with a surreal or fantastic situation.

Alternative media: using an outdoor site or installment, trying to find unconventional ad formats, using familiar places or objects in a provocative way.

Alternative uses: finding new use of the brand into a context or environment, and revealing a new perspective.

Break out of frame: using the advertising medium or its context or an altering version of it into the advertising.

Change of perspective: showing objects or situations from unusual viewpoints that is, extreme close-up or distance, or take on other identities.

Change the product: the way of presenting the product differently to the audience changing its shape, use, location, packaging, whatever can be changed.

Come and play: involving the audience in a game.

Comparative juxtaposition: or “before and after” – making the benefit of the brand obvious by a comparison.

Double meanings: visual (optical illusions) or verbal (word play or suggestion), involving double meanings.

Exaggeration: description of features of the brand, problem situations, or solutions that can catch audience attention and emphasize the benefits.

Metaphor and analogy: comparing the benefit of the brand with something similar.

Mixing and matching: combination of two concepts or objects to produce something new.

Omission and suggestion: missing or incomplete information, replacing with something that emphasizes its USP.

Paradoxes: a contradictory statement emphasizing the benefit of the brand.

Play with words: using typography of the words, symbols, or logos to represent the benefit or the USP of the brand.

Playing with the time: making the effects of time visible, put the brand in the spectrum of time either in the past, present, or future.

Provocation and shock tactics: challenging, inciting, and stimulating the audience.

Reframing: providing a key to creative thinking.

Repetition and accumulation: disrupting a regularly repeated pattern.

Spoofs and parodies: changing a well-known brand, cartoon, slogan, book hero, and so on, in order to conflict with original function and character, providing a new meaning.

Symbols and signs: using symbols, signs or combination of them to present brand benefit.

Take it literally: translate the words or phrases into a picture.

Telling stories: everyday stories around the brand following a dramatic style, such as adventure, love story, drama, documentary, news, or thriller.

Turn it right around: doing the opposite of what one would expect, using features of the brand, benefits, packaging in an opposite way.

Without words: telling stories in an effective way without using words, depicting USP without words or in a silent way, portraying the brand benefit in one picture (Priken, 2004).

Once the creative process is terminated the proposed campaign then passes to the evaluation stage.

Evaluating. Further research and testing methods to select the final campaign are then implemented. It is usually the client who

is responsible for the final decision as to effectiveness.

Implementing. The plan is then executed.

Measuring. Results are measured and evaluated. Adjustments if required are implemented.

The role of creativity is clear as it has to result in an improvement in achieving organizational and more specifically marketing objectives. Effective advertising must contain a unique idea that captures consumers' attention, attracts their interest, and stimulates them to have a positive reaction toward the product. At the end of the day, creative advertising should facilitate the product or service to be discerned from any other creation including those of competitors.

IMMINENT INFLUENCING TRENDS

Presently there appears to be a dilemma on the future of the actual creative processes and the advertising agency in general.

To analyze future trends, brand managers/ambassadors of global products were contacted. Surprisingly, the results appeared obvious as all managers/directors responded likewise. Permission was granted to cite one of the global distribution companies; Pernod Ricard, who deal in alcoholic beverages. Their Jameson Irish Whisky Ambassador, Graham Wood, said the following:

The key role at the moment is the Media Shop because it is far too expensive to run an in-house creativity department. We are aware that there will be a big internet explosion. However, presently solid data/research is lacking.

The internet is most definitely the future. Presently we are seeing unpredicted phenomena. Sites such as *Facebook*, *YouTube*, *MySpace* and *Twitter* are rapidly increasing their membership. All these sites support the political, commercial, sportive, humanitarian, and personal messages.

Facebook will most probably emerge as the site for all age groups, nationalities, and genres (see SOCIAL INFLUENCE). The use of Facebook for sending political messages debuted with President Barack Obama. On his official page created prior election he had seven million 'friends' globally in less than a week. This is not including the 500 plus unofficial pages with over 30 million friends/fans. Future policies are

forwarded and all “friends” may comment, send ideas, and or question the policy. Commercial brands are slowly appearing officially and unofficially obtaining several thousand friends/fans in less than a day. Where sport is concerned the major European football clubs are presented again officially and unofficially. Humanitarian groups, for example; “Feed a child with just a click” has nearly five million members.

YouTube is a video site and previously catered to a younger audience. Since the debut of the share option, with a mere click members may send videos to their Facebook or MySpace pages and to email accounts. This has created a surge of new, all age members. The impact is enormous. Susan Boyle, a Britain’s Got Talent contestant, did not win the competition but still became an overnight global star due to the site. Ten million people globally saw her video in a weekend. The Obama music video ‘Yes We Can’ had over 19 million hits in the same period. Advertisements and their spoofs are well positioned especially if they are humorous.

MySpace members use their pages for storing photos, videos and playlists. This site is used mainly by a younger audience promoting their personal music and videos. It also permits “friends”. Taken at random and contacted an unknown “Mr. Dialysis” a hip hop rapper has for example over 15,000 fans who left over 10,000 comments on his page. The site also features a contact icon which has permitted promoters to contact with gig offers. Mr. Dialysis states “My Space permitted me to get my music and lyrics out there”.

Twitter, is the text “what am I doing right now” site and has a large following. However its appeal is diminishing amongst the older audience because of the “stalking” perception. The British Government found the site interesting and posted a generously paid job offer for a general public termed “twittercrat”.

For marketers there will be the problem of keeping their page unique by somehow blocking the myriad of unofficial pages, or allowing these pages to propagate the message further. The danger lies in the unofficial who distorts the message or the embarrassment of a spoof that betters or negates the original.

Finally, it is evident that academic research is desperately needed, based not only on Internet

possibilities, but which sites, what form of media, and how to “control” the message. Also an empiric study is also needed on Media Placement Specialists, an expanding business open to all due to increased Internet usage.

marketing functions on the Internet

Larry Chiagouris and Alexis Verniere

The commercialization of the Internet, which began in earnest in the mid-1990s, has generated substantial opportunity. Prior to 1996, however, there was no significant body of research that could be relied upon for direction on how to take advantage of the promise of the Internet. One of the most extensive research reviews found that through 2003, there still remained much to be learned and shared about how to best conduct business on the Internet (Cho and Khang, 2006).

Much has changed since 1996. Marketing functions that are conducted in the traditional brick-and-mortar world also can be found operating within the Internet. Managers have now translated marketing functions to work in an on-line environment, including functions such as market research, product development, branding, communications, pricing, and retailing. They have done so while having to develop realistic business models and addressing consumer privacy issues. The following examines each of these areas.

MARKET RESEARCH

It has been estimated that the majority of quantitative data collected in the United States is now collected on-line. Qualitative research is also growing by connecting people with a moderator on-line in order to explore marketing and product-related issues.

The documentation of using the Internet to conduct market research can be traced to the very early period of the commercialization of the Internet (see Berry *et al.*, 1994). Internet market research has had a tremendous impact on how marketing decisions are made. Market research on-line can be conducted with greater speed, lower costs, and improved accuracy as compared to off-line methods (Lockett and Blackman, 2004). Internet market research allows consumers to examine products, concepts, and test advertising from the comfort of their own home and provide their reactions as to what they like and dislike about products and tactics. Importantly, because of the declining rates of

cooperation in off-line research, on-line research is becoming the most common form of market research.

Key to the growth of the use of market research over the Internet have been research studies that were launched to compare the results of on-line research methods with the more established off-line methods. While there can be some important differences, credible research has found that the results produced via the web are comparable to what would be expected in using more traditional off-line methods (Kaplowitz, Hadlock, and Levine, 2005).

One way that on-line research is being used is through feedback obtained via on-line communities. These communities are being formed through social networking sites such as MySpace and Facebook. Research with on-line communities allows companies to become better acquainted with customers and identify and leverage new trends in a timelier fashion (Casteleyn, Mottart and Rutten, 2009).

Similar to other research methods, market research conducted over the Internet has several issues and challenges. The issues and challenges include too much data to decipher, low response rates, and the delay in implementing new methods of market research.

A growing body of research and literature has emerged as to what to do and what to avoid in order for on-line research to be conducted effectively. High on the list of suggestions is the need to keep the survey short, and assure that it has been properly pretested and conducted among a representative sample of the external audience that it is intended to represent.

PRODUCT DEVELOPMENT

The Internet has greatly enhanced the participation by consumers in the product development process. Through user-friendly development tools and the expansion of broadband service, customer participation in product development has changed the process of product innovation.

The benefits to marketers include lower product development costs, faster development times, and increased customer relevancy of new products. There is also some evidence that the Internet increases demand for products early in the product launch phase (Prince and

2 marketing functions on the Internet

Simon, 2009). This is due to consumers having improved access to information in addition to the convenience of on-line shopping.

There are many examples of this form of product innovation. Companies have been able to develop and distribute software-based design tools or “tool kits” that allow lead users to work with the companies to make new products or refine existing products and services. For example, more than 80% of computer game companies have on-line user communities that are used to develop new product opportunities (Jeppesen and Molin, 2003).

An extension of the Internet in the product development process is the concept of virtual reality. Here, consumers are able to project themselves into three-dimensional spaces. They can interact with products (through an avatar that represents their persona) under the supervision of the product development team.

This use of virtual reality is becoming recognized as holding great potential to impact product development programs in the future (see Ottosson and Holmdahl, 2007; Mackenzie, Buckby, and Irvine, 2009). Some companies, however, are concerned that they may lose control of the product development process to their user base. Therefore, these companies are seeking to reign in user-driven development efforts over the Internet (see Braun and Herstatt, 2008).

BRANDING

One of the first articles to address branding on the Internet (see Chiagouris and Wansley, 2000) addressed the challenge of how a brand can transition prospects to customers and build relationships. The Internet has major advantages over mass media. Mass media cannot communicate with individual prospects in a customized way based on the different stages of the relationship-building process.

Rather than simply interrupting a television show with a commercial message or barging into their lives with unannounced phone calls or letters, innovative marketers first try to get individuals to voluntarily enroll in the relationship-building process. A volunteer's experience will almost always be more likely to result in the embrace of a brand than any forced

viewing experience. Interactive technology enables marketers to inexpensively attract consumers into one-to-one relationships fueled by two-way “conversations” played out via mouse clicks on a computer.

There are many design elements that can accomplish the objectives of moving a prospect along the brand relationship-building continuum. These techniques range from brief registration forms that begin the relationship-building process to games that intrigue the user on a category-relevant subject. There are also programs designed to identify if the user has visited the site before and greets/treats the user in a manner that reflects this knowledge.

Amazon.com provides an excellent example of how to build a relationship on the Internet. Once a customer buys a book from it, Amazon.com begins collecting information and making educated guesses about what might appeal to this person. Then it makes book selections and gently guides the individual toward other choices. It does so by creating communities of special interest groups (e.g., art, cooking, or sports) and offering appropriate links throughout the site. Today when a customer logs on to their website, Amazon.com provides a message of “personal recommendations” which is based on selection criteria.

Traditional marketers like Procter & Gamble (P&G) have also engaged in Internet branding. P&G also demonstrated creativity in their Internet branding campaigns. One of their most successful interactive campaigns was the Scope e-mail kiss. The campaign generated an average click-through rate of 20%, with an even higher conversion rate of pass-along e-mails.

While Internet branding shares much with traditional branding methods, there are some important distinguishing characteristics. Internet branding consists of fluid strategies regarding new products and campaigns rather than finite starting and ending points. Internet branding does not have the tangible collateral that off-line branding requires. Importantly, Internet branding addresses the individual interests of the customer rather than treating all customers alike.

Although the theoretical foundation of branding on the Internet is still in an emerging stage, scholars have identified key issues and

suggestions for effective branding. For example, providing the appropriate cues and symbols for a brand on-line can contribute to a more effective brand presence. In particular, building brand alliances with respected and established brands can contribute to a more effective brand presence (Delgado-Ballester and Hernandez-Espallardo, 2008). This is particularly the case if the brand alliance is promoted on a brand website.

In a similar fashion, use of trustmarks, such as BBBOnline or TRUSTe can be a more effective tool in boosting brand imagery than ratings from magazine articles or paid advertising support. These third-party graphic images placed on a website can decrease the anxiety that shoppers have about purchasing something on-line. These marks add to the quality of the brand imagery of an on-line brand.

The measurement of on-line brand equity is also becoming increasingly important. Scholars have found that there are a number of tactics that will enhance on-line brand equity. These tactics range from the creation of on-line newsletters and magazines (Müller *et al.*, 2008) through to on-line programs that telegraph personalization (DaSilva and Faridah, 2008).

MARKETING COMMUNICATIONS

The Internet, as an advertising class, provides some of the most varied forms of marketing communications. The type and nature of forms of marketing communications is highly varied and constantly evolving. According to a 2009 report from investment bank Morgan Stanley, marketers now consider this form of communications more effective than television or newspaper advertising. Internet advertising is expected to receive 15% of all global advertising spending in 2010 (Group, 2009).

Early in its development, the absence of standardized creative units presented many challenges to the marketing and advertising industry. As a result, the Interactive Advertising Bureau (then called the *Internet Advertising Bureau*) worked with on-line publishers, advertisers, agencies, and media companies to create a set of voluntary guidelines. These voluntary guidelines are now in use in creating, planning, buying, and selling of interactive marketing and advertising.

The standards address a wide variety of advertising formats, including rectangles, pop-ups, banners, buttons, and skyscrapers. The standards specify the sizes in terms of pixels as well as file weight and maximum time for the loading of rich media (ads that use advanced technology such as streaming video or programs that interact with the user).

Marketers seeking to place ads on the Internet can do so through a variety of ways. The most popular ways are to work with an ad network or directly with an on-line publisher. Recent research indicates that if carefully chosen, working with an on-line publisher directly is likely to lead to better results. On-line publishers are a critical component of marketing-related considerations and marketers often partner with on-line publishers to achieve their objectives.

The principal functions of an on-line publisher that operates a website on the Internet consists of creating content, producing it in a manner that it can be uploaded to its website for viewing by the people who visit its website, and then generating traffic in the form of visitors to its website. Advertising revenue is the most common form of revenue for on-line publishers. Advertising revenue is generated when people who visit the site are exposed to the ads on the site from advertisers. Usually, the advertisers will compensate the operator of a website that displays their ads based on the number of people who have been exposed to the advertisers' ads.

The conditions under which banner advertising has been found to be effective vary. For example, brand recall is higher for a banner ad when the ad is relevant to the content found on the website in which it appears (Yaveroglu and Donthu, 2008). The Internet is evolving into a mature medium, however, and it has exhibited an effect referred to as *banner blindness* (Cho and Khang, 2004). This effect is a condition in which consumers ignore banner ads found on website. As a result of some erosion in the effectiveness of banner ads, marketers are increasingly using search engine marketing (discussed below) and e-mail marketing in their marketing communications plans.

In terms of e-mail marketing, 50% of consumers indicate that they are more likely to purchase products from companies that send them e-mail (Epsilon Branding Survey, 2009).

4 marketing functions on the Internet

Two-thirds of consumers have indicated that they have purchased something because of a message that they have received within an e-mail (ExactTarget, 2008). E-mail marketing is now more than a \$1 billion industry. As such, a substantial amount of attention is being given to e-mail marketing programs by marketers. Effective e-mails often contain information of interest to consumers, sometimes coming in the form of a newsletter. The most effective forms of e-mail marketing are the ones that utilize an opt-in process to build the e-mail list.

Single opt-in occurs when a consumer clicks on a link or a button and indicates a willingness to receive an e-mail from a particular company. Double opt-in is considered to be even more effective. This occurs after a consumer clicks on a link or button. That process is, in turn, followed by the consumer receiving an e-mail in which they then have to click on a link within the e-mail to increase the certainty that the consumer wishes to receive e-mails from a particular company. All must abide by spam regulations, which require the need to allow consumers to unsubscribe to an e-mail solicitor.

Advertising on the Internet has evolved to take on many new forms and on devices other than computers. In terms of content, social networks, blogs, and other techniques that leverage user-generated content are becoming more popular. There are some lingering questions, however, concerning whether these newer forms of content will have sustainability. Revenue for MySpace declined 16% in the first quarter of 2009. Bloggers who are at times considered a part of the journalism sector have come under closer scrutiny for bending principles of traditionally accepted journalistic ethics.

In terms of devices, the mobile phone has captured the attention of marketers. Influential articles that address mobile phones as a marketing tool began to emerge in 2005 (see Sultan and Rohm, 2005). This form of advertising is now adapting Bluetooth technology to provide sponsored alerts to prospective customers.

Mobile phones are also supporting short message service (SMS) capabilities that facilitate advertiser messages. Sponsored entertainment over smart phones with large screens can be

expected to become a popular application in the future. The key challenge for some advertisers, however, is to create websites that employ the wireless application protocol (WAP) so that the appearance of the website on the mobile phone is easy to comprehend and the features easily used. The industry will also need to be sensitive to some consumers finding advertiser-supported messages intrusive on their cell phones.

Additional challenges are expected to confront advertisers in the future. One challenge is that consumers using the Internet may not always be attentive to it. Nielsen reports that more than half of all consumers are doing something else when on the Internet. An environment in which consumers are multitasking when interacting with the Internet is currently a major challenge to advertisers in seeking to get the most return for their investments in the Internet.

PRICING

The Internet has made it increasingly easier for consumers to know at both wholesale and retail levels the prices that are being paid for goods and services. While all traditional brick-and-mortar pricing strategies apply to the Internet, there are some approaches to pricing that are either specific to or greatly enhanced in an Internet business.

Dynamic pricing is a term for a pricing strategy in which the seller changes prices either over time or across products or segments of consumers (see Kannan and Kopalle, 2001; Jallat and Ancarani, 2008; Kumar and Sethi, 2009). The Internet has made it easier for both parties to a transaction to adjust willingness to pay (buyer) and to adjust the price of the product or service (seller).

Dynamic pricing can take a variety of forms with two of the most popular being the updating of prices by the seller (e.g., airlines) or the arrangement of an auction in which potential buyers bid against each other to acquire a product within a specific time frame. With regard to auctions, the supplier can usually expect to pay a commission to the entity arranging for the auction and that commission is usually factored into its cost structure and ultimate price point.

In terms of auction-site pricing, there is research that suggests that consumers in certain parts of the country are more willing to pay

higher prices than those in other parts of the country (Bland, Black, and Lawrimore, 2007). In the same research, there is an indication that women might be willing to pay more than men for a product in an auction environment. Willingness to pay may also decline when similar items priced at different levels are listed in an auction environment or when the prospective bidder has an extensive bidding history.

Variable pricing is yet another form of pricing made possible by the Internet. In this case, the consumer may not be willing to pay a listed price. Here, the price can be lowered if the consumer is willing to accept certain limitations. In a popular example at Priceline.com, the consumer may have to travel on a flight or at a time of day determined by the supplier. In another example, progressive insurance, the consumer names his or her price and some key attributes but then accepts the remaining terms and conditions of the insurance policy.

Another pricing strategy is the cost-of-acquisition pricing strategy. It is based on a determination of the cost to acquire a visitor to a website and then the probability that the visitor will purchase something. On the basis of this cost, which is based primarily on the cost to drive traffic to a website, the business applies its margin in order to reach profit objectives.

Digital products and services often have low or zero marginal costs. For these, a value-added pricing strategy will often be used. The price is not driven by costs but by how much value the seller believes that the buyer will receive. This "value" is often determined through the use of marketing research studies.

ON-LINE RETAILING AND CUSTOMER SERVICE

According to the US Census Bureau, e-commerce sales in the United States was more than \$125 billion in 2009. Analysts at Goldman Sachs expect more than 15% growth in e-commerce sales in 2010. The majority of consumers have now become on-line buyers. Internet retailing has become mainstream.

The growth in on-line sales is particularly robust, given that the shopping cart abandonment rate was 48% in 2005 (eMarketer, 2006) and some estimates put the rate of abandoning

an on-line shopping cart as high as 75%. The reasons that consumers provide for not completing an on-line transaction are quite varied and on-line retailers are continuing to work toward overcoming prospect concerns. The opportunities and concerns incorporate the design of online stores, changing attitudes and behavior and providing strong customer service and relationship-building programs online.

In terms of on-line store design, there are a wide variety of considerations related to retail store design in the brick-and-mortar sector that have on-line equivalents. Similar to the off-line environment, the on-line retail environment must have an atmosphere that can make a difference to prospective shoppers (Eroglu, Machleit, and Davis, 2003). The on-line retailer can adjust, manage, and manipulate a variety of cues that contribute to the shopping experience. Many visual and auditory stimuli can be addressed to enhance the on-line shopping experience.

The consumer's attitude toward a website is important in his or her intention to purchase from it or come back to it. Factors affecting attitude toward a retail website include ease of use, product information, entertainment, trust, and currency—having everything on it up to date (Elliott and Speck, 2005). Importantly, not all Internet visitors react the same way to a website. For example, in the Elliot and Speck study, low-involvement shoppers who rated a website entertaining were also likely to rate it favorably. High-involvement shoppers were more interested in how current a website was, and rated it favorably if everything was up to date.

Attitude toward a website also differs depending on the shopper's level of experience. Inexperienced shoppers are likely to favorably rate websites that they perceived as easy to use. Conversely, product information on a website appeared to sway experienced shoppers more. They favorably rated websites that fit their information needs.

Creating trust is an important consideration in on-line retailing. If a consumer does not trust the offerings on a website, then he or she will not purchase anything from it. Dimensions of website design that contribute to consumers' perceptions of trust include visual website design, content design, and social-cue design (Wang and Emurian, 2005). The last item

6 marketing functions on the Internet

encompasses all of the potential for consumer interaction with a website, as well as the use of multimedia.

Consumers with different levels of experience can be expected to react to on-line retailing offers in a way that mirrors their on-line shopping skills. Experienced Internet shoppers rely more on the efficiency of the shopping experience, 24-h availability and the desire to avoid waiting lines/queues (Karayanni, 2003). In another work, it was found that more experienced shoppers found merchandizing tactics more impactful at building on-line trust, while inexperienced shoppers rely more on fulfillment, promotion, and website design (Jin, Park, and Kim, 2008).

An important component of any on-line selling environment is the customer service that is provided for visitors. In a recent survey by Harris Interactive and Tealeaf Technology, it has been reported that 57% of on-line shoppers would be less likely to buy from a brand off-line if they experienced problems on-line (McEleny, 2008). In effect, providing effective on-line customer service not only impacts Internet sales but it also has the potential to influence off-line transactions.

Underscoring the linkage between on-line and off-line businesses, it was also reported that 89% of consumers believe that on-line customer service should be the same level or better than shopping in a store. Importantly, 49% of consumers who experience problems with on-line transactions indicate that they would abandon or switch the transaction to another site – up from 37% in a similar survey conducted in 2007.

One emerging field to address customer service issues and concerns is electronic commerce customer relationship management programs. These programs are emerging as an important part of managing customer service programs over the Internet (Ratnasingam, 2008). The programs incorporate the use of applications to manage customers and customer interactions on the web.

Properly used, customer relationship management programs allow a company to reduce the costs of communicating with customers, improve customer interaction with the firm, and lead

to service improvements. Marketers are recognizing its importance and are investing in related software. For example, estimates provided by the Gartner Group indicate that spending on on-line community social networking technologies software neared \$400 million in 2008.

Discontent with service recovery by customers has been observed to be increasing (Holloway and Beatty, 2003). Responding to service problems in an on-line environment, however, has been found to be uneven across companies. There apparently are differences between how large companies and small companies address on-line complaints. Larger companies appear to provide more channels for their customers to register complaints compared to smaller companies (Neale, Murphy, and Scharl, 2006).

Recognizing that there are differences between on-line and off-line environments, measures of service quality are beginning to emerge that have been developed specifically for the on-line environment. These scales incorporate the dimensions of efficiency, fulfillment, system availability, privacy, responsiveness, compensation, and contact (see Parasuraman, Zeithaml, and Malhotra, 2004). One scale under development is the “eTail” quality or “eTailQ” (Wolfenbarger and Gilly, 2003). Website design, fulfillment/reliability, privacy/security, and customer service have been identified as predictive of eTailQ.

INTERNET PRIVACY

On-line businesses often utilize extensive data-gathering methods in order to target the right customers. These methods include data mining and conducting surveys. These methods also include a technique referred to as *behavioral targeting*. Behavioral targeting uses information collected during the browsing session by a visitor to a web page. This is accomplished by a website page placing a cookie (small file) on the hard drive of a consumer's computer. This cookie is the basis for sending information back to the company or companies involved in tracking consumer behavior.

Companies can use information generated through behavioral targeting to identify what pages are visited by consumers. Marketers expect

that this will aid them in delivering their on-line advertisements to the users who are most likely to be interested in the advertisements. Behavioral targeting is often used in conjunction with other forms of targeting to include information based on factors like past purchases, geography, and demographics. The assumption is that targeted ads will generate higher levels of purchase interest in consumers.

Personalization can be a very effective method to market to specific customers. Even though the results from personalization can be beneficial, the act of personalizing marketing efforts over the Internet may be seen as intrusive or an invasion of privacy. Over the last decade, privacy concerns of on-line users have been on the rise (Yang and Wang, 2009).

Behavioral targeting, in particular, is viewed by some consumers and consumer groups as an invasion of privacy. As a result of consumer push back, Internet privacy laws that restrict the use of behavioral targeting may be enacted in the future. Lawmakers have not reached a consensus as to what are the key threats related to Internet privacy. There is also a question as to how far to extend legislation and specifically, whether or not to limit legislation exclusively to e-commerce.

Privacy concerns are not equally shared by consumers. For example, gender can be a moderator variable in terms of the level of consumer privacy concerns. Recent research found that girls tend to exhibit greater privacy concerns than boys (Seounmi and Hall, 2008). In addition, girls and boys differ with regard to how much and what kind of information they share in the process of registering with a website.

BUSINESS MODELS AND TRAFFIC GENERATION

Websites designed for selling products and services or informing and entertaining have the ultimate objective of providing a return on investment. Many early Internet businesses did not have business models that produced profit. As such, discussions concerning business models in connection with the Internet have been extensive. While there are many variations and combinations of business models, a few have

emerged to become more recognized as effective ways to conduct business on the Internet.

One form of revenue generation is a business model based on e-commerce. In this form of revenue generation, an Internet organization sells products or services and takes some portion of the sale price as revenue. This model often requires substantial negotiation concerning prices paid and commissions earned.

Another form of revenue generation is based on what is called a *subscription business model*. Using this form of business model, an Internet organization charges visitors a subscription fee in order to access information or services provided by it. Well-established newspapers in particular, have been seeking to transition to this form of revenue generation. Financial services organizations that provide stock-picking tips also are seeking to adopt this business model.

Pay per click is another form of revenue generation in which search engines play an important role. Internet organizations receive revenue from advertisers or the agents of advertisers (search engines). In return, the Internet organizations allow advertisers' ads to be placed on their respective websites so that visitors to their websites will be exposed to the advertisers' ads.

Pay per click creates revenue if a visitor clicks on an ad that he or she is exposed to when visiting a website. The operator of the website receives a fee for each visitor who clicks on the advertiser's ad. Text ads on search engines are often the form of advertising used and "clicked on". Google, Yahoo!, and other search engines often use this form of advertising revenue generation. Operators of websites also allow Google to place ads on their respective sites. If a visitor clicks on these ads, Google receives a fee from the advertisers of the sponsored ads. Google then pays each of its participating sites a portion of that fee for allowing the placement of Google provided ads on their sites.

Pay per click is often used to generate traffic to a website. Fee for traffic is the money that one business on the Internet pays another business (or person) on the Internet in return for the second business sending people to visit the website of the first business. The reason why the first business described above is willing to pay a fee for this traffic is that it expects to generate more business directly related to the

number of people who visit its website. It is important to note that the amount of the fee is directly related to the amount of the traffic. In other words, fee for traffic is customarily priced in such a way that the total fee charged is based on the total number of visitors and amount of traffic sent by one entity to another entity.

Businesses often will place links on their sites to other sites. They do so in anticipation that people who visit their sites will click on the links and then be taken to a different site. If that happens, the second site pays the first site a fee for the traffic. The name often given to this relationship between the two sites is an *affiliation* and it is often formalized in what is called an *affiliation agreement*.

In considering tools to generate traffic generation, pay per click is quite popular and is an important part of the area of practice referred to as *search engine marketing*. Another complementary tool is search engine optimization. This takes the form of an operator of a website modifying the words and images that appear on its site so that search engines will increase the likelihood that the website will be listed in its results that appear to a user who searches for something on the search engine. These results appear in the section of results that are not sponsored or the section sometimes referred to as *organic results*. The challenge here for the website operator is to constantly manage and modify its search engine optimization efforts in order to remain popular with search engines.

comparative advertising

Larry Chiagouris

Pepsi versus Coke, Mac versus PC's, Dunkin' Donuts versus Starbucks, or Avis versus Hertz are examples of comparative advertising campaigns. Burger wars, Pepsi Challenges, and other brand comparisons are highly visible and have captured the attention of the media and consumers. This is an examination of the development of comparative advertising and conditions under which it can have more of an impact on marketing results.

Comparative advertising occurs when one brand provides a mention of another brand or brands in its advertising or in its related presentations and collateral materials. The comparison can be implied or can be specific to a particular brand or a set of brands.

The origin of comparative advertising can be traced to hundreds of years ago in England (Swayne and Stevenson, 1987). More recently, in 1930, Sears ran ads comparing its brand of tires to eight other national brands. Shortly thereafter, Plymouth ran advertising claiming that its cars were superior to Chevrolet and Ford.

It was not until 1971, however, that the number of comparative advertising campaigns in use increased substantially. This was due to a memo sent to the ABC and CBS Television Networks by Robert Pitofsky, the then Director of Consumer Protection at the Federal Trade Commission. In that memo, he indicated that consumers would benefit from explicit product and brand comparisons rather than indirect comparisons, which he believed might be misleading and deceptive. He encouraged the networks to aggressively seek out and accept comparative advertising campaigns.

Comparative advertising campaigns have been the source of substantial industry debates and scholarly research as to how and in what manner comparative advertising impacts marketing results. The reasons why comparative advertising might contribute to greater results have to do with speculation that comparative advertising receives more attention from consumers. First, comparative advertising might increase personal relevance to more consumers because the advertising names more than one

brand (Wilkie and Farris, 1975). In addition, comparative advertising tends to contain more information than noncomparative advertising.

Advertisers often have to make a decision as to when to use a comparative advertising format as opposed to a noncomparative advertising format. Two of the most comprehensive reviews of comparative advertising resulted in conclusions that comparative advertising is not always more effective than noncomparative advertising. The relative effectiveness of the two formats depends on a variety of variables or conditions or types of comparative advertising formats (Barry, 1993; Grewal *et al.*, 1997).

One consideration is the degree that the key brand attribute used as a basis of comparison is typical to a product category. When the attribute is typical, a noncomparative ad format is more persuasive. This is not the case, however, when the attribute is atypical (Pillai and Goldsmith, 2008).

Information-processing styles of the target audience is also a potential consideration in the effectiveness of a comparative advertising campaign (Thompson and Hamilton, 2006). When consumers use an analytical processing (information processing that is data driven and more focused on verbal retrieval and encoding), comparative ads are likely to be more effective than noncomparative ads. For consumers who tend to use an imagery-based processing style (information processing that is based more on nonverbal sensory representations), noncomparative ads are likely to be more effective.

Individual differences linked to information processing styles also factors into the reaction to comparative versus noncomparative advertising formats. For example, gender of the consumer may play a role in the reaction to comparative versus noncomparative advertising (Chang, 2007). Men experience greater brand evaluation involvement than women and, as such, comparative appeals lead men to experience higher levels of brand evaluations and purchase intentions. Women, on the other hand, experience a greater sense of manipulative intent generated by comparative appeals and, as such, women may record more negative ad and brand evaluations and reduced purchase intentions when exposed to comparative advertising.

In examining the potential effects of a comparative advertising campaign, the nature of the type of comparison may be important. One way of classifying a campaign is whether it is a direct comparison (e.g., “Honda is better than BMW”; “Miller is better than Bud”) or an indirect comparison (e.g., “Motrin is better than the leading brand”; “Nobody delivers faster than FedEx”). Research has demonstrated that the nature of the comparison may produce different results moderated by variables such as category size and the perceived variability of the category (Miniard *et al.*, 2006; Xiaojing *et al.*, 2007).

Given the wide variety of variables, there is not one single number that represents an overall assessment as to the effectiveness of comparative advertising campaigns. There are estimates that properly executed comparative advertising campaigns can boost sales by as much as 15% (MacArthur and Cuneo, 2007). Belief in the format has resulted in many marketers adapting comparative advertising claims and it has also generated substantial litigation and disputes concerning competitive claims.

It has been recently reported that disputed ad claims related to comparative advertising have risen 40% in 2008 compared to 2007 (Wasserman, Hein, and Wong, 2009). There are several sets of rules and regulations governing the use of comparative advertising claims that may result in claims by one company against another in the use of a comparative advertising campaign. Companies often use these standards as a basis for bringing complaints against competitors.

Standards and guidelines relevant to comparative advertising include those from the American Association of Advertising Agencies, the United States Federal Trade Commission, and the National Advertising Division of the Better Business Bureau. Media vehicles, including the television networks, usually have their own guidelines.

In addition, governmental bodies at all levels are likely to have rules governing the practice of the use of comparative advertising. Section 43(a)

(1) of the Lanham Act also provides a description of the conditions that a plaintiff must establish in seeking relief under the act. This act is often used as the basis for one party suing another party with the complaint noted as a violation of the Lanham Act.

a review of ethnic identity in advertising

Jeremy J. Sierra, Michael R. Hyman, and
Robert S. Heiser

WHAT IS ETHNIC IDENTITY AND HOW DOES IT RELATE TO ADVERTISING?

Ethnic identity entails self-identification as an ethnic group member, a sense of belonging to this group, and favorable attitudes toward this group (Phinney, 1992); it can be used as a way to overcome ad clutter and influence viewer responses to the traditional hierarchy-of-effects model in advertising. As ad impressions continue to mount, advertisers' difficulty in reaching their targeted consumers increases. One approach that may help overcome this difficulty entails the inclusion of ethnically resonant cues in ads, which may lead viewers to ethnically identify with such stimuli (Green, 1999); such methods have been shown to generate favorable viewer responses toward the ad and advertised brand (Sierra, Hyman, and Torres, 2009). Also, ads that depict ethnic characters, images, and values may lead ethnically resonant consumers to identify with the featured brand (Koslow, Shamdani, and Touchstone, 1994).

MEASURING ETHNIC IDENTITY IN ADVERTISING STUDIES

Ethnic identity is an enduring, underlying sense of connection to a social group (Tajfel, 1978). Strength of ethnic identity (i.e., strength of identity with one's ethnic origin (Deshpandé, Hoyer, and Donthu, 1986) or enduring association between one's ethnicity and sense of self (Forehand and Deshpandé, 2001)) can affect consumers' responses to marketing activities, shopping orientations, and product/service choices (Green, 1999).

Adolescents are more likely to believe and identify with ads laced with ethnically resonant cues (Appiah, 2001b). Relative to Blacks with weaker ethnic identities, Blacks with stronger ethnic identities see themselves as more similar to, and identify more strongly with, Black characters in ads (Appiah, 2001b; Whittler, 1989). Also, strong Hispanic identifiers prefer media that use Spanish verbiage (Deshpandé,

Hoyer, and Donthu, 1986), which suggests that strength of ethnic identity relates positively with tendencies to notice and identify with ethnically resonant ads.

Although careful in-depth questioning could reveal respondents' ethnic identity, expense and time issues preclude such questioning for large-sample empirical ad studies. Hence, researchers typically rely on standardized measures of ethnic identity. Specifically, researchers assess ethnicity in two ways: self-designated ethnicity – identifying oneself as belonging to an ethnic group – and felt ethnicity – how strongly one identifies with an ethnic group. Self-designated ethnicity is measured with a single, closed-ended question that asks respondents to indicate if they are Hispanic, Black, White, Asian, or Other. Felt ethnicity or strength of ethnic identity often is measured with the multigroup ethnic identity measure (Phinney, 1992). This measure, which applies to diverse samples and has proven reliable in previous studies, consists of five statements about ethnic attachment, feelings about ethnic background, happiness with ethnicity, ethnic pride, and sense of ethnic belonging. Responses to each statement are captured by a seven-point Likert scale anchored by *strongly disagree* to *strongly agree*.

REVIEW OF PREVIOUS EMPIRICAL STUDIES ON ETHNICITY AND ADVERTISING

Studies that qualified for review examined advertising-related effects of ethnic identification. In most studies, ethnicity was manipulated as an independent variable. Typically, respondents first read a magazine with filler and test ads. The test ads were identical in all regards but model ethnicity. Then respondents indicated their attitudes and/or purchase intentions toward the target ads and brands (e.g., see ATTITUDES; ADVERTISING MESSAGE APPEALS; ADVERTISING EFFECTIVENESS; INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?; INTERNATIONAL RETAILING). Many studies assessed ethnic identification with an ethnic-identity or perceived-similarity measure.

Studies were identified through (i) a keyword search of journal aggregator databases in busi-

ness, communications, education, and psychology (e.g., ABI/Inform, EBSCO, ERIC, Psyc-Info), (ii) a search for conference proceedings in Papers First and marketing society web sites (e.g., AMA, SMA), (iii) an online search for articles using keywords from uncovered articles, and (iv) listserv requests to business and psychology researchers for copies of published or unpublished manuscripts. Excluded studies examined effects of ethnic identification on nonadvertising outcomes, such as political affiliation, psychological assessments, and educational outcomes. Because few studies examined brand-related outcomes, such as brand prestige, brand loyalty, and brand awareness, those constructs were ignored.

Ultimately, 25 empirical articles, all published since 1971, were identified for review. In terms of studies per decade, the 2000s (11) and 1990s (8) are most prolific. The most common publication outlets were *Journal of Advertising*, *Journal of Advertising Research*, *Journal of Marketing Research*, and *Psychology & Marketing*, with four articles each, respectively; and, the most prolific authors were Deshpandé (6 articles), Whittler (3 articles), and several researchers with 2 articles (e.g., Appiah, Brumbaugh). Table 1 summarizes the 25 articles.

Ethnicities Studied. The most common ethnic cues in test ads portray Whites (75% of studies), Blacks (57% of studies), Hispanics (21% of studies), and Asians (14% of studies). These four ethnic groups are the biggest spenders and represent the largest population subgroups in the United States (U.S. Census Bureau, 2001).

Theoretical Frameworks Applied. Nine theoretical frameworks have been used to explain the effects of ethnic identity in advertising. Each framework, which offers unique explanatory power, may be encapsulated as follows:

- *Accommodation theory:* proposes that people generally like other people who share similar traits, which suggests, for example, that Black viewers will respond favorably to ads that use Black actors.
- *Cultural script theory:* emphasizes the portrayal of cultural themes and values, distinct to an ethnic group, through social communication, which suggests that the use of Spanish

or *Spanglish* verbiage in ads may resonant favorably with Hispanic viewers.

- *Distinctiveness theory:* posits that a person's distinctive or unique characteristics are more important to oneself than other local people's common traits. This theory suggests why Hispanics living in a Hispanic-minority-White-majority region are more likely to trust a Hispanic rather than White actor in an ad.
- *The elaboration likelihood model:* suggests that attitudinal responses stem from central route (i.e., high elaboration) or peripheral route (i.e., low elaboration) processes. As a result, Hispanic viewers may peripherally assess an ad for a Hispanic product when a Hispanic actor is used, and may centrally assess an ad for a Hispanic product when a White actor is used.
- *The heuristic-systematic persuasion model:* posits that message credence is evaluated either heuristically (i.e., casual evaluation) or systematically (i.e., scrutinized evaluation). For example, Asian viewers may systematically evaluate ads embedded with Asian cues because they trust an ethnically resonant source.
- *Identification theory:* suggests that people examine their similarity with environmental sources and then make similarity judgments, which may lead to Black viewers identifying more with ads that use Black actors rather than White actors.
- *In-group bias theory:* proposes that people favor in-group members, based on some characteristic, more than out-group members. As a result, Whites should evaluate White actors more favorably in ads with White and Asian actors.
- *Polarized appraisal theory:* suggests that in-group members will evaluate in-group stimuli less extremely than out-group stimuli. This theory implies that Hispanics will evaluate an ad with a Black spokesperson more thoroughly than an otherwise identical ad with a Hispanic spokesperson of comparable character.
- *Social identity theory:* posits that people's self-concept stems from their social and self-identities, which in turn contribute to self image and satisfaction. Hence, ads with

Table 1 Summary of ethnicity and advertising literature.

| Article | Research Question | ^a Overall Theory | ^b Ethnicity | ^c n; ^d Subjects | ^e Stimuli | Data Collected | Findings |
|--|---|-----------------------------|------------------------|--|---|--|--|
| Muse (1971) (<i>JMR</i>) | How are ads with only Black models perceived by White audiences? | No frame-work used | Blacks, Whites | 233; college students | Print ads for cigarettes, vodka, napkins, beer | Personal interviews; ads ranked on effectiveness and overall appeal | Ads with only Black models do not affect White consumers' perceptions of ad effectiveness or appeal |
| Bush, Gwinner, and Solomon (1974) (<i>JM</i>) | How do White consumers respond to Black models in in-store promotional materials? | No frame-work used | Blacks, Whites | 1344; White adults from SW US | End-of-aisle, POP displays with either all Black, all White, or mix of Black and White models | Observers recorded shopping behavior in supermarket | Whites respond similarly to point-of-purchase (POP) displays with all Black models, all White models, or a mix of Black and White models |
| Deshpandé, Hoyer, and Donthu (1986) (<i>JCR</i>) | Do different groups of Hispanics differ in their ethnic identification? | No frame-work used | Hispanics | 425; registered TX voters, 278 Whites, 147 Hispanics | None; mail questionnaire | Ethnicity; attitude toward institutions; AAD; brand loyalty; purchase influences | Relative to weak Hispanic identifiers, strong Hispanic identifiers more likely (1) to use Spanish language media, (2) to have more positive attitudes toward advertising, and (3) to purchase products advertised to Hispanics |
| Pitts <i>et al.</i> , (1989) (<i>P&M</i>) | How do Blacks and Whites respond to TV ads with cultural/ethnic cues? | No frame-work used | Blacks | 271; undergrads from W. and S. US; 82 Blacks, 189 Whites | Four 60-second TV ads targeted at Blacks | Personal values; ad rating; product usage rate | • Relative to Whites, Blacks respond more favorably to TV ads with Black actors |

embedded ethnic cues allow viewers in the targeted ethnic group to differentiate themselves from others, which reinforces their self-identity and uniqueness.

Collectively, these theoretical frameworks suggest that favorable advertising effects may ensue from ethnic identification with ads. They offer insights about greater responsiveness to ads that reflect resonant cultural values, increased trustworthiness of actors of similar ethnicity, and enhanced attitudes toward ads that imply cultural sensitivity to ethnic minorities; yet, researchers' reliance on these various frameworks does not explain the inconsistent findings on ethnic-identity effects in advertising. The frameworks most often applied to ethnic identity studies are distinctiveness theory (10 studies) and two studies each relied on identification theory, in-group bias theory, accommodation theory, and the heuristic-systematic persuasion model.

Standard Study Procedures. The most recurrent research question was response differences among ethnic groups – Blacks, Whites, Hispanics, and Asians – to ads with various ethnic cues. At least one ethnic cue appears in the test ads for all but two studies. Test ads depicted only two ethnic groups in 80% of studies, which may inhibit the generalizability of reported findings (Brumbaugh and Grier, 2006). Print or television ads were assessed in 92% of studies. The most common ethnic cues in test ads are targeted at Whites (77% of studies), Blacks (54% of studies), and Hispanics (22% of studies).

The mean sample size, which ranges from 62 to 648 (excluding an ethnographic study with 13 443 observations), is 239 people. The samples represent much of the United States where eight are Western, five are Southwestern, and three are Midwestern and Southern. Eleven studies rely on student samples – seven of undergraduate students, two of MBA students, and two of high school students – and eleven studies rely on adult samples. Thus, reported findings reflect responses of a roughly even mix of students and adults located throughout the United States.

In terms of the methods employed, typically, respondents were first exposed to advertising

stimuli, including filler and test ads. For the most part, test ads were identical in all regards but model ethnicity. Subsequently, responses were gathered about the ad, advertised brand, and/or model. Data pertaining to ethnic identity or perceived similarity with the model were often collected. Regarding the theoretical constructs examined, all studies assess some consumer attitudes (e.g., attitude toward the ad, attitude toward the brand), but only 10 studies measure intention to buy the advertised brand and only 3 studies measure ethnic identification with the ad. Only 1 study examines ethnic identification with the ad and its effect on purchase intentions of the advertised brand.

The most frequently used statistical method is ANOVA, which appears 13 times; the other methods used are regression analysis (7 times), MANOVA (4 times), discriminant analysis (2 times), and path analysis (2 times). Although 15 studies were published recently, 1994 or later, structural equation modeling is used only once.

Findings. The findings generally suggest that non-White consumers, relative to White consumers, are aware of and respond more favorably to ads with ethnic cues. In five studies that contrast weak versus strong ethnic identifiers, same-ethnicity actors in ads are more favored by the latter group. The four studies on the effect of ads with ethnic language (e.g., ads with Spanish words embedded) on same-ethnicity consumers suggest that Hispanics are more likely (i) to use Spanish-language media, (ii) to have more positive attitudes toward ads with Spanish verbiage, and (iii) to buy a product advertised with Spanish verbiage.

In-group members of an ethnic group evaluate ad stimuli more favorably when the actors/models are from the in-group rather than the out-group (Qualls and Moore, 1990). For example, relative to Whites, Blacks develop more positive affect toward ads with Black actors (Pitts *et al.*, 1989). Whites (Blacks) identify more with White (Black) actors than Black (White) actors, respond more favorably to ads with White (Black) actors, and are more likely to buy the advertised brand when White (Black) actors are featured (Whittler, 1989). Hence, ethnic consumers should identify with and respond more favorably to ads that target their

ethnicity. However, such assumptions are not always supported. Research shows that Whites respond similarly to point-of-purchase displays with all Black models, all White models, or an amalgamation of White and Black models (Bush, Gwinner, and Solomon, 1974). Using Asian models in ads favorably affects attitudes and purchase intentions toward the featured brand for both Asian and White consumers (Martin, Lee, and Yang, 2004). Asians, Blacks, and Hispanics identify most with ads that use Black actors, and Asians, Blacks, Hispanics, and Whites evaluate ads that use Black actors more positively than ads featuring White actors (Appiah, 2001b). These inconsistent findings cloud the role of ethnic identification in advertising and complicate decisions about ad design.

Are Study Results Artifactual? Although most ethnic identification studies relied on test ads evaluated by subjects in experimental or quasi-experimental settings, differences in method and research context may affect variance homogeneity across studies. Four possible sources of artifactual results are measurement type (i.e., single-item measure vs multi-item scale), study type (i.e., survey-based vs experiment-based), sample type (e.g., student or random adult), and media type (i.e., print vs TV).

In many cases, single-item measures can provide good assessments of concrete and well-accepted constructs, such as immediate purchase intention. However, single-item measures tend to reflect attitudinal and complex constructs less reliably, and lower reliability may cause less stable correlations. Conversely, typically more reliable and valid multi-item scales should yield more stable correlations.

Relative to surveys, experiments – by permitted control of extraneous factors that otherwise would interact with studied constructs – can generate larger effect sizes and imply inter-construct relationships that ultimately prove artifactual. Although the potentially interactive extraneous factors are infinite, many of them become known as a research stream matures.

Heterogeneous samples tend to attenuate effect size, especially in experimental studies (Fern and Monroe, 1996). Conversely, homogeneous samples may produce restricted responses

due to similar respondent backgrounds, incomplete self-identity, strong need for approval, and unstable group relationships. Although some marketing scholars have found that students respond more homogeneously, and other social scientists have found limited evidence that student samples yield larger effect sizes, a recent comprehensive meta-analysis suggests otherwise (Peterson, 2001).

Although previous research showed that television ads are more effective than print ads, recent studies suggest that television ads may only dominate print ads on ad awareness (Hansen, Olsen, and Lundsteen, 2006). Perhaps ethnic-identity effects are larger for television ads than for print ads because television's multichannel visual and auditory cues induce higher-quality thoughts and feelings for ethnically resonant ads.

The large number of theoretical frameworks and small number of published studies limited framework comparisons to no-stated framework, distinctiveness theory, and in-group bias theory. Studies with no-stated framework reported significantly higher effect sizes than in-group bias studies, which in turn reported higher effect sizes than distinctiveness theory studies. Type of measurement (single vs multi-item outcome scale) and study design (experiment vs survey) help to explain some heterogeneity in attitude toward the ad, model, brand, and purchase intentions of the advertised brand. As expected, ethnic identity effect sizes were larger in experiment-based than survey-based studies. Studies with respondents from only two ethnic groups (e.g., Hispanic and Caucasian or Black and Caucasian) produced lower effect sizes than studies with more diverse samples of three or more ethnic groups. Surprisingly, single-item measures yielded larger correlations than multi-item scales, perhaps due to the larger variety of multi-item scales used in ethnic identity studies.

The sample-weighted estimates of ethnic identity's influence on all advertising outcomes were medium-sized effects with composite r ranging from 0.18 to 0.30. Five studies reported small effect sizes ($r < 0.10$) and none reported large effect sizes ($r > 0.50$). All correlations between ethnic identity and attitude toward the ad, attitude toward the model, attitude toward

the brand, and brand purchase intention were significant ($p < 0.05$).

Although methodological heterogeneity accounts for some unexplained variance in ethnic identity research, the relatively few studies with significant findings makes this result tenuous. Although researchers continue to debate the merits of student samples, we found no differences in studies with student versus nonstudent respondents. In the many experiment-based studies, researchers were able to maintain high internal validity and boost statistical power. As expected, questionnaire-based studies produced lower ethnic identity effect sizes. Although it does not account for response differences among ethnic groups, our analysis confirms that ethnic identity effects are activated in ethnic groups even if they are not portrayed in test ads. Thus, generalizability concerns about ethnic identity studies in advertising may include both the limited range of test stimuli (Brumbaugh and Grier, 2006) and respondent samples.

DISCUSSION

Consumers relate to ethnically resonant ads by developing, maintaining, and enhancing their social identification and attachments to the featured brands. The results from our review of the literature indicate that ethnic identity influences all elements of the advertising hierarchy-of-effects, producing the largest effect on attitude toward the brand. The regression analysis of unique variances shows a direct linkage between attitude toward the model and attitude toward the brand. The moderation analysis suggests methodological artifacts; for example, ethnic identity effects are larger in experiment-based than survey-based studies. In addition, three studies with single-item measures produced higher correlations than studies with multi-item scales, especially with attitude toward the ad. Two of these studies examined attitude only toward the ad, and thus may have captured overall attitudes within a single-item attitude toward the ad measure.

Managerial Implications. Research shows that consumers are more likely to notice and respond favorably to an ad if it contains ethnically resonant cues (e.g., Qualls and Moore, 1990; Whittler, 1989); thus, advertisers should benefit from

developing ads with such cues. Advertisers could accentuate same-ethnicity models' skin color, facial features, demeanor, verbal expression, and apparel styles, like McDonald's has done with its successful Hip Hop *i'm lovin' it* ad campaign targeted at Hispanic and Black customers. With their growing popularity and efficacy, the physical traits of animated spokescharacters (e.g., skin color, hairstyles, facial features) could be adapted to targeted ethnic viewers. Ethnic identity expands beyond actors; hence, durable goods producers can foster ethnic identification via ads that focus on country of origin. For example, ads targeting Asians can stress that some product components were produced and/or the product was assembled in China. Moreover, firms can appeal to Hispanics with ads that combine Spanish and English (i.e., Spanglish) without fear of backlash from Whites (Koslow, Shamdassani, and Touchstone, 1994).

Service providers can foster ethnic identification within targeted groups via ads that celebrate annual ethnic-related occasions, such as Saint Patrick's Day (e.g., Bennigan's Grill & Tavern offering green lagers), Cinco de Mayo (e.g., Chili's Bar & Grill promoting Mexican beer), and Black History Month (e.g., Barnes & Noble bundling Black literature). To appeal to Hispanics, firms could place ads with Hispanic actors in magazines targeting Whites. Although firms may believe that Hispanic actors in ads can induce negative attitude toward the ad and brand in White readers (Qualls and Moore, 1990), previous research shows that this belief is false (Whittler, 1989). Hence, ads with Hispanic actors will gain the attention of Hispanic readers without alienating White readers.

Future Research. Because ethnic identity significantly influences all stages of the hierarchy-of-effects model, future studies should explore the indirect and mediation pathways between advertising and ethnic identity, particularly within different advertising contexts with various products. Also, the relative efficacy of different types of ad cues (e.g., slogans, argot) to induce ethnic identification is unknown. Although our meta-analysis uncovered moderating factors that explain some variance in ethnic identity effects, further research is needed to answer questions like "Does the tagline or

actor's appearance in an ad create stronger ethnic identity effects?"

globally integrated marketing
communications

Shintaro Okazaki

DEFINITION AND CONCEPTUALIZATION

The concept of globally integrated marketing communications (GIMC) was first introduced by Okazaki, Taylor, and Zou (2006) in their work on advertising standardization strategy by American and Japanese multinational corporations (MNCs) in the European Union. They refer to GIMC in the traditional sense of communicating a single message through a multiple marketing communication mix in various media across countries, and conceptualized it as a key element of global strategic orientation.

However, the ability to engage in GIMC depends not only on the firms' strategic orientation, but also on the availability of agencies that operate on a global basis. In this regard, the literature suggests that the growth of "mega-agencies" has changed the structure and operational practices of IMC. Most MNCs now seek simple but self-consistent solutions for global planning and implementation facilities in multiple markets. Agencies also believe that the full-service advertising agency will remain the principal source of creative and media services (Tharp and Jeong, 2001). The future use of standardization is more likely to be increased by these internal and external pressures than by economic benefits or the emergence of global consumers (Duncan and Ramaprasad, 1995). However, Gould, Lerman, and Grein (1999) point out that large, US-based advertising agencies are likely to assume that "the main issue of global communications is not thought to be standardization versus adaptation, per se, but rather organizational coordination which recognizes and encourages global strategies while working with local managers and markets" (see page 13). Such integration seems possible only for those "mega-agencies" that hold a wide variety of international advertising accounts in diverse regions (Moriarty and Duncan, 1990). In addition, the proliferation of the Inter/intranet, the digitalization of traditional media, and mergers and acquisitions among media companies have

enabled agencies to practice media planning on a global basis (Okazaki, 2005).

In this vein, Tharp and Jeong (2001) provide an astute observation on global network communications agencies. They argue that the advertising agency's perspective is very relevant to the global integration of marketing communications, because it is unlikely that MNCs make the very technical decisions such as the adoption and planning of, for example, global websites. Tharp and Jeong argue that "Global clients want 'one-stop access' and global planning and implementation capabilities from their agency partners", and these agencies are particularly helpful in predicting consumer characteristics in new markets and new media. In addition, larger agencies are expanding their service portfolios horizontally into areas requiring more specialized expertise, by merging interactive advertising, strategic brand planning, and direct marketing (Tharp and Jeong, 2001). This implies that such large agency networks may have consolidated websites in different parts of the world. Therefore, the presence in Europe of US-based multinational agencies, such as Omnicom Group (which includes *BBDO*, *DDB Needham*, *TBWA*, etc.) and Interpublic Group (which includes *Ammirati Puris Lintas*, *The Lome Group*, *McCann-Erickson*, etc.) may have substantially influenced the GIMC of American MNCs.

More evidence of the emergent global mega-agency can be found in the literature on the standardization of corporate visual identity from a UK perspective. Melewar and Saunders (1999) examined the factors influencing the international standardization of corporate visual identity among 40 British MNCs that operate in Malaysia. They found that local agencies play a minimal role in the development of corporate visual identity for the firms. Instead, British MNCs tend to use UK-based agencies or the in-house designers at their corporate head office. This appears to support our thesis in that the larger firms that operate in international markets centralize their marketing communication strategy, which is consistent with our conceptualization of GIMC.

2 globally integrated marketing communications

THE PRIMARY BENEFITS OF GIMC

The primary benefits of GIMC can be summarized as follows:

1. The creation of a uniform brand image across markets.
2. Lower costs in developing and maintaining marketing strategy and programs.
3. The execution of common campaigns to cross-border segments that share similar preferences.

Some may argue that the adoption of GIMC is still limited in the sense that the integration of the mix of various marketing communication strategies and programs is a rather complicated task (Kitchen and Schultz, 1999). For example, the most visible element of marketing communication, advertising, is relatively easier to coordinate across borders, compared with other elements, such as sales promotion or direct marketing. Nevertheless, GIMC is an increasingly important issue, as it is directly related to the creation of a strong and uniform brand image across markets. By establishing consistent logos and symbols, sponsorship, events and experiences, and Internet website, the brand image – especially in terms of awareness, uniqueness, and association – can be similarly perceived in multiple markets. Undoubtedly, this leads to the strengthening of the brand equity.

In addition, the worldwide coordination of marketing communication would decrease the production costs, because relevant information about implementation and expertise can be shared among foreign subsidiaries and headquarter(s) via the networks of global mega-agencies (Tharp and Jeong, 2001). In the same token, the costs would be lower when they share advertising campaign or commerce globally (Zou and Cavusgil, 1996). Currently, the prolonged worldwide economic recession has made it imperative that firms seek a more cost-effective communication strategy as many companies are cutting their marketing communications budget (Goldsmith, 2009). The digitalization of media planning and execution is making this coordination task more realistic and feasible than it was in the past (Okazaki, 2005).

Finally, the availability of integrated media enables firms to seek commonly attractive and persuasive campaigns to cross-border segments. The literature suggests that there is a global youth segment that shares similar lifestyles, habits, and preferences in many industrialized countries. For example, the entertainment industry – especially gaming, is an example of a cross-border segment that can employ similar promotional campaigns with almost identical stimuli and messages.

THEORETICAL PERSPECTIVES

Standardization of global marketing. One of the reasons why firms should integrate their marketing communication mix across borders is related to the global marketing strategy (GMS) of international firms. In this regard, Zou and Cavusgil (2002) presented a broad conceptualization of a theory of GMS that incorporates eight dimensions, including product standardization, promotion standardization, distribution standardization, pricing standardization, and other dimensions related to the global coordination of value-adding activities. Building on industrial organization theory and a resource-based view of the firm, the GMS theory contends that the fit between (i) a company's marketing strategy and (ii) its external environment and its internal organizational resources determines the company's performance in the global market. When external market factors and internal organizational characteristics are conducive to global marketing, a more globalized marketing strategy, such as employing a higher degree of standardization and integration, will positively impact a company's strategic and financial performance globally. Using survey data, Zou and Cavusgil (2002) offered empirical support for the GMS model.

Among the various strategies of GIMC, probably one of the most visible examples is the standardized advertising of global brands. For over 50 years, the topic of standardization of advertising has received considerable attention in academic literature, and it has developed into one of the most researched topics in international advertising (Agarwal, 1995). The issue of standardization arises from the concept of global marketing which notes the desirability and feasibility of the use of a uniform marketing

mix (4Ps – product, price, place, and promotion) across international markets (Szymanski, Bharadwaj, and Varadarajan, 1993). Among them, advertising has been examined more often than the other elements. A “standardized” approach is the use of uniform messages with no modification of headings, graphics, or copy, except for translation, in international markets (Onkvisit and Shaw, 1987). This school of thought argues that consumers anywhere in the world are likely to share the same wants and needs (Elinder, 1961; Levitt, 1983). On the other hand, a “localized” approach asserts that consumers differ from country to country, and advertising should thus be tailored according to the culture, media availability, product life cycle stages, and industry structure (Synodinos, Keown, and Jacobs, 1989). Between these two extremes, a third school of thought states “think global/act local”, as the appropriateness of standardization depends on economic similarity, market position, nature of the product, environment, and organizational factors (Jain, 1989).

In the 1970s, empirical evidence indicated a high degree of localization owing to increasing nationalistic forces as well as well-publicized advertising blunders during the 1960s (Agrawal, 1995). This trend reversed toward standardization in the 1980s along with the rapid rise of multinational advertising agencies. During this period, a series of content analysis studies attempted to identify cross-cultural differences between Japanese and American advertising (Belk, Bryce, and Pollay, 1985; Mueller, 1987).

In the 1990s, localization appears to have remained popular among MNCs operating in the various regions of world markets. Harris (1994) found that 69% of 38 MNCs (19 Americans and 19 Europeans) standardized their advertising campaigns to some extent in European markets, while the rest of the sample localized. However, only 8% of the sample used totally standardized advertising, providing “little evidence of any widespread practice of standardized pan-European advertising campaigns” (Harris, 1994). Kanso and Nelson (2002) found that 62% of 193 firms studied (both American and non-American subsidiaries) in Finland and Sweden used localization, placing strong emphasis on local cultures. Similarly, Samice *et al.* (2003) found that MNCs operating in

Southeast Asia tend to localize advertising. They examined 113 firms in Hong Kong, the Peoples’ Republic of China, Taiwan, and Singapore, and found that environmental and economic factors are the primary drivers of this tendency.

In a recent study, Okazaki, Taylor, and Zou (2006) proposed a model of advertising standardization consisting of organizational, environmental, and strategic factors as antecedents, and advertising effectiveness, financial performance, and strategic performance as consequences. Given that advertising standardization is a component of the GMS, they applied Zou and Cavusgil’s (2002) model, which provides a solid theoretical foundation for investigating the drivers and consequences of advertising standardization. On the basis of the data collected in several European Union member states (United Kingdom, France, Spain, Germany, and the Netherlands), their findings suggest that the recent economic unification in Europe has contributed to the acceleration of cross-market homogeneity in consumer characteristics, market structure, media availability, and competitive intensity, which, in turn, closely relates to the degree of standardization of advertising and its effectiveness.

Global brand positioning theory. Another relevant theoretical framework for GIMC is global brand positioning theory. Drawing on global consumer culture theory, Alden, Steenkamp, and Batra (1999) have suggested that “global consumer culture positioning” (GCCP) will resonate with increasingly global segments of consumers. The basic idea is that a gradual trend toward cultural convergence in some (but not all) respects makes standardization more feasible than in the past, but that some types of marketing approaches can be standardized more easily than others. In GCCP, the brand is defined as *a symbol of a given global culture, which consumers may purchase to reinforce their membership in that segment*. Obviously, from a GIMC perspective, the existence and prevalence of a global consumer culture is a good reason for firms to integrate, concentrate, and coordinate their marketing communication mix across countries.

Specifically, Alden, Steenkamp, and Batra (1999) argue that emotional and image-based

advertising messages or a “soft-sell approach” is more suitable than hard-hitting and fact-based advertising appeals or “hard-sell approach” for GCCP, because “global consumer culture is an emerging and rapidly changing phenomenon, with differing sets of signs in differing global segments. Advertising that uses this “soft-sell” approach will be more effective because it communicates in a subtle, indirect, and abstract fashion” (Alden, Steenkamp, and Batra, 1999, p. 79). The authors classified the overall sales appeal of an advertisement by labeling two contrasting approaches: the “soft-sell” approach (image-oriented content that does not emphasize reasons to buy, but rather conveys general associations with the brand) versus the “hard-sell” or direct approach. It is of interest to note that their research suggested that the features of the “soft-sell” approach (subtlety, implicitness, and abstractness) are more suitable than the “hard-sell” approach for a global consumer culture positioning strategy.

In the study, the authors analyzed a total of 1267 advertisements from seven countries. In total, 284, or 22.4%, of the advertisements were found to employ a GCCP. More than half (56.4%) of those examined used a “soft-sell” approach. GCCP was compared with local consumer culture positioning (LCCP), which associates the brand with the culture of the local consumer. This strategy resonates with some consumer segments because they more readily identify with local attitudes, values, and lifestyles. Acknowledging that the 1990s represented a relatively early stage of the global diffusion of consumer culture, Alden, Steenkamp, and Batra (1999) proposed that LCCP, which reflects local values, was used more frequently than GCCP, and indeed, their findings strongly support this hypothesis.

On the basis of the above logic, it would follow that there is considerable opportunity to standardize advertising strategies and perhaps some aspects of execution. On the basis of prior evidence from Alden, Steenkamp, and Batra (1999), it follows that it may be possible to obtain a positive reaction to “soft-sell” messages across a wider range of cultures, while it is probably more difficult to realize success with standardized “hard sell” messages.

FACTORS INFLUENCING GIMC

Given the theoretical bases discussed above, it seems reasonable to conceptualize GIMC as an ultimate extension of global marketing – in particular, advertising – standardization. The rationale for this is that the goal of GIMC is to create a uniform brand image in a cost-effective way that can be appealing to cross-border segments. In a strict sense, standardization may differ from the coordination of IMC in that some of the communication mix, for example, personal sales or sponsorship, cannot be standardized due to local conditions, but it is a reasonable (and feasible) starting point in a practical sense. In this light, the literature seems to suggest that there are three factors that may influence the global integration of marketing strategies of firms in multiple markets: environmental factors, strategic factors, and organizational factors. In the following sections, we discuss and extend these factors in terms of GIMC.

Environmental factors. The environmental factors include *customer similarity*, *market similarity*, *similarity of advertising infrastructure*, and the *level of competition*, all of which appear to affect the firms’ willingness to implement the worldwide integration of their marketing communication mix. Collectively, we refer to these four constructs as environmental factors, as they all relate to the external environment of the cross-national markets served.

As defined here, *customer similarity* refers to the degree to which consumers in the markets served have similar lifestyles, preferences, and tastes. Cultural factors such as tastes and preferences can have a substantial impact on the viability of standardization (e.g., Jain, 1989; Laroche *et al.*, 2001; Onkvisit and Shaw, 1999). Here, a critical question relates to whether consumers exhibit a similar preference for the standardized messages regardless of culture to which they belong. It has long been argued that advertising messages should be congruent with the values of local culture (Boddewyn, Soehl, and Picard, 1986; Belk, Bryce, and Pollay, 1985; Lin, 2001; Mueller, 1987). Further, a number of empirical studies have found that advertisements reflecting (some) local cultural values are more persuasive than those that ignore them (Taylor,

Miracle, and Wilson 1997; Han and Shavitt, 1994). Thus, it is also important to examine the factors related to a culture's impact on GIMC.

Market similarity refers to the degree to which the countries served by the MNC have similar levels of economic development. In the context of GIMC, *market similarity* reflects both the extent to which managers view the individual countries as economically similar, and their perceptions of the impact of economic unification on the similarities in the overall market. As with *customer similarity*, firms are more likely to coordinate their marketing communication mix if they view the cross-national markets they serve as having similar levels of economic development (e.g., Duncan and Ramaprasad, 1995; Harvey, 1993; Samiee *et al.*, 2003).

It has been seen that the similarity of the *advertising infrastructure*, including the availability of similar media with similar costs, the presence of similar laws, and access to market research firms, also influences the level of GIMC in a market (Samiee *et al.*, 2003; Taylor and Raymond, 2000). In general, when advertising infrastructures are similar across markets, it has been found that it is more feasible for companies to engage in the global integration of their marketing communication (Jain, 1989).

The final environmental factor is the *level of competition*, which refers to the degree to which the markets served are sought after by competitors. The *level of competition* can affect the propensity to use standardized advertising messages (Samiee *et al.*, 2003; Yip, 1995). In settings where competitive conditions are intense, the coordination and integration of the various components of the marketing communication mix would make sense because it would build a consistent image that would contribute to gaining a competitive advantage, or to responding to a competitor that has built a consistent image. It should be noted that the level of competition, as defined here, does not refer to the firm's relative competitive position in each market. It is, rather, the overall degree of competition that the company faces in those markets in which it operates.

Strategic factors. The literature of marketing standardization has suggested that, in addition to environmental factors, various internal strategic

factors influence the level of standardization at which a firm engages (e.g., Cavusgil and Zou, 1994; Duncan and Ramaprasad, 1995). By the same token, we propose three strategic factors, namely *global strategic orientation*, *perceived cost savings*, and *cross-border segmentation*.

The idea of a firm having a *global strategic orientation* has received considerable attention in the marketing strategy literature. In particular, Zou and Cavusgil's (2002) GMS perspective suggests that standardization of advertising is a key characteristic of firms that have a global orientation. As defined by Zou and Cavusgil (2002, p. 46), global orientation refers to "the organization-wide emphasis on success on a worldwide basis rather than on a country-by-country basis." Global orientation is part of a firm's corporate culture, and it can be viewed as a key organizational resource because it is a potential source of competitive advantage (Levitt, 1983; Ohmae, 1989; Zou and Cavusgil, 1996). Recent research evidence suggests that global strategies have a higher potential for effectiveness than they had previously. For example, Zou and Cavusgil (2002) found that firms employing a GMS achieve, on average, higher strategic and financial performance than those that do not. Moreover, Steenkamp, Batra, and Alden (2003) found that the perceived "globalness" of a brand has a positive impact on consumer perception of the brand's quality and prestige.

The second strategic factor in our model, *perceived cost savings*, refers to the firm's belief that GIMC will lead to cost savings in the production and execution of marketing communication mix programs. If the firm has a desire to save costs through GIMC, it follows that it will engage in a relatively high degree of integration. In the marketing literature, numerous authors have argued that standardization is associated with substantial cost savings. Duncan and Ramaprasad (1995) found that most of the managers surveyed did not believe that cost savings alone were a sufficient reason to justify standardized campaigns, but it is quite likely that firms that are confident that they can develop effective advertising across markets view cost savings as a key advantage. The same logic could apply for the adoption of GIMC.

Another concept related to Zou and Cavusgil's (2002) GMS perspective is the firm's belief that *cross-border segmentation* can be effective. *Cross-border segmentation* is defined as *the extent to which firms believe they can and should target consumers with similar characteristics across markets*. Several researchers have suggested that MNCs should engage in *cross-market segmentation* (Hassan and Katsanis, 1994; Miller, 1998; Shermach, 1995). A study by ter Hofstede, Steenkamp, and Wedel (1999) also suggested that cross-market segmentation could be successfully applied to the market for yogurt in Europe. To the extent that marketers engage in targeting groups on criteria that cut across borders (e.g., age, lifestyle), we predict that they will be more likely to integrate IMC globally in order to reach their customers.

Organizational factors. One of the organizational factors that has received widespread attention is the *level of control* that the parent firm has over subsidiaries, and its impact on their willingness to adopt headquarters-led strategic orientation (Samiee *et al.*, 2003). For example, it is widely believed that when control is centralized at the MNC's headquarters, more common marketing strategies will be used (e.g., Duncan and Ramaprasad, 1995; Laroche *et al.*, 2001). The basic idea is that centralized decisions help to ensure that overall corporate goals are met. If these goals involve GIMC, it is much easier to implement them centrally than it would be if local subsidiaries were granted autonomy. For example, an empirical survey by Duncan and Ramaprasad (1995) confirmed that firms with a higher degree of control emanating from headquarters were more prone to engage in standardized advertising. Similarly, Laroche *et al.* (2001) found that those MNCs with highly centralized control engaged in more standardization.

The *size of the firm* is defined here as *the subsidiary's annual sales volume*. As Samiee *et al.* (2003) noted, prior research on international business suggests that larger firms are more likely to expand into foreign markets and to have a standardized worldwide image. Additionally, work on entry to foreign markets suggests that large firms prefer wholly owned subsidiaries, partly to ensure that their general corporate strategy is carried out uniformly (Erramilli and Rao, 1993).

At the subsidiary level, it can be argued that it is likely that larger firms will also be more prone to engage in closely coordinated activities

Several researchers have found that *level of international experience* is also helpful to firms in planning an international strategy. Cavusgil and Zou (1994) found empirical support for the idea that more experienced exporters have higher levels of success in international markets. Additionally, Zou and Cavusgil (2002) found a significant link between the firm's *level of international experience* and its use of a GMS, including a global promotional strategy.

CONCLUSION

The increasing availability of global mega-agencies enables firms to adopt the global integration of diverse marketing communication mixes across border and facilitates the development of globally integrated marketing communication or GIMC. GIMC is defined as *an ultimate extension of global marketing standardization*. In doing so, two theoretical frameworks are explained: GMS theory and global brand positioning theory. Wherever possible, more and more firms are interested in coordinating their marketing communication mix in multiple markets in order to create a uniform and strong brand image and ultimately to increase brand equity. Also, such global integration decreases costs in developing and maintaining marketing strategies and programs, and eases the execution of common advertizing campaigns to cross-border segments that share similar preferences.

database marketing

John A. McCarty

INTRODUCTION

Database marketing involves the analysis of customer transaction data, along with other customer information (e.g., demographics), to segment customers (*see* MARKET SEGMENTATION AND TARGETING), and to develop marketing strategies (*see* MARKETING STRATEGY) to some or all of those segments. A key aspect of this description is that database marketing almost always involves the analysis of transaction data, either alone or with other kinds of customer data. Transaction data include information about the actual purchases made by consumers, such as when a purchase was made, the assortment of items that were purchased, and the total amount that was spent during a particular purchase. Thus, database marketing is generally employed by marketers having access to such information about individual customers, including catalog marketers, retailers, credit card companies, and others that engage in direct contact of one sort or another with customers. Nonprofits (e.g., charities, associations) have also utilized database marketing. A charity, for example, has information about donors, including how much they have donated over the years, the amount of their largest donation, and the number of times they have donated.

Among marketing firms, direct marketers (e.g., L.L. Bean) were the first to employ database marketing techniques. Their earliest efforts were largely informal in that direct marketers tended to note the patterns and preferences of their customers and to utilize knowledge of these in their marketing to repeat customers (Baier, Ruf, and Chakraborty, 2002). As the number of customers for these firms grew to a level that would make such informal methods impractical, computers and analytical procedures were developing that could automate the tracking of customer behavior.

Today, database marketing involves a number of analytical procedures, both basic and sophisticated, that enable direct marketers to track the behavior patterns of their customers. There has also been an increase in the use

of database marketing by firms that are not traditional direct marketers, such as credit card providers, automobile rental agencies, brick and mortar retailers, casinos, and hotel chains. Virtually any firm that routinely captures transaction information as part of the way it does business can engage in database marketing.

DATABASE MARKETING AND TRADITIONAL MASS MARKETING

Firms that engage in database marketing differ from most traditional mass marketers that produce packaged goods (e.g., ketchup, paper towels) in two important and related ways. First, database marketers have individual customer-level information. Since they generally deal with their customers in a direct manner, they can identify their customers individually, including customers' names and addresses. Second, database marketers have the information about individual customer's transactions with the firm. That is, every time a specific customer makes a purchase, the marketer collects information about how many different items were purchased, how many of each of these items were purchased, how the customer made the payment (i.e., credit or check), and so on. This individual level information allows database marketers to serve very small segments of their customers and to personalize and customize their marketing efforts to individuals. Furthermore, given that they have the actual transaction data of customers, database marketers can segment and develop strategies based on the actual behavior of customers rather than on characteristics such as demographics.

What database marketers can do with these data contrasts with the abilities of traditional mass marketers. A typical mass marketer, like the ones that produce packaged goods, sells to consumers through intermediaries. Mass marketers do not know the names or characteristics of their individual customers and have no information about the specific purchases, as these transactions occur in supermarkets, drugstores, and/or mass merchandisers. Mass marketers can make inferences about the characteristics of their customers based on survey research and other marketing research studies. Although such studies can provide

2 database marketing

these marketers with insights about their typical consumer, they cannot tell them about the behaviors of individual consumers. Survey research may inform a mass marketer that the consumers who purchase its brand are generally of a particular age group and gender. Other types of marketing research may tell the mass marketer such things as on what occasions consumers typically use the product, in what quantities they use it, or even how they feel about it (e.g., the pros and cons of its brand relative to other brands). Although this information is extremely valuable to mass marketers in the development of their marketing strategies to the broad segments that they serve, it cannot provide them with ways of marketing to specific customers.

Although it may seem that database marketers have enormous advantages over mass marketers, the ability to market to individual customers comes with certain costs. Developing and maintaining a customer database can be a costly activity. Designing and implementing marketing strategies to small segments of customers and developing customized promotional materials can be very expensive. Therefore, the revenues that firms employing database marketing techniques receive must cover the costs of these efforts. For the vast majority of traditional marketers, the selling of their products through mass marketing outlets such as supermarkets makes sense, given their profit margins. Moreover, it is convenient for most consumers to buy their packaged goods in one place (e.g., local supermarkets); therefore, consumers are generally not interested in purchasing such items as toothpaste, canned beets, and toilet paper in a direct way from the different marketers of these goods. Therefore, for both the firms producing most packaged goods and the consumers of those goods, the way these things are bought and sold makes reasonable sense.

Considering marketing activities at a broad level, it can be said that database marketers and traditional mass marketers engage in similar activities; that is, both types of marketers engage in segmentation and the development of marketing strategies to serve these segments. The crucial difference is the kind of information that is used to engage in these marketing activities. Database marketers have information

that allows them to segment on the specific behaviors of their customers and to develop customized strategies to narrow segments or even to individuals. Traditional mass marketers have information from marketing research that allows them to segment on variables that relate to consumption (e.g., demographic information) and develop strategies based on the inferred behavior of large segments of consumers.

QUESTIONS THAT DATABASE MARKETING MAY ADDRESS

As noted, database marketing involves the quantitative analysis of customer transaction information in an effort to engage in marketing strategy and tactics with respect to those customers. Three examples aid in understanding the range of questions that database marketing may address.

A common issue for a database marketer is how to segment its database such that it can identify the very best customers, those that it may be able to convert to this top group of customers, and even those toward whom it may want to discontinue marketing efforts. (Hughes, 2005). The very best customers (gold customers, according to Hughes terminology) are those who are doing a lot of business with the company and these are the ones on which the marketer may want to spend more customer service dollars. Those who are just below gold customers are the ones that the company may want to market to heavily, with an eye toward increasing their business to the level of gold customers. At the other extreme, there are customers who do very little business with the marketer. The revenues obtained from these customers may be so little as to not really justify any marketing effort by the firm. Analysis of the revenues obtained from different customers in the data file and their patterns of transactions can help database marketers place their customers in these various segments.

A very common question for catalog marketers is, "who among our total customers should receive an upcoming mailing?" This sort of question is a very serious one for marketers relying on the mail to conduct business in that the postage rate generally makes mailing to the total customer file cost prohibitive. Even if the cost is much less than a dollar per piece, mailing

to a file of tens of thousands of customers is an expensive proposition when the typical response rate is less than 5% for a single mailing. This problem is a segmentation and targeting issue in that a marketer would like to mail to the people in the database who are the most likely to respond to the mailing. Identifying those most likely to respond to a particular mailing from transaction variables in the customer data file is a typical database marketing problem. Analysis of the customers who have responded to similar mailings in the past compared with those who did not is one way of evaluating who should receive an upcoming mailing.

A different sort of database marketing effort is in the area of cross-selling. Cross-selling involves efforts toward marketing one product or service to customers currently purchasing other products or services from a marketer. The nature of the information in a customer data file allows marketers to evaluate cross-selling opportunities. Marketers can evaluate the pattern of purchases for the typical customer and determine if there are different products that customers tend to consistently buy together. A supplier of clothing, for example, may note that customers who buy dress shirts from it also tend to buy ties. A cross-selling opportunity would be to identify those customers who have been buying shirts, but not ties, and attempt to market ties to these customers through a promotional effort.

DATABASE MARKETING AND DATA MINING

Database marketing is the application of data mining techniques in the context of marketing strategy and tactics. According to Berry and Linoff (2000), "data mining is the process of exploration and analysis, by automatic or semi-automatic means, of large quantities of data in order to discover meaningful patterns and rules (p. 7)". Data mining, therefore, can be thought of as an approach to understanding and interpreting data; when marketers engage in mining their customer data, it is database marketing. However, data mining has many applications—not only marketing or business applications but also in such diverse areas as health care, engineering, the military, and public policy, to name a few. Data mining is applicable to any situation where there is an enormous

amount of quantitative information and there is belief that understanding the patterns of the data will provide useful insights.

Data mining techniques tend to be data driven rather than hypothesis driven (*see* HYPOTHESIS TESTING RELATED TO DIFFERENCES – PARAMETRIC TESTS). In other words, the typical data mining analytical procedure searches for patterns and relationships in the data. In contrast, hypothesis-driven research begins with beliefs about the patterns that may exist in the data. The data are used to test the viability of a hypothesis. The advantage of the data-driven approach is that one need not have a priori assumptions about the relationships; one is searching for any patterns that may exist. Therefore, one may discover relationships that were not anticipated and these serendipitous findings may prove to be meaningful and useful to the database marketer. The very real danger with such data-driven approaches is that one may be capitalizing on chance relationships in the data. Without a hypothesis based on sound theory, it is far more likely that one will find relationships because of the search for any relationship; some of the found relationships may exist because of chance occurrences rather than meaningful and robust relationships that will maintain across time. It is therefore critical that database marketers understand this important aspect of their analysis approach and take steps to evaluate the reliability of their findings.

DATABASE MARKETING AND RELATIONSHIP MARKETING

Database marketing is closely associated with relationship marketing (*see* CUSTOMER RELATIONSHIP MANAGEMENT). Although definitions of relationship marketing vary from very narrow views to broad conceptualizations (Parvatiyar and Sheth, 2000), a primary focus of relationship marketing is on the long-term interactions between buyers and sellers rather than on the individual transaction event. So, for example, an automobile dealership approaching its business in a relationship manner will think in terms of servicing its customers' transportation needs over years rather than the sale of a car on a specific day. This would entail a consideration of postsale services and attention to the customers

such that they will buy future cars from the dealer. Those promoting relationship marketing argue that such long-term focus will be beneficial to both the buyer and seller.

Direct marketers were some of the earliest marketers to think in terms of long-term relationships with their customers. To a great extent, direct marketers' focus on the long term was out of necessity. For a typical mailing, the postal costs are very high relative to the revenues resulting from that specific mailing. This cost-to-revenue relationship dictates that direct marketers think in terms of the long-term profitability of the customers acquired from the mailing in order to justify the mailing. An illustration will help make this point. Imagine that a marketer is going to do a mailing to 50 000 people. The cost of the mailing is \$0.75 per piece; the total mailing cost is therefore \$37 500. The response rate is 2.5% (a typical response rate for a cold mailing), which amounts to 1250 people responding. The average revenue per response (with all costs except for mailing subtracted) is \$30. So, the total revenue before the mailing costs are subtracted is \$37 500. Thus, it appears that the marketer would make no money from the mailing, to the extent that it thinks only in terms of this mailing and the revenues received from this mailing. If the direct marketer thinks about the long term, it will consider how much revenue that the 1250 responders will generate over time. This revenue will not only be in terms of those responders' future purchases but also the revenues generated by people they may refer to the marketer. These 1250 people may generate a lot of profits for the company over the next several years, to the extent that the direct marketer practices sound relationship marketing. This way of thinking relates to the concept of the lifetime value of the customer (*see* CUSTOMER LIFETIME VALUE (CLV)). The lifetime value of a customer is the net present value of the revenues that will be received from a customer over a period of time in the future (usually 3–5 years). In this example, the direct marketer may have only received \$30 in revenues from the average customer for this mailing, but its lifetime value analysis may estimate that it will receive hundreds of dollars from the average responder when considered across time.

Even if a database marketer does not have postal costs, there are very sound reasons for taking the long view with customers. Maintaining a database and engaging in the customized marketing efforts associated with database marketing is expensive. Such expenses will generally only pay for themselves across time. If there is a great deal of churn among a marketer's customer base, the database marketer's analytical procedures may be wasted as the customer database at any given time may contain mostly newly acquired customers.

As a general rule, database marketing works best when the majority of people in the database desire a relationship with the marketer. Alternatively, if a significant number of customers are price-oriented customers, the marketer will likely lose them as soon as another firm offers a lower price. Therefore, engaging in database marketing efforts like loyalty programs when customers are price sensitive may likely not be a worthwhile effort.

THE ANALYTICAL PROCEDURES OF DATABASE MARKETING

There are a number of commonly used analytical procedures in database marketing. Although these procedures may differ on the specifics, in general, they are designed to uncover relationships among the various transaction variables in the database. Among other purposes, the analytical procedures can be used to segment customers into groups based on purchase patterns (e.g., frequently purchasing customers, the biggest spenders, and the most loyal customers); identify the customers that are most likely to respond to a specific offer; or identify the best prospects for a cross-selling effort. The analytical procedures of database marketing vary from fairly simple methods that have been around for a long time, such as recency–frequency–monetary (RFM) analysis, to very sophisticated methods that have recently emerged, such as neural network models.

RFM analysis. Years before database marketing was conceptualized in any sort of formal way, direct marketers (e.g., catalog companies) had observed that customers who had recently purchased from them, those who had frequently

purchased from them, and those who had spent a fair amount of money with them were the best prospects for new offers (Baier, Ruf, and Chakraborty, 2002). Over time, these informal observations grew into the use of the database marketing analytical procedure known as *RFM analysis*. RFM analysis involves the consideration of how recently customers have purchased from the marketer, measured in number of days, weeks, or months since last purchase (recency); how frequently customers have purchased from the marketer, measured as how many times they have purchased from the marketer (frequency); and the total amount of money they have spent with the marketer (monetary value). Generally, these three variables are used to predict which customers in a data file are the most likely to respond to a particular offer.

There are a variety of approaches used in RFM analysis, differing in terms of how the relative weights of the RFM variables are determined. One common approach to determining this weighting is known as *hard coding* (Drozdenko and Drake, 2002). Hard coding involves the development of a simple linear equation of the RFM variables, where weights for these three variables are assigned as a matter of judgment and past experience. For example, a marketer may reason from past experience with similar offers that recency should be assigned a weight of 2, frequency should be assigned a weight of 1, and monetary value should be weighted 0.5. Therefore, the linear equation provides a weighted score for each person in the data file; those with the higher scores should be the ones who are more likely to respond to a particular offer. The marketer can decide how far down in the data file it should go, for example, mail to 30% of the file, 50% of the file, and so on. Again, past experience would guide the marketer in this decision. Presumably, a greater profit would be realized from mailing to a smaller group of higher probability customers, based on RFM, than mailing to everyone in the data file. The relative weights of the RFM variables could also be determined empirically from the results of a similar mailing in the past. Regression analysis could be used to determine these weights.

An alternative approach to RFM analysis is a method advocated by Hughes (2005). One key

feature of Hughes' approach involves the use of a test mailing to a sample of customers in the data file prior to the selection of members of the data file who will receive the mailing. Hughes' approach begins with the sorting of the entire customer data file according to how recently the customers have purchased from the company. The customers are then divided into quintiles according to recency with these quintiles assigned a number from 5 to 1. Thus, 20% of the customers who most recently purchased are assigned a recency score of 5, the next quintile of customers are assigned a recency score of 4, and so on. Next, within each of the recency quintiles, the customers are sorted according to how frequently they have purchased from the marketer, placed in quintiles according to that variable, and given a score of 5 to 1. Finally, each of the frequency quintiles within the recency quintiles are sorted by total amount of money spent with the marketer, placed in monetary value quintiles, and assigned scores of 5 to 1. This procedure results in 125 unique cells with RFM scores of 555 (the most recent, most frequent within recency, and the most money spent within the other two variables) down to 111 (the least recent, the least frequent, and the least money spent).

Hughes suggests that a test mailing be sent to a sample of approximately 10% from each of the RFM cells. An analysis of the revenues and the costs of mailings will provide the response percent needed in order to break even. The response percent in the test mailing for each of the 125 RFM cells is compared to the break-even percent. The marketer then mails to the customers who were not in the test mailing, but only those from the RFM cells that broke even in the test. Typically, the number of cells that are mailed to is far less than the total of 125 cells; however, the profit is higher because of the mailing costs that are saved by not mailing to the unproductive cells.

Although more sophisticated analytical procedures have been developed in recent years, RFM analysis continues to be popular for a number of reasons. Ease of use and simplicity are often cited as reasons for its popularity, as well as the fact that it is a method that decision makers can easily understand (McCarty and Hastak, 2007). The simplicity of RFM is, however, often why

it is criticized as a database marketing technique. Critics point out that there are really no sound reasons for limiting the analysis to these three variables when there might be other transaction variables in the customer file that would help identify likely responders.

CHAID analysis. An analytical procedure that has been used by database marketers for segmentation and targeting purposes is chi-square automatic interaction detector (CHAID). Although this analytical procedure was developed for purposes unrelated to segmentation, it has proved to be very useful to database marketers.

CHAID is a classification method that can also be referred to as *tree analysis*. It is often used to find the most likely responders to target for a mailing or other marketing effort. For the purposes of this explanation, let us say that a direct marketer wants to do a major mailing and decides to conduct a test mailing of about 10% of its entire house data file of 1 000 000; the results of the test mailing will be used to identify those in the rest of the data file to receive the mailing. The response results creates the criterion variable to use for the CHAID analysis; this variable is

the dichotomous variable of those among the 10% who responded to a test mailing and those who did not respond. In this example, let us say that the overall response rate was 5% of those who were sent the test mailing (i.e., 5000 responders). A number of independent variables are then tested to see which of them are most useful in discriminating between responders and nonresponders. These independent variables can be any variables that the marketer might believe are related to response likelihood, such as the RFM variables, and other variables as well, such as method of payment (i.e., credit card or check), number of different items purchased from the marketer, and so on.

The CHAID procedure begins with a node of all the customers in the test mailing. CHAID searches among the identified independent variables for the one that best discriminates among the customers with respect to the criterion variable (i.e., respond or did not respond to the mailing). For the purposes of this illustration, let us say that the best discriminating independent variable is how frequently customers have purchased from the marketer. The procedure will split the original set of people who have

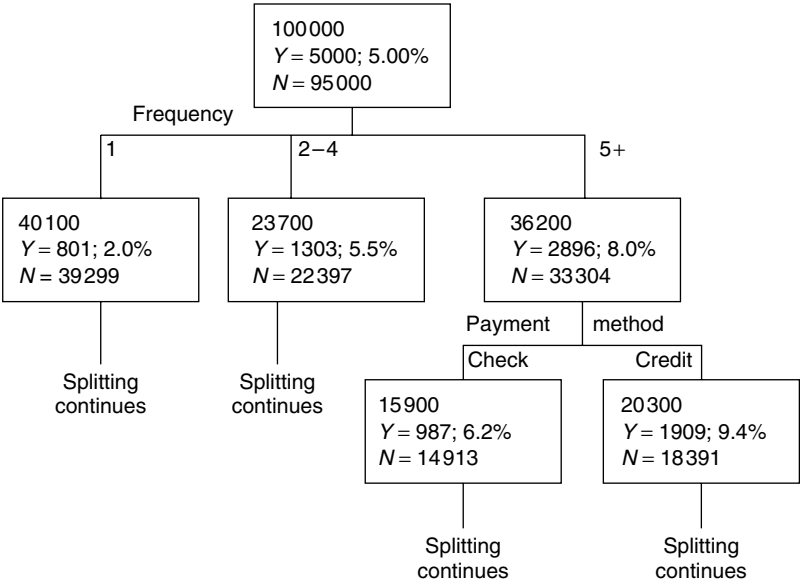

Figure 1 Example of a CHAID classification tree. This is the initial splitting of the CHAID analysis; splitting may continue until no significant differences are found.

sent the test mailing into two or more groups, depending on how this independent variable discriminates with respect to the criterion variable. For example, it may group those who have purchased five or more times together into one node, those who have purchased two to four times in a second node, and those who have purchased only once in a third node, as shown in Figure 1. Although the overall response rate was 5%, the response rate for these three nodes will be different on the criterion variable. Perhaps it is 8% for those who had purchased five or more times, 5.5% for those who had purchased two to four times, and 2% for those who had only purchased one time.

The CHAID procedure continues splitting the groups using this same logic. For each of these three nodes identified by the first independent variable (i.e., frequency), CHAID identifies the variable that best discriminates among the people in each of those groups. So, for example, among those who had purchased five or more times, the best discriminating variable might be whether they purchased with a credit card or check; the procedure will divide this group by the method of payment variable and the two resulting groups will have a different level on the criterion variable. The procedure may divide those who purchased two to four times on a different independent variable, as CHAID considers each of the groups from the original split independently in its search for the next best discriminating variable. This splitting of nodes continues until there are no more splits that would be statistically significant.

The CHAID procedure begins with a node of everyone who received the test mailing and ends with a number of nodes or groups of similar individuals with respect to the various independent variables. In this example, let us say that there are 30 final nodes. The nodes will differ with respect to their response rate. If the independent variables are indeed useful in discriminating between responders and nonresponders, then the response rate of the 30 different nodes may vary from percentages well above the response rate of the total group to some that are well below that of the total. The marketer can then place the rest of the total data file (i.e., the 90% who did not receive the test mailing) into groups

or nodes according to their values on the independent variables that defined the 30 nodes. At this point, the marketer can decide which of the nodes should be sent the mailing. This decision may be a function of how many people they can mail to given a certain budget or according to a break-even analysis. In other words, a response percentage that would be necessary to break even can be determined by the revenue and costs of mailing; the marketer can then mail to only those nodes that had that percentage in the test mailing.

CHAID is similar to Hughes' (2005) approach to RFM analysis in that it places customers into cells or nodes; however, CHAID determines these nodes as a function of how the independent variables behave empirically with respect to the criterion variable. Moreover, as noted, CHAID is not restricted the RFM variables as independent variables. CHAID has been shown to be superior to hard coding RFM (Levin and Zavari, 2001; Magidson, 1988); it has been shown to perform better than Hughes' approach to RFM when the overall response rate is low, but similar to RFM when the response rate is relatively high (McCarty and Hastak, 2007).

Multiple linear regression and logistic regression. Multiple linear regression (see MULTIPLE REGRESSION) is a general statistical procedure that is used to predict a continuous dependent variable from a set of independent variables. Multiple regression can be useful to database marketers in the instances when they are interested in understanding the relationship among a set of transaction variables in their data file and the criterion variable of interest is not a discrete variable (e.g., response/no response to a mailing).

An example of when multiple regression may be used is when a database marketer would like to know what predicts the dollar amount of business that customers will spend with them. For example, a casino may want to know what variables are related to higher spending among their customers. The reward cards given to customers provide estimates of this information. The criterion variable is amount of money gambled (often estimated for table games; accurately provided for slot machines if the customers insert their

card in the machines). There are a variety of independent variables that could be used as predictors including length of stay in the casino hotel, games that a customer plays (e.g., slot machines, table games), number of customer visits in a year, distance from customer's hometown to the casino, and demographic characteristics of a customer's hometown (available from Census Bureau data). The casino database marketer can use these independent variables to predict the criterion variable of money spent; the weights for the independent variables provide insights about the spending habits of its best customers. For example, the marketer may discover that the number of visits a customer makes is not as important as length of stay of visits in predicting spending level, or that bigger spenders play certain table games, and so on.

Another benefit from this sort of regression analysis is that it can provide information about customers who are good prospects for additional marketing. Customers who are predicted to be spending more than they actually are, given their levels on the important independent variables, can be sent promotional materials in an effort to increase their business with the casino.

Logistic regression (*see* LOGIT MODEL) is also utilized by database marketers. Logistic regression models a dichotomous dependent variable with a set of independent variables. Thus, it is useful for database marketing in instances when a marketer would like to predict response/no response to a marketing effort. A particularly useful aspect of logistic regression is that although the criterion variable is dichotomous (i.e., either a customer responded or did not); the resultant predicted values are probabilities ranging between 0 and 1. Thus, if logistic regression is performed on a test mailing or the results of a previous mailing, the analysis provides a weighted function of independent variables that best predict the response variable. The weights of the independent variables provide the information to develop the response probabilities for other customers (e.g., those who were not sent a test mailing). The marketer can decide what level of predicted response probability to use in deciding who should receive the mailing. A break-even analysis may tell the marketer that it will be profitable to mail to anyone in the data file who has a predicted

response probability of 30% or higher, for example.

Logistic regression is similar to RFM and CHAID in that it is typically used to determine who should receive a mailing or other marketing effort, based on information from a previous mailing or a test mailing. It differs from the RFM and CHAID in that it does not group people into cells or nodes, rather it provides an individual score (i.e., response probability) for each person.

Neural networks. Neural network analysis is one of the most recent advances in database marketing analytical techniques. These procedures have been widely used in a variety of data mining applications in business and nonbusiness areas (Berry and Linoff, 1997). Neural networks find patterns in data using an approach that mimics the human brain in how it makes connections. The procedure uses an iterative process to "learn" from training data sets; it develops a sense of these patterns and sharpens them during this learning process, analogous to how a human may learn and understand across time. Neural networks have advantages over many other analytical techniques used in database marketing in that they do not follow a specific empirical model (e.g., the linear model) and can be adapted to a wide variety of problems. A main disadvantage of neural networks is that the results of the analyses are not always easily understood (Berry and Linoff, 1997); therefore, they are not always easy to explain to decision makers.

PROSPECTING FOR NEW CUSTOMERS

Most database marketing activities are in support of marketing efforts directed toward a company's current customers. Companies do need to acquire new customers, however, in that there will always be some attrition of customers, no matter how good are a firm's relationship marketing practices. A key difference between the use of database marketing for current customers and the prospecting for new customers is that a firm does not have transaction information for customers that it is hoping to acquire.

In spite of this limitation, database marketing can help in new customer acquisition and there

are a variety of approaches to this. One approach is for a company to develop a demographic profile of their best customers and then acquire lists of people who fit this profile to “cold call.” The Census Bureau and commercial vendors (e.g., Nielsen Claritas) provide information about geographic areas that can help database marketers in their prospecting efforts. For example, if a resort hotel finds that its typical customers come from geographic areas with particular demographics and lifestyle characteristics, it can use such information to aggressively market in areas with similar demographic and lifestyle profiles. Therefore, the use of database marketing for prospecting is generally a matter of a firm understanding their own customers, then seeking others similar to their best customers.

SUMMARY

Database marketing involves the application of data mining techniques to the analysis of a company's customer transaction data in an effort to segment customers and to develop marketing strategies to customers. Database marketing is closely aligned with the concept of relationship marketing in that those who engage in database marketing generally need to consider their long-term relationships with customers for the cost of developing, maintaining, and mining a database to be profitable. Furthermore, since the information available in customer databases tends to allow marketers to provide personalized marketing strategies to their customers, such customized efforts tend to foster strong relationships with customers. A number of analytical techniques are utilized in database marketing to help marketers discover meaningful patterns in their customer data; some of these techniques

have been available for a long time (e.g., RFM analysis) while others have only recently been made available to the database marketing (e.g., neural network analysis). It is likely that the use of database marketing will grow as more types of organizations learn about its value in developing close relationships with customers.

the advertising budget

Douglas C. West

INTRODUCTION

The advertising budget is the financial statement and program put before top management for approval for spending on media, advertising production, and advertising services in order to meet advertising objectives. Expenditures on advertising can be enormous and often dwarf all other forms of marketing activity, and yet there is no evidence of widespread sophisticated practice (Kissan and Richardson, 2002). Many of the methods employed are historic and intuitive and have not been taught so much as observed and classified by researchers. To a great extent a muddled business reality has been formalized and compartmentalized by researchers.

METHODS

The leading approaches and specific methods, with their percentage use as indicated by surveys are listed below (see Synodinos, Keown, and Jacobs 1989; Prendergast, West, and Shi 2006; Farris and West, 2007; Belch and Belch, 2009, pp. 226–42):

Judgmental methods (ca 25–30% of budgets):

- **Arbitrary:** The advertising budget is solely determined on the basis of what is “felt” to be necessary.
- **Affordable:** The organization determines what it can spend on areas such as production and operations and then decides how much it can then afford for advertising.

Objective and task (ca 25–30% of budgets):

- Spending is in accordance with what is required to meet the advertising objective(s) which are ranked by importance. Tasks are agreed upon to meet these objectives and then costs estimated. If the campaign cannot be afforded, objective(s) that are of lower importance are eliminated until the budget can be afforded.

Measurement (ca 20% of budgets):

- **ROI:** Advertising is considered an investment, and money is spent to the point where the ROI is diminishing.
- **Incremental:** The budget is allocated in a series of tests (e.g. spend 5% more or 5% less) mainly using direct and interactive media such as direct mail, the Internet, and tools like barcode data. Spending is increased or decreased in line with the results achieved.
- **Quantitative models:** Computer simulation models involving statistical techniques such as multiple regression analysis are used.

Percentage of sales (ca 15% of budgets):

- **Percentage of last year’s sales:** Set as a percentage of previous financial year’s sales.
- **Percentage of anticipated sales:** Set as a percentage of the firm’s anticipated sales.
- **Unit sales:** The organization allocates a fixed percentage of unit price for advertising and then multiplies this amount by projected sales volume (e.g. 5% unit price \times 200,000 units forecast).

Competitive (ca 5–7% of budgets):

- **Competitive absolute:** The budget is set in line with that of the closest rival.
- **Competitive relative:** All the competitors in the market tend to spend in line with their market share.

CHOICES

From an academic perspective, advertising budgeting studies can be largely compartmentalized as either “method” or “organizational” in their focus. Method studies have examined the effects of size, market type, performance, and country on advertising budgeting, but no definitive conclusions have arisen. Studies have given a broad measure of support for the increasing use of more complex methods namely, the “objective and task,” and to a lesser extent, measurement methods, from the 1980s onward. There are some signs that Business-to-Consumer (B2C) advertisers, larger

2 the advertising budget

companies, better performers, and those within more highly developed economies are more likely to use measurement methods, but the evidence is not strong. Organizational studies have examined the political processes and structures that affect setting any budget.

When it comes to managers, the advertising budgeting decision is part of their overall decision-making and *satisficing*, which involves seeking alternatives and choosing the first one that exceeds your expectations, is a common approach. Managers are often constrained by a multitude of factors, but particularly by lack of time, data, and resources and the politics of their own organization. They know how to set their advertising budget ideally, but yet have to compromise in order to develop the budget in practice. So while they might preferably want to do some sophisticated econometric modeling, instead they stick to the well tried and trust percentage of sales method for example, because it produces a budget good enough to fit their needs and saves a lot of time.

SUMMARY

The advertising budget is an important decision. Spend too much and resources will be wasted. Spend too little and opportunities will be lost. The main methods are judgmental, objective and task, measurement, percentage of sales, and competitive and they can be used singularly or in combination. Academics have largely investigated the effect of market and firm variables on choices and issues related to organizational structure and politics. Managers

often make their choices of budgetary method based upon *satisficing*. Faced with scarcities of all kinds (information and time in particular), managers regularly compromise the ideal for what is practical.

consumer rebates: current issues and research

Tim Silk

OVERVIEW

Consumer rebates have become a popular price discrimination and promotional tool among retailers and manufacturers to increase sales on a wide variety of durable and consumer goods. The promotion industry estimates that over 400 million rebate checks are distributed annually in the United States totaling \$6 billion (Spethman, 2006). Rebates are typically offered in one of two formats. Instant rebates are less common and mirror traditional price discounts by offering a discount at the point of sale. Delayed payment rebates (e.g., mail-in rebates) are more common and require consumers to exert effort after purchase to receive a discount. The effort required can vary but typically involves mailing an application form, sales receipt, and proof of purchase by an expiry date that can range from 15 to 90 days after purchase. On-line rebate redemption is becoming more popular and similarly requires consumers to verify purchase information to protect firms against fraudulent applications. Rebates are distinct from coupons and other forms of price promotion because the effort required to receive the discount occurs after rather than before purchase. This difference has important implications for consumer behavior and rebate redemption rates.

BENEFITS TO FIRMS AND CONSUMERS

Rebates can be effective at increasing sales by encouraging trial, brand switching, and repeat purchase (Promotion Marketing Association, 2005; Tat, Cunningham, and Babakus, 1988). Rebates are attractive to firms because the price discount is paid after purchase, which offers two key benefits. First, rebates have a more favorable impact on key performance metrics such as revenues and comparable store sales vis-à-vis coupons and discounts which are subtracted from the purchase price at the time of sale. Second, firms can benefit from “slippage” which occurs when consumers are attracted by the rebate to make a purchase but later fail to

redeem the rebate. Rebates are attractive to consumers because they offer discounts that are typically larger than those of other types of price promotions. Low redemption rates conceivably allow firms to offer larger discounts than would be possible if the discount were realized by all consumers (Chen, Moorthy, and Zhang, 2005). Thus, rebates are essentially a mechanism used to distribute discounts to consumers who perform the effort required to achieve the discount.

CONTROVERSIES AND RESEARCH FINDINGS

It has been well documented that consumers often fail to redeem rebates, resulting in low redemption rates (Jolson, Weiner, and Rosecky, 1987; Silk, 2004; Soman, 1998). Slippage and the question of why some consumers fail to redeem rebates has become a controversial issue that has attracted the attention of law makers and researchers. While no federal regulation exists for rebates, state legislators have become proactive in introducing nearly 50 bills on rebates (Silk and Pechmann, 2009). Some bills have been enacted into law, resulting in a patchwork of state regulations that complicate national promotions. Research has examined rebate characteristics and consumer behavior that contributes to slippage. This research has shown that foregoing a rebate can be a rational choice that does not disadvantage consumers. For example, Chen, Moorthy, and Zhang, (2005) show that rebates are similar to option contracts where consumers decide after purchase whether or not to exercise their option to redeem, in effect customizing price according to each consumer’s marginal cost of time and utility of income. Consumers may also forgo the rebate if it has no bearing on their purchase decision, which is supported by data showing that redemption rates are significantly higher when calculated as a percentage of incremental sales (i.e., consumers influenced by the rebate) rather than total sales (Promotional Marketing Association, 2005). Research also suggests that biases in judgment and decision making also contribute to slippage. Soman (1998) finds that consumers tend to underestimate the cost of future effort relative to apparent savings. As a result, purchase decisions are more sensitive to the rebate amount than to the

2 consumer rebates: current issues and research

required effort, whereas redemption behavior is more sensitive to effort than to the rebate amount. Consumers are also highly influenced by redemption deadlines (Silk, 2008). Longer deadlines make consumers more confident that they will redeem, which encourages purchase. Paradoxically, longer deadlines also foster procrastination, which results in lower redemption rates. Consumers are most likely to redeem when deadlines are shortest because short deadlines mitigate procrastination and forgetting. Many manufacturers and retailers have moved toward consumer-friendly rebates in an effort to simplify the redemption process and encourage repeat patronage.

advertising message appeals

Marla B. Royne

An advertising message appeal is the connection between the emotion or logic of the advertisement and the consumer's response to the ad (Wells, Moriarty, and Burnett, 2006). For an advertisement to be effective, the most appropriate appeal must be selected and executed in a creative manner. In general, message appeals can be categorized into two overarching categories: emotional and rational.

Emotional appeals are directed primarily at an individual's psychological, social, or symbolic needs (Arens, Weigold, and Arens, 2008). They are grounded in one's feelings and are generally designed to increase the overall liking for a product, although both negative and positive emotional appeals can be used. The basic objective of an emotional appeal is for consumers to make decisions based on their feelings, as opposed to utilizing logical, rational decision-making approaches. Emotional appeals touch on a variety of feelings including fear, humor, love, anxiety, and sex. To potentially enhance their persuasive effects, an advertisement can actually include more than one type of emotional appeal. Since they are designed to persuade by manipulating one's feelings, emotional appeals often come under scrutiny.

Rational appeals are generally directed at an individual's practical and functional need for a particular product (Arens, Weigold, and Arens, 2008). They are grounded in traditional models of information processing where consumers are expected to make purchase decisions based on an individual's sense of logic and reasoning. The purpose of a rational appeal is to emphasize the characteristics, features, and benefits of the product to demonstrate the value of owning or using that particular brand. Such appeals may include detailed information about a product such as specific features, durability, and value. Successful rational appeals rely on their persuasive power of arguments or reasoning. Examples of rational appeals include price, quality, performance, reason why, and comparative advertising.

For years, effectiveness of the appeal has been believed to be based on the corresponding category of product (Stafford and Day, 1995),

whereby there is an appeal by product interaction (e.g., Golden and Johnson, 1983; Aaker, Batra, and Myers, 1992), and that the type of appeal should match that of the product (Holbrook and O'Shaughnessy, 1984; Johar and Sirgy, 1991). More recent research suggests that the choice of message appeal is not that simple. In fact, one perspective is that the most successful advertising integrates functional benefits with emotional values.

Regardless of the type of appeal selected, advertisers must carefully choose the most appropriate one for the particular product being advertised. This means that the characteristics and nature of the product must be considered to ensure that the tone of the advertisement accurately reflects the intended purpose and usage of the featured product.

regulating advertising in the United States

Jef I. Richards

THE IMPLICATIONS OF COMMUNICATION-AS-PRODUCT

Like any industry, the industry that creates and delivers advertising is subject to a long list of regulations, including those involving employment, zoning, securities, taxation, and more. But the regulations unique to this industry deal largely with its products: the advertisements and related promotional devices. Other industries, of course, also must deal with regulations on their products. The food industry, for example, must meet requirements concerning the quality of ingredients in a product, the amount of time it can remain on a store shelf, and so on. But the advertising industry differs from most others, in that its products are messages, that is, communication.

The First Amendment of the United States (US) Constitution guarantees freedom of communication (i.e., “speech”). It does not, however, promise freedom without some concomitant responsibility. This means there are some limitations imposed on communication, in spite of the amendment’s facial assurance of “no law . . . abridging the freedom of speech.” For instance, there are “reasonable time, place, and manner” restrictions applicable to virtually any form of communication, including advertising (Langworthy, 1983).

In addition, historically, some different types of speech receive different degrees of protection. Political speech is seen as the principle or “core” purpose behind the first amendment, so it has received more protection than other forms of speech (Richards, 1996). Advertising falls into a category called “*commercial speech*,” that has traditionally received far less protection than political speech.

Although the first amendment became law in 1791, it was more than 150 years before an advertising case reached the Supreme Court. And when it did, in *Valentine vs. Chrestensen* (1942), the Court clearly stated that commercial advertising was not constitutionally protected. Indeed, commercial speech was not considered a form of speech protected by the

first amendment until *Virginia State Board of Pharmacy vs. Virginia Citizens Consumer Council* (1976). Even after that, the precise extent of that protection continued to be subject to significant debate, even within the Supreme Court (Richards, 1997).

The latest, and in some respects the clearest, statement regarding the status of commercial speech is found in *44 Liquormart vs. Rhode Island* (1996). There, the Court stated that more regulation of commercial speech, as opposed to other speech, is permitted *only* to assure fair bargaining in the marketplace. It suggested that restrictions on commercial speech unrelated to fair bargaining would be subject to standards more like those applied to other protected forms of speech. That decision seemingly elevated the constitutional protections afforded to advertising, and all forms of commercial speech.

As a consequence, not every desired or attempted regulation of advertising will pass constitutional muster. Even prior to *44 Liquormart*, attempts to ban or severely restrict certain types of advertising, like that for cigarettes or alcohol, frequently were thwarted by the first amendment. For those laws, the government must prove that a legitimate purpose will be served in some significant way, and that the law is narrowly tailored to serving that purpose (Central Hudson, 1980).

On the other hand, regulations dealing directly with fair bargaining issues, such as advertising deception, generally found no obstacle in the Constitution (*44 Liquormart*, 1996). Advertising that misleads threatens not only the individual consumer but also the assumptions on which the free market system is founded, so the courts recognize a need to curtail deceptiveness.

DECEPTIVE ADVERTISING BASICS

The principle US government agency charged with regulating deceptive advertising is the Federal Trade Commission (FTC). The basis of its authority is the FTC Act (1914), which states, “Unfair methods of competition in or affecting commerce, and unfair or deceptive acts or practices in or affecting commerce, are hereby declared unlawful.” By that simple statement, the FTC is granted power over both deceptive

2 regulating advertising in the United States

and “unfair” acts or practices, which actually encompasses more than deception and reaches marketing practices beyond just advertising. Deceptive advertising, however, is a significant part of the FTC’s responsibility (Richards, 1990).

The fundamental principle of deception is that the consumer understands the advertisement to claim something about a product or service that is untrue. The consumer’s understanding is key. If the meaning conveyed to the consumer’s mind by an advertisement differs from the reality of the product attribute, the advertisement is considered deceptive (Preston and Richards, 1986).

Advertisers might argue they had no intent to deceive, but since consumers can be deceived even under the best of intentions, the FTC considers advertiser intent essentially irrelevant. And because it is the conveyed meaning that is critical, the actual wording in the advertisement can even be true yet still deceive. This means disclaimers in small print will not exempt an advertiser from FTC action, if the consumer is unlikely to read or understand the disclaimers. Again, the consumer’s understanding is the governing criterion.

The FTC considers an advertisement deceptive if it meets three requirements:

1. There is a representation, omission, or practice.
2. It is likely to mislead consumers acting reasonably under the circumstances.
3. It is material.

The first of these makes it clear that not only a representation but also an omission of information can result in legal action. Failure to disclose something can be as deceptive as an outright lie. The second, by including the word “likely,” reflects the FTC standard that a claim can be regulated without it having deceived anyone, so long as deception is probable. Also, in this second part, the FTC makes it clear that only consumers who act reasonably will receive protection, and that the agency will not go out of its way to protect those holding unreasonable beliefs (Cliffdale Associates, 1984).

The third requirement concerns the claim’s “materiality,” or importance. A claim (or

omission) must not only have the probability of deceiving consumers but it must also be nontrivial. A claim is material to consumers if it is “likely to affect their choice of, or conduct regarding” a product or service (Cliffdale Associates, 1984).

This definition sets the parameters of proof for any advertisement to be declared deceptive.

Evidence. If the FTC receives a significant number of complaints about any advertisement, the agency’s staff then collects evidence to evaluate whether it might be deceptive. If the evidence supports a charge against the advertiser, the staff takes that evidence to the commissioners and recommends that a formal complaint be sent to the advertiser. A complaint is the initiation of legal action.

The FTC tends to assume that any claim made by an advertiser is material. This means the only evidence needed to find deceptiveness is to discover (i) what claim is conveyed to consumers’ minds and (ii) whether that conveyed claim is accurate.

Commissioners look to a variety of evidence types in determining what claim is being conveyed (Thompson Medical Co., 1984). The most common is to look at the advertisement itself. Where a claim is explicit, no further evidence of the conveyed message may be needed. On the other hand, where it is an implied claim the commission may look to a broad range of evidence, including expert testimony and consumer surveys.

Proof of a claim’s accuracy is called “*substantiation*.” For advertisers, the most important aspect of the FTC approach to substantiation is that an advertising claim must not be made without—at a minimum—a *reasonable basis* for believing the claim is accurate. There was a time when advertisers could make a claim and not worry about its accuracy unless and until the FTC challenged the veracity of the claim. But, today the advertiser must have in hand some reasonable evidence of the claim’s truth at the time the claim is included in an advertisement. What evidence constitutes a reasonable basis for believing a claim to be true will vary greatly from situation to situation, depending on the product, the type of claim, what experts believe

is reasonable, as well as other factors (Thompson Medical Co., 1984).

The legal burden of proof is on the advertiser. In practical terms, this means when advertisers are charged with making deceptive claims, they are guilty until proven innocent.

The FTC, besides judging whether an advertising claim is deceptive, also plays other roles in advertising regulation.

OTHER RESPONSIBILITIES OF THE FEDERAL TRADE COMMISSION

Deceptiveness is not the only way advertising can potentially harm the public. Neither is it the only concern of the FTC. The law empowering the agency gave it authority over both deceptive and “unfair” practices (FTC Act, 1914). This allows the commission occasionally to reach advertising and marketing methods that do not deceive yet might be otherwise harmful. Unfairness is carefully defined in the FTC Act, but it remains sufficiently broad so as to reach a variety of marketing practices by applying a cost-benefit analysis to assess whether the public risks outweigh the benefits of the particular practice (Calkins, 2000).

Historically, the unfairness power has been used sparingly, but it has proved especially useful in reaching practices that threaten particularly vulnerable populations like children and the elderly, where a marketing tactic might not be deceptive and yet takes advantage of a group’s susceptibility. More recently, it has been applied to problems arising from new technologies, such as “pagejacking” on the Internet (Calkins, 2000).

This agency also has responsibility for issuing guidelines and regulations. The former are not law, but provide marketers with guidance on how to comply with the law. By contrast, regulations are law. They identify specific practices that already have been determined deceptive or unfair, or to violate some other law enforced by the FTC, and noncompliance with a regulation can result in a fine or other penalty.

FTC REMEDIES

Penalties can result for violation of regulations, as well as for violations of FTC orders. However, the term “*penalty*” connotes punishment, which

is beyond the FTC’s power. Instead, its authority is limited to “remedies,” orders designed to force a marketer to repair a situation rather than to punish the marketer.

For example, once a marketer is found responsible for using a deceptive claim, the commission has only a few options, none of which constitute punishment. A “cease and desist order” is the most common remedy. This simply orders the marketer to stop using that claim. If the deceptiveness stems from important information being absent from the advertisement, another possible remedy is “affirmative disclosure,” which commands the advertiser to include certain information in future advertisements. And the most rare remedy is “corrective advertising,” which is reserved for only those situations where there is a long history of using a deceptive claim. In those situations, the FTC can require a more explicit corrective disclosure (Wilkie, McNeill, and Mazis, 1984).

It should be noted, however, that the FTC most often does not even reach the point of ordering any of those remedies. Most cases end long before the advertisement is officially found deceptive, because advertisers merely acquiesce to FTC demands to terminate or modify the offending claim before any hearing is held. This results in a “consent decree,” whereby, the advertiser voluntarily consents to make changes.

And then there are other particularly egregious cases where the FTC’s available remedies are just inadequate to fix the problem. While it has no authority to punish marketers, in these situations, the commission can turn the case over to a court, and courts have far more options available to them, including the ability to order the marketer to pay back consumers for their losses (Ward, 1992). These “section 13(b)” cases have become a popular solution for the regulators.

Although the FTC is the primary federal force to stem the excesses of advertising, it is not, by any means, the only form of advertising regulation. Indeed, the FTC Act is not the only law that imposes limits on the advertising industry.

OTHER SOURCES OF REGULATION

There are scores of laws that affect advertising. Many of them are industry-specific. As just two examples, there are laws restricting

4 regulating advertising in the United States

certain claims used in advertising agricultural plant materials, and there also are laws regarding advertising of textile fiber products. There also are laws that cut across multiple industries, like the laws aimed at protecting consumer privacy, which clearly affect advertising.

At the same time, there are federal administrative agencies other than the FTC engaged in advertisement regulation. The two most actively involved are the Federal Communications Commission (FCC), because it regulates media over which so many advertisements are conveyed, and the Food and Drug Administration (FDA), which oversees so many of the products being advertised. Other agencies, like the Securities Exchange Commission or the Department of Transportation, likewise may play a role on the more rare occasions where their area of responsibility is involved.

And then there are state and local governments that frequently do play a role in advertising regulation (Richards, 1991). States have laws, including what are sometimes called “*Little FTC Acts*,” to regulate advertising within their borders.

CONCLUSION

The legal environment of advertising in the United States is complex, because the range of products, services, advertising concepts, and claims in advertising is virtually limitless. Moreover, as with any body of law, it is constantly changing. Consequently, any specific advertisement or claim might invoke legal principles not even mentioned above.

direct-to-consumer (DTC) advertising

Marla B. Royne

Direct-to-consumer (DTC) advertising is the advertising of pharmaceutical drugs and other prescription products directly to the consumer. While the first modern DTC ad appeared in 1981 (Friedman and Gould, 2007), a voluntary moratorium on such advertising followed (Woloshin *et al.*, 2001). In 1985, the moratorium was lifted, but the information requirements were so strict that advertisers often found DTC advertising to be cost prohibitive. In 1997, the Food and Drug Administration (FDA) relaxed the existing regulations, paving the way for massive national advertising campaigns for prescription drugs (Auton, 2004); today, DTC advertising permeates the mass media. In 2008, the pharmaceutical industry spent \$4.3 billion on advertising spending (en-us.nielsen.com, 2009). Despite this massive budget, it actually represents a decrease of 18.4% from the previous year (en-us.nielsen.com, 2009). Moreover, Americans see as many as 16 hours of prescription drug advertising each year (Brownfield *et al.*, 2004).

DTC advertising has been a particularly controversial topic since the modified legislation in 1997 that generated large-scale television and print advertising campaigns for prescription drugs (Auton, 2004). And while the Pharmaceutical Research and Manufacturers of America (PhRMA) subsequently issued voluntary guidelines on DTC advertising, questions abound on whether regulations adequately protect consumers from such overt marketing communications.

The United States and New Zealand are currently the only countries that actually allow DTC advertising, although countries in Europe have seen increased pressure to permit the practice. At the same time, New Zealand's health officials have been lobbying for a ban on DTC advertising for several years (Advertising Age, 2005). The controversy stems from the debate on whether DTC advertising *informs* or *influences* customers. Individuals supporting DTC advertising argue that media messages provide the information needed for consumers to assist their doctors in making an informed choice in their own care (Auton, 2004; Meek, 2001). Those

individuals against the practice feel that DTC advertising is not informative and exists solely to persuade customers to ask their doctors for an advertised prescription. Critics further argue that marketing tactics serve only to increase the demand for more expensive medications (Peyrot *et al.*, 1998).

In addition, DTC advertising critics believe DTC advertising medicalizes normal everyday experiences and treats these experiences as a disorder (Mintzes, 2002). Another concern is that ads sometimes leave the impression that the newer advertised drugs are superior to existing older drugs, when in fact this is often not the case. Critics also suggest that advertisers fail to include "balanced" information in their ads, one of the guidelines recommended by the 2005 PhRMA voluntary guidelines (Welcher, 2005). Interestingly, an increasing number of consumers do not feel that such advertising helps them make better health decisions nor do they feel that it provides enough information on the risks or potential negative effects of the drug being advertised (Friedman and Gould, 2007).

While several DTC advertisements have been pulled due to misleading information, others have been lauded for providing the information needed in a positive, upbeat manner (e.g., Dick-Rath, 2009). This campaign for Gardisal, a vaccine developed to prevent human papillomavirus (HPV), had positive outcomes for both the consumer and the company (Dick-Rath, 2009). This type of campaign demonstrates that DTC advertising may, indeed, have an important place in the consumers' decision-making process when it comes to their health.

Despite the vast concerns about DTC advertising, it is unlikely that the United States will ever see a complete ban on the practice. However, with PhRMA's voluntary guidelines and the FDA's oversight, changes to DTC advertising may be on the horizon. Such changes should result in positive outcomes for consumers, first, and pharmaceutical companies, second.

product placement

Cristel Antonia Russell

Product placement refers to promotional practices that integrate brand communications within the content of entertainment products. Brand communications are now present in the content of a broad range of entertainment vehicles, including TV and movies (Wasko, Phillips, and Purdie, 1993), radio shows, songs and music videos, video games, plays, and even novels (Friedman, 1985). The increased mingling of advertising with the entertainment world has generated a slue of newly coined terms to reflect these trends, such as hybrid advertisement (Balasubramanian, 1994) or the “Madison and Vine” expression, reflecting the physical intersection of the advertising industry’s New York City hub, on Madison Avenue, and the entertainment hub on Vine Street (Donaton, 2004).

Many factors contribute to advertisers’ increased interest in and use of product placement. It has grown mainly in reaction to the increasing advertising clutter, escalating advertising costs, and the reduced effectiveness of traditional advertising messages. Consumers are exponentially exposed to commercial messages but at the same time they are finding new ways to avoid them. An In-Stat/MDR survey found that 54.3% of consumers claim to skip 75–100% of commercials (Jaffe, 2005). In 2004, a Knowledge Networks study concluded that 47% of viewers switch channels while watching TV (Jaffe, 2005). These statistics do not account for the impact of new technological advances which are giving consumers more control over how they consume entertainment, and making it increasingly easy for them to avoid commercial messages. With the introduction of personal video recorders (PVRs), also referred to as digital video recorders (DVRs), such as TiVo or replay TV, consumers can not only more easily fast-forward through commercials but they can now also easily skip them altogether with a PVR’s auto-skip function. A Forrester Research’s study of PVR usage by 588 users in the United States found that 60% of their time, on average, was spent watching programs that were prerecorded or delayed, which in turn

resulted in 92% of commercials being skipped. Thirty percent of respondents said they watched no commercials at all (Zutter, 2005).

Product placement epitomizes the blurring of the lines between advertising and entertainment. In audiovisual media, placements can be categorized based on their modality of presentation, visual or audio. The visual appearance of brands is justified by the need to create realistic settings for movie or TV sets. According to records available on www.brandchannel.com, an average of 18 brands was visually placed in the roughly two hundred top movies released between 2001 and 2005. During the 2004–2005 TV season, more than 100 000 product placements appeared on the six broadcast networks, an increase of 28% from the previous season, according to Nielsen Media Research (Manly, 2006). According to Nielsen Product Placement research, the most common form of product placement in 2005 was a simple spot in the background of a show or the brand used as visual prop in the program (Edwards, 2006a). Visual placements are common in video games, where they usually take the form of hoardings, billboards, and traditional signage placed throughout a game, for example, on the sides of buildings in a motor sport game, which essentially mimic real-life advertising spaces (Murphy, 2006). Audio mentions tend to have more impact because they imply an endorsement by the celebrity. For instance, the popularity and reputation of many talk show hosts can make a simple mention of a product on a talk show extremely successful.

A HISTORICAL PERSPECTIVE

Although product placement is gaining in popularity, it is not new, and there is a long history of such intermingling between content and advertising. Marketers’ approach to using entertainment content to promote their products dates back to the use of branded products in motion pictures (Newell, Salmon, and Chang, 2006). This practice was variously termed *publicity by motion picture* (Dench, 1916), *co-operative advertising* (Harrower, 1932), *tie-in advertising* Tie-in Advertising (1951) and *trade outs* (Lees and Berkowitz, 1978), or even *exploitation* (Steele, 1925). It represented a

2 product placement

cooperative venture between a media maker and a manufacturer, in which on-screen exposure of a product, off-screen endorsement by an actor, or a combination of those were traded for paid advertising and unpaid promotions by the manufacturer (Eckert, 1978). The use of tie-ins became standardized in the 1930s. The Walter E. Kline Agency in Beverly Hills provided studio executives with multiple-page lists of products available for on-screen use in motion pictures, including Remington typewriters, IBM tabulating machines, Singer sewing machines, and General Electric appliances (Newell, Salmon, and Chang, 2006). Products were offered rent free in return for publicity stills for use in manufacturers' advertising (Kline, 1931).

These tie-in promotions benefited multiple players in the filmmaking and distribution industry. For the motion picture producer, they delivered free props. For the manufacturer, they provided in-theater exposure for products to a captive audience and the chance for the product to be associated with well-known actors on- and off-screen. In addition, they provided the marketing option to use footage or publicity stills from the movie in the company's outside advertising. For the motion picture distributor, this "as seen in the motion picture..." early form of cross-promotion provided zero-cost advertising for the motion picture. Many of the same benefits apply today.

The practice eventually evolved into sponsor-owned programs, where manufacturers had full control over how their products were portrayed (see SPONSORSHIP AND EVENT MARKETING). Starting in the 1930s, consumer product manufacturers invested in the production of radio programs to reach their target audiences (Lavin, 1995). This phenomenon was particularly visible in the "soap opera" genre, a term that actually testifies to the blending of advertising of actual soap products and programming. Similarly, radio programs were developed directly by detergent companies, notably Procter & Gamble, to promote their brands by integrating them into the scripts. When soaps emerged on TV in the 1950s, the close connection between programming and advertising continued and marketers maintained direct control over the

shows' storylines and creative design (Barnouw, 1975). Advertising agencies produced shows like "The Colgate Comedy Hour" and "Texaco Star Theater," in which a chorus line of dapper gas-station attendants opened each show by singing the Texaco jingle ("Oh, we're the men of Texaco, we work from Maine to Mexico") before introducing the host, Milton Berle (Manly, 2005).

The practice of show sponsorship began to decline as advertisers realized they could better reach their target markets by spreading their advertising budgets across many shows rather than by spending it all on one (Savan, 1996). Since the mid-1980s, however, the trend has reversed and advertisers are now again trying to tie their brands to entertainment vehicles. One factor that fostered the unprecedented proliferation of product placements and campaigns tied to movies occurred during the 1980s and early 1990s (Wasko, Phillips, and Purdie, 1993) was the use of Reese's Pieces to attract the alien in the 1982 hit movie *E.T.* The success of the movie and the placement led to an increase in awareness of the brand as well as sales increases of 65% (Winsky, 1982).

HOW THE PRODUCT PLACEMENT WORLD WORKS

A direct consequence of the increased popularity of product placement is the boom of a specialized industry (Wenner, 2004). Product placement is practiced by more than 100 companies internationally (Nelson, 2004). The institutionalization of the industry is evidenced by such professional trade associations as the Entertainment Marketing Association (EMA) whose association members include placement agents, studio representatives, and marketers. A review of EMA membership reveals that in North America, product placement firms are mainly located in the Los Angeles area, hub of the entertainment world, and in major advertising centers such as New York, Chicago, and Toronto Entertainment Marketing Association (2007). The three main types of players are the production side, the agency side, and the client side.

The production side. These are the producers of entertainment content, such as TV and movie

studios, music production companies, or video game makers. In the audiovisual arena, the bases for identification of potential for inclusion of product placements are scripts. Studios send scripts to clients whose permissions are legally required to use these brands in their scenes, either directly or through the intermediary of product placement agencies. Movies generally include between 100–150 brands that need such permissions (Russell and Belch, 2005). Decisions on whether to include a branded product and choices of which brand to include are sometimes made by the directors, producers, or actors. Their criteria for selection are generally driven by artistic needs or the desire to make the story realistic.

Increasingly, an objective for using product placements is financial. This may come in various forms. Federal Communications Commission (FCC) rules prohibit payment for placements on TV shows but not in other media, such as movies. However, even on TV, the regulations do not prevent other forms of agreements between producers and advertisers. A common form involves the provision of the product as payment, similar to trade deals made in the media industry, that is, providing products and services in return for having the product shown at no direct cost. This form of payment reduces production and overhead costs.

A major limitation of simply sending products out to a placement agent or directly to the producers is that it provides limited to no control over how the brand is ultimately portrayed. Of course, producers must take into account existing contracts with advertisers to avoid conflict of interests but this is always clear-cut. Another concern on the production side is the potential violation of creative and artistic freedom associated with increased commercial content (Manly, 2005). Producers sometimes turn down placement deals (Manly, 2005). Some creators of television shows worry that the commercial impulse could turn storytellers into shills and keep more provocative fare off the big networks.

The client side. The companies that use product placements to promote their products and/or brands range from small to large Fortune 100 corporations. Clients sometimes review scripts provided by their agents or directly by the

production companies. Their perspectives often differ from agents' because they have to consider the placement as part of their overall brand strategy. However, given the relative novelty of the practice, it is not always clear who in the client organization has responsibility for it. In fact, organizations that do not think of product placement as a fully integrated component of their strategic marketing activities, but rather as an accessory tool, often delegate such responsibilities primarily to their agents.

The agency side. Analogous to advertising agencies, placement agencies serve as the intermediary between the production side and the client side. These agencies are paid a fee for their services and essentially become agents for the producers (Bohn, 1986). The primary basis for the agency participation in this industry is to receive direct monetary compensation. Many of today's placement agents started as prop masters on the studio side and realized the opportunity for an intermediary to streamline and improve the communication channels between the two sides, and hence the many agency start-ups in the 1980s.

Some companies now coordinate their product placements in-house but many use an intermediary agency that has closer links to the entertainment world. In many instances, agencies are provided with advance copies of these scripts which are reviewed for placement opportunities, matching existing clients to these opportunities, and/or seeking new participants. Because placement agents are not trained as brand managers, their criteria for deciding whether one of their clients' brands is appropriate for a particular medium is often more opportunistic than strategic.

The product placement industry is evolving from a simple means for studios to cut costs, and marketers to expose their products to a more sophisticated industry in which product placement agencies are increasingly assuming the role of traditional advertising agencies. At the same time, traditional advertising and media agencies are beginning to incorporate product placement in their services. Major holding companies are increasingly adding entertainment consultants and public relations powerhouses to their portfolios.

ROLE OF PRODUCT PLACEMENT IN
INTEGRATED MARKETING
COMMUNICATIONS (IMC) MIX (*see*
INTEGRATED MARKETING
COMMUNICATION STRATEGY)

Placement efforts can have a strategic role in a fully integrated promotional campaign. There is no question that developing objectives and evaluating the effectiveness of placements is easier when they are associated with other, more familiar components of the integrated marketing communications (IMC) mix. Whenever a placement is used to initiate a theme for a more traditional advertising campaign, advertising objectives and effectiveness measurement tools can be used. Since cross promotions are becoming more common to enhance product placements and integrations in movies, efforts can be assessed with sales promotions methods. Placements can also serve as the backbone of a public relations campaign, to generate word of mouth or press coverage. For instance, in what was named a "Top 5 Marketing Events in 2004," Oprah gave away 276 Pontiac G6 cars to car-deprived audience members (Grillo, 2005). The stunt cost GM at least \$7 million but resulted in more than 600 TV news stories, and the words "Oprah" and "Pontiac G6" rose to the ranks of Yahoo! and Google's top 10 most requested search terms (Grillo, 2005). In the end, the placement-based PR campaigns resulted in Pontiac selling more than 16000 G6 models in 2004 (Grillo, 2005). Finally, the increasing opportunities with interactive television and Internet-based campaigns allow the use of direct marketing tools to evaluate the impact of placements, especially when a direct response component is built into the campaign.

MEASURING IMPACT (*see* MARKETING
METRICS; ADVERTISING EFFECTIVENESS)

One of the main difficulties related to product placement lies in measuring impact. Key indicators such as audience reach and frequency are often next to impossible to obtain (Murphy, 2006). Some argue that the minimal cost of stand-alone placements does not necessarily warrant much attention be paid to the returns (Schiering, 2003). As the industry matures

and opportunities for large scale placements and integrations grow, valuation systems will be needed. However, so far, there is little sophistication in this realm and value-like effectiveness-assessment is essentially still very much subjective and anecdotal evidence prevails, mainly with a biased focus on success stories (Russell and Belch, 2005). In a 2005 Association of National Advertisers survey of marketers, 40% of the survey's respondents thought there ought to be an industry standard measurement for branded-entertainment deals, but 80% of those involved said they are forging ahead on their own and assessing the impact of their branded-integration efforts themselves (Klaassen, 2006).

Product placement may be one of the few areas where academic research and practitioners' knowledge are at the same level. Despite recent academic research addressing the effects of product placement on consumers (Astous and Chartier, 2000; Russell, 2002), industry practitioners have only recently started to develop tools to systematically assess placements' effectiveness. Many in the industry have been reluctant to adopt any such measures. Product placement agencies do not advocate any form of measurement, thereby avoiding being held accountable for their performances (Russell and Belch, 2005). Many agents simply provide clients with recordings of the final cuts which display the brand as evidence of their work. Some clients have been convinced that it is not possible to get accurate measures; others are simply satisfied with impressions and/or ego involvement objectives.

A number of firms are competing to develop key measurement formulas in an attempt to establish an industry standard. While many of these (Nielsen Media Research, Deutch/iTVX, among others) focus on the monetary value of the placement and/or media equivalencies, others (IAG Research, NextMedium) rely on outcome-oriented assessments including recall, association, and other consumer responses to the placement (Schiller, 2004). Capitalizing on clients' wishes to determine their placements' ROI, companies providing valuation services have proposed a series of factors that should be considered in determining the value of placements. Such factors usually include

placement characteristics (e.g. screen time, character building, etc.), context characteristics (competitive messages, opportunity for distraction), and audience characteristics (size, demographics). Most of the valuation models compute factored impressions as a function of media impressions (Nielsen ratings for TV or box office + video + cable viewership for film) and as a function of the “level” of the placement itself. Such levels are determined based on exposure and potential for recall with more prominent placement and/or auditory placements perceived as better.

Different metrics for measuring effectiveness should be used depending on the objective. The dependent variables proposed range from awareness and recall to demonstrated purchase behaviors. The potential role of placement in the communications strategy depends on the level of integration of the brand in the entertainment content. Whereas simple product placements are often treated as ad hoc bonus branding efforts, more complex branded-entertainment efforts can become the centerpiece of an integrated marketing communications campaign, leading directly to sales. The hierarchy of effects theory provides a useful framework to link placement objectives with their likely impact on consumers and to identify what metric to use to measure that impact. The theory consists of three stages, each focusing on different types of impact on the audience. The cognitive stage focuses on developing awareness and simple product placements, even on their own, can generate exposure for brands. The affective stage focuses on attitudinal effects, the development of positive brand attitudes. Finally, the behavioral stage focuses on actions and purchases. Behavioral effects can be evaluated more readily when placements are combined with cross promotions, using direct response tools.

Given the difficulty in assessing effectiveness, it is also hard to assign a price to a placement. Some attempts have been made at comparing placements to a traditional TV commercial, but that approach has many limitations because the two promotional tools are very different. Others suggest comparing it to publicity and using tools from the public relations arena.

STRATEGIC ISSUES

Lack of control. Getting a brand in the content of a TV program or movie often means that the end result is out of the control of marketers or the placement agents. Even expensive placement deals do not guarantee what the final product will look like. A famous case is the Reebok placement in the 1996 movie *Jerry Maguire*. In exchange for Reebok’s agreement to plan and execute a \$1.5 million promotional campaign, TriStar promised specific in-film placements of the Reebok name and products (Reebok, 1997). When Reebok first read the *Jerry Maguire* script in December 1995, executives loved the story and felt it reflected Reebok’s own philosophy that the basic passion for winning creates the possibility to win. In the draft script initially read by Reebok, Tidwell makes certain negative comments about Reebok. For example, the script included a scene where Tidwell complains that he wasn’t “getting no love from Reebok” and where he “boils down” his Reebok story to Fuck Reebok. All they do is ignore me . . . Always have!” Notwithstanding these negative references to Reebok, the original script contained an uplifting commercial rolling with the end credits. Yet, the commercial was cut and never made it to the final film and, to make matters worse, the film’s disparaging comments about Reebok stayed. As a result, Reebok sued Tristar Pictures for breaking a product placement deal and, although in the end, Reebok won, the *Jerry Maguire* movie with its disparaging comments about Reebok remains.

The lack of control is especially common for placements in unscripted TV programs. Because of the nature of reality TV, marketers do not have complete control over how their product is represented in the show and this can be detrimental to the brand. The lack of control is directly related to the nature of the entertainment industry, where producers do not want to be dictated what their content should include. As a result, some companies are developing their own content outside of the main entertainment content, mainly through digital extensions. For instance, Mindshare, the agency in charge of deodorant Degree’s advertainment, worked in partnership with Fox’s program *24* to create a series of episodes that will be only available

on the web on a Degree-sponsored site. They engaged the show's creative staff and created a new character around which they developed and filmed original stories involving the brand. This ensured that the final content was exactly as suited the brand (Fruitkin, 2006).

Ethical and legal concerns (see SELF-REGULATION; GLOBALLY INTEGRATED MARKETING COMMUNICATIONS; REGULATING ADVERTISING IN THE UNITED STATES).

Product placement is sometimes referred to as *stealth marketing*, because it blurs the line between publicity, the circulation of messages for free in the hope of further dissemination without attribution of source, and advertising, the paid circulation of messages with attribution (Goodman, 2006). It is viewed as problematic because it often conceals sponsorship although the message is actually paid.

Some controversy has arisen over the potential disguise associated with product placement. Gary Ruskin, executive director of Ralph Nader-affiliated Commercial Alert says that advertainment represents the commercial takeover of every nook and cranny of our lives and culture (Lasswell, 2004). The watchdog group filed complaints with both the FTC and FCC, seeking clearer viewer notification of brand embedding. To date, the government has taken no action.

The distinction between editorial content and advertising is especially problematic in news or semi-news programs, where the content is taken as information and the paid relationship is not disclosed to consumers. The potentially hidden nature of advertainment techniques has raised special concerns for young audiences. Although the FCC has strict rules on advertising in children's TV programs, including a limit on the number of spots per hour and a ban on using show characters in ad breaks, it does not have any rules regarding product placement. Of particular concern is the fact that TV shows featuring products linked to obesity, such as sodas and fast food, are among the most popular with children (Edwards, 2006b). Placements for alcohol brands congregate in shows with audiences that skew heavily toward underage viewers.

Product placement falls in a gray area of regulation. Mainly, this is because today's

sponsorship disclosure laws focus on yesterday's technology and fail to operate in the electronic media (Goodman, 2006). The only legislation that can be loosely applied to product placement dates back to when Congress first required broadcasters to identify their sponsors in the 1927 Radio Act. The principle that audiences are entitled to know who is trying to persuade them was continued in section 317 of the 1934 Communications Act. Although the FCC upholds this in rules that say there should be on-screen disclosure of paid-for product placements in TV shows, usually in the end credits, these are not strictly enforced. As a result, advertainment efforts go largely unregulated. The FTC also has regulations in place designed to prevent unfair or deceptive brand communications, especially to children. However, this largely covers advertising and the FTC argues that as product placement does not make "objective claims" about a product, it falls outside these rules and no on-screen advertisement disclosure is required.

Consumer advocacy groups such as Commercial Alert are lobbying for stronger regulation, arguing that the few rules that do exist are systematically violated. They also claim that the line between TV programs and infomercials has become blurred and that product placement is deceptive because it flies under the viewer's skeptical radar. Product placements and script write-ins can be so subtle that viewers fail to identify them as a veiled commercial.

Finally, it is no secret that, in product categories such as alcohol and tobacco, where direct advertising for the product is highly regulated or even illegal, product placements can serve to bypass government or self-imposed industry regulations (Pechmann and Shih, 1999).

THE FUTURE OF PRODUCT PLACEMENT

Estimating the monetary size and scope of the placement industry is a difficult task because many product placement deals are unpaid or undisclosed. However, there is no doubt that it is growing and will continue to grow. The overall value of the global product placement market, including the barter/exposure value of nonpaid placements, grew 27.9% to \$5.99 billion in 2005

(PQ Media, 2006). The growth of product placement continues to significantly outpace that of traditional advertising and marketing and global paid product placement spending is forecasted to continue growing to reach over \$14 billion by 2010 (PQ Media, 2006).

Yet, the relatively high cost of some of the deals combined with the lack of standard measurement tools also points to major limitations to product placement compared to more traditional, and better-understood communication tools. In addition, though the initial rationale was to break through commercial clutter, product placements have now become so prevalent that they too are creating clutter. Instead of being outside the content, clutter is now creeping up inside entertainment content (Edwards, 2006b). This irony has been noted in the advertising industry but, so far, little has been done to limit the amount of product placements in programs. Some executives in the advertainment industry believe that the decline in ratings of heavily branded entertainment programs and the cancellation of some of the major ones, like *The Apprentice*, are in direct proportion to the amount of product placements in them. Although this is a recent and yet a certain trend, some companies, including the major players such as Coca-Cola (Edwards, 2006b), Procter & Gamble, or Unilever (Van Hoffman, 2007), are beginning to react to this new form of clutter by rethinking their marketing initiatives. Product placement will continue to evolve as advertisers look for better and more effective ways to communicate with consumers.

The growth of product placement has led to much speculation and uncertainty over the future of the industry. It has become such a popular tool that there is now talk of reverse placements: brands that would make their debut in an entertainment vehicle and then be introduced to the real world, such as the restaurant chain Bubba Gump Shrimp Company that was created after the 1994 Forrest Gump movie (Wasserman, 2007), or the BMW M5 prototype that was introduced inside a video game to allow people to actually experience the look, the sound, and the handling before there was even a working prototype available (Brand Strategy, 2007).

marketing communication on the Internet

Youngseon Kim and Tina M. Lowrey

Viral marketing refers to a marketing strategy or a marketing phenomenon that facilitates and encourages people to pass along a marketing message to other people, generating the potential for exponential growth in the exposure and influence of the message (Wilson, 2005). This relatively new marketing communication strategy seems to have got its label “viral” from its self-duplicating processes, analogous to the spread of pathological and computer viruses. Viral marketing has also been described as “word-of-mouth,” off the Internet. However, viral marketing on the Internet has its nickname, “word-of-mouse,” delivered or enhanced by the social network channels of the Internet (Zilber, 1991). The formula for success requires an optimal mix of some free web content such as video clips, interactive games, blogs, e-books, and brandable software. This mix should offer valuable information that is ground-breaking, hilarious, or engages a celebrity, a network of people who actually light the fire, and has links that make the content very easy to share (Scott, 2008).

Steve Jurvetson, the venture capitalist behind Hotmail, originally coined the term *viral marketing* to describe how the service grew (Gordon, 2000). Hotmail started its business with viral marketing campaign in 1996: free e-mail. Hotmail users were converted to brand advocates by including a small message in every single e-mail they sent using the service, on the bottom of the note. The message said, “To get your FREE e-mail account go to Hotmail.com.” (Thorne, 2008) The magic of this contagious marketing is that the product is the message carrier. The more you use Hotmail, the more you spread the virus (Gordon, 2000). The e-mail service spent only \$500 000 on marketing to garner 12 million subscribers in a year and a half.

The form of viral marketing does not need to be sent as an e-mail. It can be as advergaming, images, video clips, or text messages. YouTube, Facebook, MySpace, Twitter, and so on, are all good examples of venues for viral marketing. Videos are posted for all to see and anyone can forward a particularly liked clip to his or

her own social network. Thus, viral marketing on the Internet is said to be the single most empowering and effective communication tool today (Scott, 2007). Undeniably, more and more marketers use this marketing magic (Thorne, 2008). However, a lot of marketers fail in getting their messages to be viral. The reason is that they do not understand fully how to create the content of viral marketing on the web, but instead still follow the rules of traditional marketing communication. Unlike advertising in traditional media which is expensive, the best word-of-mouse campaign inexpensively delivers content on the web in order to promote a marketer’s organization and its products (Scott, 2008). The content should be directly connected to the company’s products, services, and/or ideas. Viral marketing on the Internet is not a gimmick. Its success comes from self-replicating web content that people voluntarily share with their friends, colleagues, and family members.

The reasons that marketers increasingly include viral marketing as part of their integrated marketing communications are the power and cost-effectiveness that it offers. Viral marketing on the Internet is not a traditional top-down marketer-to-consumer communication, but instead takes a nonintrusive bottom-up approach, where consumers are in control of whether to interact with the communication message (Kirby, 2006). The user-driven process can ultimately help the marketer to achieve exponential brand endorsement by influencers and consumers. The cost-effectiveness of viral marketing on the Internet means that it provides accountability when tracked, thus measuring and proving ROI, and can even provide an increasing ROI (Kirby, 2006). In addition, it has no fixed cutoff point as long as the message remains contagious on the web. In conclusion, viral marketing has become an integral element in the overall marketing communication mix.

opportunity identification

Henry Robben

INTRODUCTION

What is opportunity identification? Some authors would simply state that it is about getting ideas for new products (NPs) (Lehmann and Winer, 2005). In fact, it resides in the first phase of the process of NP or service development (SD), which consists of several stages or phases, varying in numbers depending on the source selected. It is strategic in nature, and “is the most difficult to describe or define” (Crawford and Di Benedetto, 2006, p. 28). As such, it is qualitative, informal, and approximate in nature rather than quantitative, formal, and precise (Kim and Wilemon, 2002). Most companies favor opportunity identification in advance of concept generation so as to demarcate the arena for the rest of the NP/SD process. However, others prefer opportunity identification to follow concept generation so as not to bias any directions in decision making (*see* CONCEPT TESTING).

Opportunity identification belongs to the so-called “fuzzy front end” (FFE) of the NP/SD process. Managers may find the FFE the weakest link in their innovation processes (*see* FRONT END OF INNOVATION). This first phase receives input from several activities, such as ongoing marketing and corporate planning and special opportunity analysis (Crawford and Di Benedetto, 2006). The result should be the identification of a number of opportunities through a creative process. Despite its recognized importance, little research has been devoted to the first phase in innovation management. Therefore, this process is not fully clear, as typically it is nonroutine, dynamic, and uncertain, but it concerns collecting business opportunities that could realistically be developed by an organization into successful products or services (Trott, 2008). Opportunities may arise from an underutilized resource (e.g., excess production capacity), a new resource (e.g., new skills or technologies), an external mandate (new regulations, a customer problem, a market threat or opportunity), or an internal mandate (e.g., Steve Jobs’ ambition to “reinvent the phone” through the iPhone project)

(Crawford and Di Benedetto, 2006). Opportunity identification, in fact, is the creative process by which an organization recognizes and assesses such opportunities. To be effective, it should be preceded and guided by a clearly formulated product strategy, for instance, a product innovation charter (Crawford and Di Benedetto, 2006), which basically sets out the strategy for opportunity identification. The product innovation charter provides focus on opportunity identification in the following ways:

- It provides a background: what are the reasons for developing a new offering? Which analyses have been done, and with what results?
- It necessitates focus: we need to describe and specify at least one technology and one market dimension.
- It specifies goals and objectives, for example, in terms of profit, growth, or market status.
- It identifies special requirements or guidelines, such as the innovativeness of the offering and the timing of market entry, possibly along with other guidelines, like an emphasis on avoiding a company’s weakness.

Opportunities need not be restricted to a product or service concept. Kahn (2001) suggests new insights, new technology, or new customers can also be opportunities. As such, opportunity identification defines the hunting ground for further exploration. The process may differ depending on the size of the organization (e.g., large MNC versus a single branch), product type (e.g., FMCG, services, B2B versus B2C), and the strategic role of the product or service (e.g., breakthrough, incremental innovations).

RELEVANCE

What companies are looking for are markets that are attractive – in terms of size in units and value, growth rate, profitability – with an opportunity to create a competitive position in one or more segments. The idea identified should therefore match the company’s strengths and capabilities. The front-end activities result in the product concept (clearly aligned with customer needs), the product definition (explicit and stable), and

2 opportunity identification

the project plan (priorities, resource plans, and project schedules).

Opportunity identification becomes especially relevant for industries such as pharmaceuticals. Investments are high, payoffs uncertain, and chances for differentiation are not easily obtained. Such industries experience the need to absorb much risk in the early phases of development (Bonabeau *et al.*, 2008). Proof of concept – an indication that the new product may be effective – is therefore needed for the idea to move on to the next phase in the new-product development process. The costs for moving an idea through the early phases of NP/SD are 1/5 to 1/50 of those for moving one through later stages.

For most organizations, it will not be possible to exploit all identified opportunities. That is why they need ongoing strategies covering NP/SD to systematically derive relevant criteria to judge the opportunities. Such criteria might include “do customers care, do we care, can we do it, can we stay ahead, or match the competition” (Griffin, 2000). Such criteria are necessary to assess the market or customer evaluation for new products. In essence, the process is the same for new-to-the-world products and close-to-home extensions. This part of the NP/SD process may also be referred to as “*a truth-seeking early stage, focusing on evaluating novel products’ prospects and eliminating bad bets*” (Bonabeau *et al.*, 2008). As such, it tries to reduce uncertainty about a new product’s or service’s market promise quickly and effectively.

This reduction in uncertainty is a necessary step in a systematic process. In new-product decision making, managers can make several errors in judgment. They may ignore evidence challenging their assumption that a project would succeed for different reasons such as a shared belief that the new product will work. They also may terminate a project for lack of evidence that it could succeed. This may occur when a firm does not conduct adequate research or testing. Typically, many organizations focus on the later stages in development, when market introduction is near and management’s attention is drawn by the costs of launching the product or service. This focus may in fact enhance the occurrence of both errors, as they neglect the importance of early testing.

CREATING NEW OPPORTUNITIES

The literature suggests many ways to generate new ideas that potentially create opportunities for companies. Trott 2008, for instance, identifies existing products, competitor’s products and reverse engineering, technology, unexploited patents, customers and vendors, the sales force, senior and top management, brainstorming and other creative techniques, and individuals as sources for potential new business ideas (*see* CREATIVITY; BRAINSTORMING). Moenaert *et al.* (2009b) add to this a list of varying sources, like identifying underserved, overserved, or unserved market segments, listening at conferences, hiring consultants of competitors, and the analysis of garbage. Björk and Magnusson (2009) suggest that the better people are connected in a network, the higher the quality of ideas generated; interaction with other individuals increases the number of valuable new-product ideas.

An obvious source for new opportunities is the current customer, who may voice ideas for new features or benefits, or complain about an offering’s current performance. Noncustomers or nonusers also form a source of new opportunities, as Nintendo’s Wii game console shows: it was designed for people who were not interested in playing “traditional” computer games. Alternatively, a company may investigate a customer’s value chain in terms of their consumption and production processes. Any inefficiencies or ineffectiveness identified may lead to a new business opportunity. Employees also form a source of new ideas, be they from R&D, manufacturing, sales, or intelligence units. Checking the competitive landscape for new opportunities may reveal competitors’ actions or intentions, thus creating a sense of urgency for counteraction. For each of these sources, there are many creative ways to help come up with new opportunities, brainstorming being a classical example (*see* IDEA MANAGEMENT).

ASSESSING NEW OPPORTUNITIES

In assessing new opportunities, we try to differentiate between potentially successful ideas and those that are not: “*The challenge is to separate the real opportunities from the illusions*” (Goold and Campbell, 1998:130). That is why

a new-product idea in fact faces two screens in the early phases. The first one controls whether an idea begins the phase or not. The second concerns whether the idea ends the FFE. In essence, one wants to manage two types of errors. A type I error occurs when a possible success is rejected; this may happen in rigid evaluation processes. A type II error occurs when failing to reject a possible failure; in this case, the evaluation process is weak. Ideally, we want to reduce both kinds of errors through our assessment of business opportunities.

Recent research suggests that managers evaluate business opportunities or strategic market options on the basis of four criteria (Moenart, Robben, and Gouw, 2009a). These criteria are business opportunity, feasibility, competitiveness, and leverage. The first three criteria are must-haves, the latter one is a nice-to-have criterion.

Business opportunity. The first criterion involves the *business opportunity*, that is, the economic rent the manager expects to gain from the investment. In the eyes of the decision makers, business opportunity is the prize to aim for. This prize can contain a number of elements and have results for the short, medium, and long terms: increase in market share, increase in customer share, access to new markets or distribution channels, maintaining or increasing prices, increasing margins, increasing the efficiency of business processes, increasing the appropriability of revenues, increasing the economic value added, and so on. More precisely, each option represents a chance to create business or improve efficiency, or a combination of both.

Feasibility. A second dimension concerns *feasibility*, that is, the degree to which the proposed option is expected to be possible, in economic, technical, and organizational terms. Managers consider feasibility, together with opportunity, as the key criterion in judging strategic market options. Strategic projects often involve important changes in assets, know-how, and core processes. Such investments hence carry a high degree of organizational risk. Decision makers assess the feasibility of a strategic option on (i) its

alignment with corporate strategy, (ii) the resource requirements, (iii) the flexibility, and (iv) the quality of the team that proposes the strategic option.

Competitiveness. The third dimension relates to the *competitiveness* of the proposed strategic option, that is, the relative strength of the proposed new product as compared to the offerings of other firms in the industry. The competitiveness dimension consists of three key elements: (i) to what extent does the proposed option offer a competitive answer to the identified threats and opportunities; (ii) how big is the advantage over the competition the company seeks to develop – is it incremental or game changing? and (iii) how sustainable is the proposed option – how fast can a competitor come up with a similar solution?

Leverage. The leverage of a strategic option involves the expected likelihood of positive spillover effects. Such spillover effects may involve business leverage in other business units belonging to the same company (e.g., other business units producing similar products on the basis of a new platform). However, spillover effects may also result from future spin-offs that follow from this investment within the same business unit (e.g., a new-product platform enables a low-cost solution in the long run). Positive spillovers are “nice-to-have” factors that senior executives are likely to consider when making investment decisions. Leverage effects may be viewed as “outbound” synergies. It is crucial then, to adopt a realistic perspective on such leverage effects.

Moenart, Robben, and Gouw (2009a) showed that ex-ante, feasibility and business opportunity dominated the decision-making process of managers, whereas ex-post the competitiveness of a new business idea appeared an important determinant of new-product success. Assessing strategic options is a process that requires inputs from different functions in the company. Analyses where financial data are lacking, or those where there is insufficient input from say, manufacturing, tend to be shallow. From experience we can tell that the quality of the assessment improves with the assessors having done

4 opportunity identification

up-front data collection and analysis. Typically, senior management may play a stimulating and facilitating role in preparing the assessment process. Following this analysis, an investigation into IP, finance, and judicial matters can proceed.

The logic behind this assessment procedure is compelling. If the assessors determine that there is a business opportunity, that it is feasible, and that it creates a competitive position, the odds are that this particular option moves to the next phase. Options that do form a business opportunity, but are not feasible, or are not competitive, cannot add value to the company. An option that is also useful in other departments or markets or in the future, is a nice-to-have. It is not vital to new-product or -service success, but it may add a certain synergy among the company's NP/SD process.

There are many alternative evaluative mechanisms, for instance, the opportunity/threat matrix (Kotler and Keller, 2009). Two suggestions may be valuable in this respect. First, the criteria used for evaluating strategic options or business opportunities need to be unambiguous and formulated before the evaluation process starts. This formulation prevents unclarity from entering the evaluation process, making the assessment invalid. Second, following conventional wisdom that "all models are wrong, but some are useful," an assessment team should adapt existing models or build new ones to cater to the company's specific needs. Using standard models may ease the comparison with competitors, but to win new markets or customers, one needs to be different from or better than the competitor. Although the process of opportunity identification may seem like a generic component in the NP/SD process, companies should adjust it to suit their needs.

At the end of the evaluation of strategic options or opportunities, the assessing team has a systematically evaluated set of opportunities. This set can now act as an internal quote to a company's management to further pursue the evaluated opportunities in the NP/SD process, or as an external quote to venture capitalists, to acquire additional funds for further development. The next phase of the NP/SD process seeks to refine the results obtained, to refine the market definition, and to analyze promising opportunities into more detail, so as to come up

with a product concept in terms of customer need description, form (physical representation for products or delivery mode for services), and the technology to create this form.

CONCLUSION

Most publications cite the phase of opportunity identification as a creative yet difficult-to-manage process. The issue at hand is not the generation of ideas. For this, we have many sources or techniques available. Once a pool of ideas (or opportunities, or strategic options) is formed, it is vital to choose the most promising opportunities among the ideas generated. To this end, it becomes important to use relevant and clear criteria to assess the viability of each idea. These criteria need to be defined early in the process, and be based on, for instance, a product innovation charter (see GROWTH STRATEGIES).

product design

Robert W. Veryzer

DEFINITION OF PRODUCT DESIGN

The phrase *product design* can refer to either the process of creating a product or the embodiment of a created item (a “product design”). Product design involves idea generation, concept development, and formulation that spans a number of considerations as well as knowledge or expertise domains – human needs, problem solving, synthesis of technology, ergonomics, manufacturing processes, environmental concerns/sustainability, market viability/acceptance, engineering, industrial design, marketing, and so on. The designing and designs of products to be manufactured and produced in quantity typically involves collaboration (*see* CROSS-FUNCTIONAL TEAM) among specialists from various disciplines such as engineering, industrial design, research and development scientists (*see* RESEARCH & DEVELOPMENT), market researchers, as well as others (Veryzer, 2005b). The aspects of design focused on by the various disciplines involved in producing (designing) a product design differ widely. For example, engineering design focuses more heavily on the function of a product and the means by which that functionality is delivered (e.g., mechanism) than does industrial design, which focuses more on product-use experience, user-product interfaces, ergonomics, functional enhancements, and concerns about aesthetics. Marketers are typically concerned with identifying and understanding market opportunities as well as collecting information from or about likely customers or users that will help shape a product’s design (*see* LEAD USERS; VOICE OF THE CUSTOMER). They also focus on developing a strategy or program for ensuring a product’s commercial success (*see* GROWTH STRATEGIES; NEW-PRODUCT FORECASTING), and the decisions that this entails frequently affect a product design in the form of “constraints” (e.g., size, weight, colors, desired product positioning, and price points). Although each of these disciplines may contribute to the overall product-design effort, they have disparate approaches and

focus on different – yet often interrelated – product-design concerns (Veryzer, 2005b).

TRANSLATION OF NEEDS INTO PRODUCT DESIGN

Product design fundamentally arises from a problem or difficulty to be solved or a need or desire to be met. Although the front end of a product-design effort encompasses OPPORTUNITY IDENTIFICATION and analysis, as well as idea generation and selection, inspiration for a design, as well as the idea(s) for a design, may come from various sources (e.g., observations, nature, and toys), or in various ways – addressing a need/necessity, thoughtful contemplation, accidents, serendipity, and so on (*see* CREATIVITY). Regardless of the path by which product design is generated, a deep understanding of the problem or need (or desire) is crucial to both the product-design effort and the ultimate success of a product design. An understanding of the problem or need (or desire) to be addressed yields the core or key benefit(s) the product (design) is to provide for the person, group, or business for which it is being designed (Urban and Hauser, 1993; *see* VALUE PROPOSITION). Sometimes, discerning the dimensions of a problem or need (or desire) is relatively straightforward through observation, questioning, and trial; however, customers do not always know what they want, or are unable to sufficiently articulate what they actually need. Even though the underlying structure or dimensions of a need are not always readily identifiable or explicit, this does not discount the importance of gaining a deep understanding of both the problem/need and the consumer – through extended observation and in-depth study when necessary – as an important foundation for product design.

In interpreting and translating needs into designs, an understanding of the dual nature of many product designs both as a physical entity and a psychological/mental identity is essential for developing a complete and ultimately successful product design. This requires attention to a number of aspects of product design including product identity, usability, ergonomics, image, form, emotional appeal, and aesthetics, and these extend even to

2 product design

hedonistic and psychological drives relating to self-image/self-esteem, desire, and sensuality (Veryzer, 2000). Woven throughout such considerations are currents of culture and fashion, along with more seemingly direct aspects of a product design like price and value – which may also have symbolic dimensions or meanings.

Along with a deep understanding of the problem, need, or desire, it is also necessary to have an appreciation of the elements of a design and the constraints relating to them. Product designs may be thought of in terms of the function(s) for which a product is being designed, requirements and constraints (specifications as to how the product must deliver the desired function – *see* PRODUCT SPECIFICATIONS), design parameters or vectors of potential design solutions that can deliver the desired functionality while satisfying the requirements and constraints, and constituents or the parts and assemblies (components) that are to make up the product design. Various methods such as house of quality or quality function deployment (QFD) may be used to structure the task of translating customer demands (needs) into design targets (*see* QUALITY FUNCTION DEPLOYMENT (QFD); CONCEPT SELECTION MATRIX).

DESIGN COMPOSITION

In terms of specifying the product design, several dimensions should be considered. The first is the function of the product and how that functionality is to be safely delivered; the second is constituent or essential parts; and the third is positioning, inclusive of (product) identity, emotional appeal, and differentiation from other product offerings.

A product's configuration or *architecture* as it is sometimes termed, which addresses delivery of functionality(ies) by determining the necessary components and their layout, begins to emerge during the concept-development phase in sketches, function and component diagrams, as well as in early prototypes (Ulrich and Eppinger, 2008, p. 167; *see* PROTOTYPE). Technology (*see* TECHNOLOGY S-CURVE) may, in part, determine this, as does the degree to which the product or product category

is established or has conventions. Product architecture may be thought of as a continuum ranging from completely integrated (intertwined parts) to individual, easily separated parts. In designs employing an “integral” architecture, functional elements of the product are highly interrelated and overlapping, and thus the boundaries between parts, components, and subassemblies are often difficult to identify or separate (Ulrich and Eppinger, 2008). In design executions employing a “modular” architecture (*see* PRODUCT MODULARITY), functional elements (parts and mechanisms) implement one or very few of the functions the product performs. The independence or “separability” of the physical elements of a product (design) usually makes it relatively easy to effect changes with respect to one aspect (part or function of a product design) without affecting other elements that make up a product. Product architecture can have significant implications for a product design on various dimensions. For example, for a particular instance, a highly integrated approach to product design may result in reduced assembly and manufacturing costs. Likewise, a modular approach to a particular product design might be used to provide cost and manufacturing efficiencies by using a common product platform (*see* PRODUCT PLATFORMS) as a basis for multiple product offerings. Product-design configuration has implications for the consumer or user as well as manufacturers. For example, a modular approach may lend itself to being easily upgraded, add-ons, adaptations or customizing, servicing, and even reuse of components.

The constituents vary according to what is suitable and required for a given product category (e.g., materials, fasteners, system components, switches, software, and finishes); these are virtually unlimited in terms of the possibilities and the different ways in which they may be configured. With the advances in electronic and digital technologies, there is greater latitude in configuring a product (design) than ever before. Beyond the direct concerns relating to the elements of a product design, the composition and configuration should take into consideration factors such as costs, manufacturability, available and standard components, available

materials and resources, manufacturing facilities, and manufacturing–product environmental impact (sustainable design).

A product design assumes an identity or “positioning” in the minds of those who encounter it (see PRODUCT POSITIONING). In other words, by design or default, people perceive a product design as conveying a meaning (e.g., “new,” “efficient,” “durable,” “cheap,” “fast”). There are a number of factors that may contribute to how a product is perceived and judged. These include aspects of a product design such as aesthetics, usability, performance, price (due both to customer resources as well as price–quality inferences), environmental impact, familiarity of the product form (as well as the product category), emotion(s) evoked, the degree of differentiation from competitors’ product offerings, the novelty of the (product design) embodiment, and the degree to which the product is innovative or new. The task of creating a design identity or product position can be further complicated by dynamic factors such as fluctuating technologies, globalization (see GLOBAL PRODUCT DEVELOPMENT), cultures, trends, fashions, and images, which play a considerable role redefining products and product categories over time.

PRODUCT DESIGN STRATEGY

Pursuit of marketplace objectives (profitability, market share, solving a difficult or previously unsolved problem, etc.) beyond the pure function(ing) of a product can play a substantial role in shaping a design (see COMPETITIVE ADVANTAGE). There are several fundamental product–design strategies that may be pursued in creating a product design (Veryzer, 2005a).

- *Cost/price advantage strategy*: emphasis on design so as to minimize component and production costs, thus affording a strategy of price domination.
- *Design eminence strategy*: establishing an identifiable and unique product image using, primarily, ergonomics, innovative concepts, and aesthetics so as to significantly elevate the product offering above the competition.
- *Feature leadership strategy*: pursuing new solutions and pushing the frontier in apply-

ing or developing technology (see DIFFUSION OF INNOVATION; INNOVATION METRICS; RADICAL INNOVATION).

- *Specific appropriateness (or concentration) strategy*: focusing on design that delivers the optimal product for a narrow product space (e.g., product category or the requirements of a particular type of user).
- *Desirable alternative strategy*: executing design consistent with an established product category or category leader but with sufficient variation to offer an attractive alternative choice.

In effect, each of the strategies involves or may result in a “position” for a product – for example, low cost, performance leader, most beautiful, preferred alternative, leading edge, and so on, and the position created by the design (composition) plays a key role in the marketing and promotion of the product. These strategies are applicable across design situations (see PRODUCT LIFE CYCLE) involving existing product bases (renovative and adaptive design), or new product formulations (e.g., evolutionary and discontinuous design).

CONSIDERATIONS FOR PRODUCT DESIGN (PROCESS)

There are a number of important considerations for product design and the product–design process, some of which are discussed in the following.

Expertise required.

- Various kinds of expertise are needed to delineate a product design and reconcile the inherent trade-offs (see INTEGRATED PRODUCT DEVELOPMENT). These range across such disciplines as engineering, industrial design, marketing research/marketing, and others; and encompass areas involving customer/market perspective, understanding culture(s), understanding user needs, opportunity analysis and product/market viability studies, product definition, concept generation, concept sketches, domain-specific principles, engineering (e.g., mechanical and software engineering), materials evaluation,

4 product design

prototype development, product-use experience, aesthetics, interface design, human factors/ergonomics, emotional appeal, safety assessment, testing with customers, market confirmation, and manufacturing processes.

- The roles (market research, engineering, industrial design, marketing, etc.) may sometimes become blurred either because of various design team members being aware of the importance of considerations usually handled by someone from another discipline (this is usually constructive and beneficial to the design process and the product-design outcome), or when a (design) team lacks the expertise of one or more contributing disciplines (e.g., this has been observed in discontinuous innovation product-design settings where the process is often heavily R&D driven).
- There are numerous specialized product-design professionals who may be involved in the design process; they may be specific to particular design forms, industries, and product categories (e.g., automotive design (exterior design, interior design), graphic design, computer graphics design, appliance design, and toy design).

Design process.

- The product-design process may vary depending on the specific design and marketing goals; however, typically, the process involves (i) opportunity definition (with a deep understanding of the problem, need, or desire motivating the design effort); (ii) concept (solution) generation/ideation (see BRAINSTORMING), exploration, and development; and (iii) selection of design solution (see IDEA MANAGEMENT) and refinement (involves constructing product representations and prototypes; see PROTOTYPE; PRODUCT TESTING). Concept-confirmation research with target customers is usually conducted at various points throughout the process (see CONCEPT TESTING).
- The product-design process is usually iterative, subject to periodic evaluation and refinement of the emerging product design (see THE STAGE-GATE IDEA TO LAUNCH SYSTEM).

Market viability.

- Marketing activities directly related to product design tend to progress from market/opportunity definition to customer research (e.g., focus groups, and perceptual maps), to concept testing and product-design validation (with customers/users), test marketing, and eventually on to activities less directly related to the product-design effort such as product launch planning (e.g., determining appropriate promotion and advertising programs; see LAUNCH STRATEGIES).
- There are a number of marketing-related product-design goals. These involve design for speed to market, design to lower price (e.g., reduce costs, facilitate ease of manufacture, and use of common or easily adaptable platforms), design for identity (differentiation, positioning, brand, and corporate identity), universal design (to make a product design appropriate and usable for the broadest possible range of consumers), social-responsibility design (a desirable objective that is increasingly becoming an attribute sought by consumers), and marketing strategy compatibility (e.g., compact design so as to facilitate easy and low-cost distribution).

radical innovation

Gina Colarelli O'Connor

DEFINITION

Radical innovation (RI) has been defined previously as innovations that offer either new-to-the-world performance features, or significant improvement (5–10 times) in known features or significant reductions (e.g., 50%) in cost, such that new application domains become possible (Leifer *et al.*, 2000; O'Connor, 1998). Technology, either newly discovered or in unique combinations, typically enables the innovation, and is recognized increasingly as the basis of the competitive advantage (Garcia and Calantone, 2002; Hill and Roethaermel, 2003; Lynn, Morone, and Paulson, 1996). RIs transform existing markets or industries, or create new ones. By this definition, computerized tomography (CT) and magnetic resonance imaging (MRI) were RIs in the field of diagnostic imaging, whereas the subsequent incremental and generational improvements in these technologies were not. The first personal computer was an RI, as it defined a new industry. Likewise, pagers and cellular telephones were RIs when first introduced.

RI is accompanied by high levels of uncertainty because, to achieve these performance leaps, firms must expand to incorporate or create emergent customer markets and/or new technology competencies. Each requires new knowledge or departure from existing skills or familiar practices and relationships (Christensen, 1997; Hill and Roethaermel, 2003; Levinthal and March, 1993). This not only triggers market and technical uncertainties but, also resource and organizational uncertainties (Leifer *et al.*, 2000). The eventual commercial success of RI opportunity is also highly uncertain. This, coupled with the enormous investment requirements to build new technical or market competencies given the novelty of the innovation for the firm, makes managing RI a highly risky endeavor, but one that promises the corporate renewal sought by large established firms.

Garcia and Calantone (2002) have criticized scholars for muddying the definitional waters

regarding innovation. They call for a three-level typology of innovation, rather than the simplistic radical-incremental dichotomy that is so often used (*see* INNOVATION TYPOLOGIES). In fact, a survey of terms used in the industry reflects this three-level approach. Table 1 presents a variety of vocabularies used by firms today to reflect their experiences with innovation: most consider three different levels.

Garcia and Calantone (2002) develop their typology of innovativeness on the basis of micro (firm) and macro (market or industry) levels of impact as well as the presence of technical and market discontinuity, and define *radical innovation* as an extremely rare class of innovations that cause disruption at both the firm (micro) and the industry/market (macro) level, and that require new market creation and novel technology discovery. Their second category, *really new innovation*, which they describe as much more common, exhibits macro level discontinuity on *either* the market or technical dimension and *either* market, technical, or both types of discontinuity at the micro level. In whatever manner one might choose to classify these, what is clear is that both “really new” and “radical” innovations share a characteristic that incremental innovation does not – that of high levels of uncertainty on multiple dimensions. Incremental innovation is based on technology improvements along predictable trajectories, and is targeted toward a market that is familiar to the company. It relies on speed of execution and customer intimacy. But by definition, the other two categories require organizations to move into uncharted territory, where reliance on experience, current knowledge assets, and loyal customers are not an advantage. Radical and really new innovations require situation-specific knowledge and willingness to evolve business models to reflect new markets that are created. Both types may cause the firm to face issues not just of technical and market uncertainty, but organizational and resource uncertainty as well. The dynamics of competition change as well.

Companies do experience “really new” innovation much more frequently than RI, but the management challenges are of like kind, owing to the firm’s inability to rely completely on current technology competencies and current customers,

Table 1 Terminology used by firms to describe levels of innovation.

| <i>Terminology Used</i> | <i>Companies</i> |
|--|-----------------------|
| Horizon 1, 2, 3 | IBM, 3M |
| Incremental, platform, breakthrough/radical | Gerber Scientific |
| Today, tomorrow, beyond | Corning |
| Incremental, major improvements, step-outs | Sealed Air |
| Incremental, substantial, transformational | J&J Consumer Products |
| Business unit projects, CEO projects, advanced technology projects | GE |
| Aligned, white spaces, grey spaces | Air Products |
| Quadrant 1,2,3,4 (alignment vs. time horizon) | Kodak |
| Incremental, platform, scope change (Charles River) | Mead-Westvaco |
| Incremental, gamechangers | Shell Chemicals |

and the need to learn, redirect and reformulate given these uncertainties. The difference between “really new” and “radical,” is one of degree (i.e., uncertainties may exist on more dimensions for “radical” than for “really new”), and so, for purposes of this article, they are taken together, and considered as “major” innovations. The difference between these two forms of “major” innovation and the incremental innovation is one of kind: managing for innovation in which uncertainty levels are high requires approaches that differ from those used when previous experience is of value and uncertainty levels are lower.

Another perspective used to define RI is the nature of its impact on the world of competition. Utterback, (1994) defines RI as that which introduces discontinuity into industry dynamics, leaving incumbent firms’ investments in technical skill, knowledge, designs, plant, and equipment no longer providing competitive advantage. The effect is to dislocate incumbent firms from their leadership positions and completely restructure industries on the basis of innovations offered by outsiders. IBM’s commercial success with the electric typewriter unseated Olivetti and other industry players in the manual typewriter industry. In the lighting industry, oil lamps displaced the use of candles, but were themselves displaced by gas lamps, then electric lamps, fluorescent lamps, and now halogen lamps. Each wave of change unseated the industry leader, with the exception of GE with their successful adoption of fluorescent technology.

Chandy and Tellis, (1998) note that most definitions of RI share the commonality in (i) the extent to which the product incorporates a new technology and (ii) the extent to which it brings dramatic increases in value to the marketplace relative to current solutions. An RI is an offering that is high on both the technology and market dimension. A market breakthrough may bring dramatic increase in benefit to the market without novel technology. A technological breakthrough may use substantially novel technology without change in the perceived value in the marketplace.

Sood and Tellis, (2005) question the definitions that rely on market impact and instead focus on novelty of the technology. They suggest that defining an innovation in terms of its effects rather than its attributes is circular, and revert to defining platform innovation, instead, as the emergence of a new technology based on scientific principles that are distinctly different from those of existing technologies. While their arguments regarding tautology are important, one must consider the level of analysis one is examining. Perceived, if not real, market impact is a critical component of the definition for those studying management practices associated with RI, particularly where market discontinuities are expected to occur.

Christensen (1997) notes that RIs may be either disruptive or sustaining. In either situation, they are defined as offering new-to-the-world performance features or dramatic improvements in a key feature of interest.

All of these perspectives share the following common elements:

1. *Immense learning and novelty for the firm leading the commercialization effort:* This requires leveraging current competencies but, more importantly, developing new ones, on both the market and technical dimensions. It requires different management systems that are aligned with an innovation objective and a recognition of uncertainty and ambiguity. This also impacts their strategic focus, and may force decisions about the company's strategic intent, that is, its investments for the health of the organization in the distant future.
 2. *Disruption of competitive dynamics:* Established competitors may not be the key competitors; rather, firms and technological approaches that are external to the firm's current competitive set may become prominent figures.
 3. *New market formulation:* Agents that never previously participated may be required to join the value network, the ecosystem of participants necessary to bring the innovation to fruition. This may require external incentives for them, given the uncertainty of the market opportunity.
 4. *Changes in consumer behavior:* Most RIs require the adoption of new usage techniques, and therefore an investment in learning, on the part of buyers.
- What marketing and entrepreneurial inter-firm practices are required for successfully commercializing RIs. What practices diminish the barriers to such success?
 - What practices can firms and other institutions take to create new markets?
 - How will marketing professionals span the boundary generated by the increased need for interfirm partnerships in finding breakthrough opportunities and commercializing them?
 - What can be learnt about diffusion of RIs and about what impacts market take-up rates? Price has been examined, but what other phenomena influence the take-up timing and rate?
 - What are the competitive dynamics for RI in comparison to conventional fast-paced development cycles?
 - What is the role of an organization's market power in an industry in suppressing and/or elevating RIs?
 - What influences consumer behavior in the adoption of RI?

INDUSTRY LEVEL ANALYSES OF RADICAL INNOVATION

At the industry level of analysis, work has centered on understanding technological evolution and the role of RI, irrespective of whether an economic advantage exists for pioneers of RI, and the impact of specific competitive dynamics (e.g., price) on stimulating markets to adopt RIs.

RADICAL INNOVATION AND THE FIELD OF MARKETING

The phenomenon of RI is rife with marketing issues. It is therefore important for marketing scholars to engage in research to deepen their understanding. Points of intersection between RI and marketing may include seeking answers to the following questions

- How do firms recognize opportunities for breakthrough innovation (BI), given the lack of an identified market a priori?
- What approaches work best for learning about markets that do not exist?

Technological evolution and RI. The literature describes a technology as evolving through an introductory period of slow growth as it becomes better understood and more researchers become aware of it. This is followed by a period of fast growth as the scientific understanding passes a threshold and a dominant standard emerges around which numerous product platforms can be defined (see PRODUCT PLATFORMS). Finally, after a period of improvement the technology reaches a mature stage when a ceiling or plateau in improvement is reached, and the focus of innovation shifts from product to process innovation (Utterback, 1994).

Graphically, this phenomenon is represented by an S-curve.

Recent works by Sood and Tellis, (2005) find that this widely held theory is not confirmed in a number of cases they empirically examine. Rather, they find that distinctly novel or “platform” technologies evolve through an irregular step function with long periods of no growth in performance or technological improvement, followed by performance jumps. Thus, multiple S-curves may be a more appropriate explanation of technology evolution than one singular curve (*see* TECHNOLOGY S-CURVE). Additionally, contrary to previous research (Christensen, 1997), Sood and Tellis find that the performance curves of two rival technologies may experience more than one point of intersection, and rivals may successfully attack from below a leader’s performance trajectory. Thus, the final status of each technology cannot be determined from the direction of the attack or timing of introduction. Novel technologies are introduced as much from new entrants as from large incumbents. The rate of technological change and the number of new technologies increase over time within any new technology platform. Additionally, each new technology introduces a set of secondary dimensions as a new basis of competition. Practically, these results suggest that premature abandonment of investments in novel technology may occur for firms persuaded by the S-curve theory.

Pioneering and radical innovation. While much of the work in marketing regarding pioneer advantage is based on products that may be new but not necessarily radical, some attention has been paid to pioneering with advanced technology or “really new” products (Min, Kalwani, and Robinson, 2006; Bayus, Jain, and Rao, 1997; Klepper and Simons, 1997). The results of these studies, while conclusive individually, lead to contradictory results collectively (*see also* FIRST-MOVER ADVANTAGE). The question of enduring market superiority for RIs, therefore, cannot be predicted solely by order of entry.

Min, Kalwani, and Robinson (2006) posit that extremely high levels of market and technical uncertainty faced by pioneers of really new products (in contrast to pioneers of incremental innovations) make survival risky. They demonstrate

that 23% of market pioneers of really new industrial goods survived at least 12 years, compared with 61% of market pioneers of incremental innovations. Market pioneers creating really new products must also create new markets, face resistance, and manage technical uncertainty not experienced by market leaders for incremental innovation. Fast follower survival rates did not differ significantly, however, for really new versus incremental innovations, at 38 and 39%, respectively. Early followers benefit from the prior efforts of pioneers in building primary demand for really new products, learn from the pioneers’ efforts to help customers articulate latent needs, and to leapfrog the pioneers’ technical solutions.

Bayus, Jain, and Rao (1997) offer a more complex story in their study of the personal digital assistant market. An historical examination of market entrants and their differing product design decisions lead the authors to conclude that pioneers and early entrants rushed to market with a klugey device hoping to capture a mass market at the outset. Later entrants, however, focused on niche applications, introducing devices that were fully functional and specifically designed to meet the needs of the specialized markets they had targeted. Initial entrants’ performance was dwarfed by that of later entrants. While the authors suggest that early entrants offered “too little, too early” one wonders what would have happened if they had not stimulated market interest with those initial devices.

A final study offers insight into the link between major innovations and early market entry. Klepper and Simons (1997) suggest that long-term survivors of industry shakeouts are those who entered early and who invested consistently in R&D such that they offered first and subsequent innovations, in both product and process. They find evidence of increasing returns to R&D, indicating that those who invest early in innovation and continue to do so subsequent to their initial entry dominate competitors over time. This conclusion, in conjunction with Tellis and Golder’s (1996) observation that those who endure as market leaders exhibit vision, commitment, persistence, and continued investments in innovation brings some reality to the

quest for the silver bullet of the role of first entrant that researchers continuously seek.

Pricing and radical innovation. The scholarly work on causes of sales takeoff for really new products emphasizes new-firm entry or declining prices as key determining factors (*see also TAKEOFF*). Bayus, Kang, and Agarwal (2007) examine whether price declines occur because of monopoly profit maximization behavior in the early stages of a new market or because of competitive pressures unleashed by firm entry. They study 30 successful consumer and industrial product innovations deemed significant by a panel of experts in the field over a 125+ year period of time, and conclude that, in contrast to other studies, price declines are not direct causes of industry takeoff, determined by strategic choices made by market pioneers, but instead that increases in rates of new-firm entry into the market, spurred by the prospect of supranormal returns, drive down prices. Both prices and heightened rates of innovation due to increased numbers of competitors together stimulate market takeoff.

FIRM LEVEL

It is widely understood that large established companies are capable of creating and commercializing new products that offer incremental benefits to the market, but that they struggle in their attempts to develop new-to-the-world, RIs that confer whole new business and rejuvenation opportunities (Burgelman, 1983; Christensen, 1997; Dougherty, 1995; Fast, 1979; Leifer *et al.*, 2000). Empirical evidence across a variety of industries is mounting, however, linking RI to superior economic performance (Cho and Pucik, 2005; Sorescu and Spanjol, 2008), so the need to overcome these challenges and develop capabilities for radical and other forms of major innovation appears to be a critical issue for established firms and continues to command scholarly attention.

While RI is an important path to generative growth that established organizations might employ, evidence suggests that forces within such organizations can impede its success (Dougherty, 1995; Leifer *et al.*, 2000). Organizations rely on established routines (Nelson

and Winter, 1982): procedures that promote efficiency and automation over creativity and flexibility. They grow by gaining efficiencies of scale and scope in core competency areas that ultimately turn into core rigidities or core incompetencies (Dougherty, 1995). Reliance on established routines, which is key to the established firm's ability to earn profits in known, well-established markets, reduces an organization's ability to cope with uncertainty in any manner other than to ignore it or elect not to engage in opportunities that introduce it. This precludes most opportunities that could result in RI, since each breakthrough, by definition, is unique, and situation-specific knowledge must necessarily be developed. For RIs, relying on past experience is not necessarily an aid to current opportunity. Technical uncertainties abound for most breakthroughs, but so do high levels of uncertainty and discontinuity in markets, resources, and organizational changes required to successfully commercialize them (Chandy and Tellis, 1998; Leifer *et al.*, 2000; Rice *et al.*, 2008).

Empirical evidence points to the fact that new venture groups or other incubator-type models in large organizations do not last long enough for their portfolios of innovations or the development of new innovation competencies to have an impact on the organization (Fast, 1979; O'Connor and Maslyn, 2002). Other scholars argue that organizations can develop appropriate management systems for RI but simply have not (Hill and Rothaermel, 2003; Leifer *et al.*, 2000; O'Connor *et al.*, 2008).

Sustained commitment to building an RI capability is a perennial challenge for firms, since the twin objectives of exploring (developing new lines of business through managing for breakthroughs) and exploiting compete for resources, and involve drastically different management systems. While ambidexterity is perceived to be a virtue (Tushman), the processes associated with exploitation appear to have the upper hand in managerial decision making, primarily because the connection of managerial decision to observed consequence is so much clearer than in the case of exploration activities (March, 1991). Thus, firms invest in improving exploitation practices at the expense of ignoring the development of good practice for exploration,

or new business creation. Yet, profits gained through innovative activities are termed *Schumpeterian* or *entrepreneurial rents* because they are the rewards to firms who are prepared to act in the face of ex ante uncertainty (McGrath and Nerkar, 2004). The motivation to engage in potential RIs is thus always present within firms, for financial as well as employee motivational reasons.

FROM PEOPLE TO PROCESSES TO MANAGEMENT SYSTEMS

Reliance on individuals. The term *intrapreneuring* was popularized in the mid 1980s (Pinchot, 1985) to reflect the view that major innovation happens when corporate entrepreneurs break rules and create major innovations in spite of corporate resistance (see also ORGANIZING FOR INNOVATION; LEADERSHIP ROLES IN PRODUCT DEVELOPMENT). Once the innovation begins to exhibit success in the marketplace, leadership “retroactively rationalizes” their strategies to incorporate the new initiative (Burgelman, 1983).

Much of the RI literature at the firm level highlights the critical role of the single-minded, impassioned champion (Pinchot, 1985). Recent research, however, is documenting management practices that can help, rather than hinder the management of RI, thus reducing sole reliance on individual intrapreneurs. From a management-theory perspective, the central tenet of dynamic capability theory holds that firms can evolve processes that enable them to develop, change, and rejuvenate themselves. While persistent, skilled, visionary champions are critical to RI, organizations will never maximize their resources and advantages if they do not move from relying on champions to a dynamic capability that includes them as one element of a system.

New processes and structures. A number of organizational experiments, such as corporate venture divisions and external incubators (Xerox Parc), have been invoked as approaches to liberating BIs from the dominant operational excellence orientation in the firm, but these have suffered fairly poor results. New venture divisions, designed to incubate breakthrough or

newstream opportunities until they can compete for resources and attention with mainstream product lines do not, in general, sustain themselves or receive organizational support for more than four or five years, since the fledgling businesses do not achieve large-scale growth quickly enough and managerial patience wears thin (Fast, 1979). The famed Xerox Palo Alto Research Center (PARC), designed as an ongoing skunk-works group to develop such a portfolio, failed as a source of growth and renewal for its mother company, as its innovations were adopted and commercialized by others but rejected by its own sponsoring company. PARC was criticized for being too isolated from the company. Yet, integrating RIs into established businesses is a perennial problem, given the mismatch of potential business models, value propositions, customer usage patterns and market application, and the threat of cannibalization of current offerings that the receiving unit must face (Chandy and Tellis, 1998).

When BIs are governed as a collective, portfolio management processes become important. When BIs occur as a result of an individual champion managing independently, no such portfolio level oversight or thinking comes into play. Consideration of RI portfolios has led to advances in techniques for evaluating such portfolios and has resulted in the development of real options-oriented approaches for evaluating and monitoring the value of an entire portfolio, at the same time, evaluating each project within it (McGrath and Nerkar, 2004).

Management systems for major innovation.

Companies have tried many approaches in recent history, but none of the models has resulted in a sustained successful BI capability. Dependence on either an individual champion or a lack of sophistication regarding appropriate processes and structures may be part of the problem, as evidenced in the literature to date.

A recent perspective that is emerging suggests that, while each of these is a contributing factor, it is the lack of viewing innovation as requiring a management system, in which all of these elements are considered simultaneously and managed in accordance with an innovation objective, that is the fundamental cause of such

poor performance of firms with respect to RI in the long run (O'Connor, 2008; O'Connor *et al.*, 2008). Treating BI as a temporary program, an appendage to the mainstream organization, or a one-off project that the company invests in on an ad hoc basis is risky. It makes innovation vulnerable to the whims and fancies of whoever is in charge, the current financial picture of the firm, or the condition of the capital markets outside the firm. The organization structure for managing a portfolio of RIs, along with appropriate processes, talent recruitment and development, governance and decision making, culture and leadership, and resource systems and metrics, together, comprise a management system for innovation that can help the firm maintain ambidexterity over time.

PROJECT LEVEL

The innovation literature questions the extent to which processes needed to manage an RI mirror those used for traditional new-product development projects, given the high degrees of uncertainty and risk for the former. Sethi and Iqbal (2008) find that the use of Stage-Gate approaches for RIs are counterproductive. A more learning-oriented approach is emerging, that recognizes the need for search in nonlinear pathways, iterative learning, experimental processes, and the development of new capability for each innovation (Bhardwaj, Camillus, and Hounshell, 2006; Cheng and Van de Ven, 1996; Danneels, 2002; Lynn, Morone, and Paulson, 1996; McGrath and MacMillan, 1995; Rice *et al.*, 2008; Sommer and Loch, 2004).

These results are critical for management practice, since search techniques resulting in learning but not in perceived project progress may be viewed by project review boards as failed attempts to achieve milestones. Additional work on project-level oversight is needed to enhance the applicability of the recent research progress on project management techniques to real-world settings. In terms of project-level oversight, Jansen *et al.* (2006) demonstrate that centralized decision making negatively impacts exploratory innovation, implying that senior-level managers may not be appropriately versed regarding how to monitor and engage with BI project teams at this juncture.

FUTURE DIRECTIONS

Rapid gains in understanding of RI, at all levels of analysis, are being made in the academic literature. The industry level of analysis has reached a level of sophistication with regard to the amount and richness of data that is being used to draw conclusions. This reliance on sources of data previously unaccessed has led to the toppling of a fair number of widely held principles that were based on case analyses and conventional wisdom.

At the firm level of analysis, the gains in dynamic capability theory, along with the invocation of the ambidexterity claim, or March's exploration/exploitation theory is leading to rapid developments in the literature that go beyond descriptions of single case studies and exhortations that firms must be ambidextrous to a serious discussion about how that can happen for the world of innovation.

Project-level analyses have additionally moved from the case-descriptive mode to the theoretical and prescriptive, indicating a fairly thorough understanding of the approaches to RI project management and oversight that may be more likely to lead to success, given the level of risk involved.

accelerated product development

Fred Langerak

INTRODUCTION

Accelerated product development is a competitive strategy that seeks to compress the development cycle time of new products. However, there has been little theoretical advancement and empirical model testing regarding when cycle time reduction is appropriate, what factors accelerate product development, and how cycle time reduction affects project outcomes. Since cycle time reduction has become important for managing new-product development, this article defines, organizes, and integrates the literature on accelerated product development. Specifically, we argue that the antecedents that shorten development cycle time are well known, but that there are contradictions in empirical support regarding its outcomes in terms of development expense, product quality, and new-product success. We attribute these inconclusive results to contingency effects, methodological differences, trade-offs in cycle time reduction, the hidden costs of accelerated product development, and differences in new products' windows of market opportunity.

DEFINITION

The popularity of accelerated product development is based on the contention that being fast can facilitate either first-mover or second-mover strategies (Kessler and Chakrabarti, 1996). The faster a firm can develop a new product, the greater the likelihood that it can be the first to market with a new product and reap pioneering advantages (see FIRST-MOVER ADVANTAGE). However, being first to market is not always a guarantee for higher sales levels, particularly when a firm's pioneering advantages are dependent upon the development cycle time of its followers. In other words, a fast imitation strategy on the part of its followers can reduce the firm's first-mover advantages. Moreover, the faster a follower can develop a new product, the more lead time it can put between itself and later movers. The implication is that both pioneers and fast followers should shorten their

development cycle time to build a competitive advantage over later entrants (Chen, Reilly, and Lynn, 2005). Against this background, the literature defines product development cycle time as the time elapsed between the initial development, which includes conception and definition, and commercialization, namely, the introduction of the new product in the marketplace (Griffin, 1997; Kessler and Chakrabarti, 1996). Consistent with the notions of product development time, time to market, innovation time, total time, and lead time, this definition implies that development cycle time can be reduced by increasing the new product's development speed, innovation speed, or speed to market.

LITERATURE REVIEW

The results of consecutive studies of product development best practices by the Product Development and Management Association (PDMA) reveal that product development cycle times have decreased significantly over the past 15–20 years. During the same period, the academic and practitioner-oriented literature on accelerated product development has considerably broadened, and development cycle time has been written about extensively. However, accelerated product development is still one of the least studied subjects in new-product development.

Theoretical grounding. Studies on accelerated product development may be categorized into four streams of research. The first category encompasses grounded-theory approaches and small-sample studies conducted to uncover the drivers of product development cycle time (see Kessler and Chakrabarti, 1996 for a comprehensive review of this literature). The output of these efforts are numerous factors assumed to be associated with development cycle time, including project strategy features (e.g., product complexity, strategic intent, level of innovativeness, and technical difficulty), development process characteristics (e.g., formality, stages, and structure), and organizational characteristics (e.g., team use and assignment level, leadership style, size, and innovation level). Exploratory in nature, this line of research provides a solid

2 accelerated product development

ground upon which theory can be developed (Griffin, 2002).

Antecedents of cycle time reduction. The second category synthesizes these exploratory findings to develop conceptual models and test the hypothesized influence(s) of accelerated product development on project strategy, and process and organizational characteristics on development time (a review of this literature is provided by Griffin (1997)). The empirical results relating to project strategy are unequivocal: newer, more complex, more technically challenging, and more innovative projects are typically associated with longer development cycle times. This suggests that firms striving for shorter development cycle times would need to undertake less complex, less innovative, and less technically demanding projects. While such a strategy may (indeed) reduce cycle time, it clearly carries long-run threats to marketplace success and long-term financial rewards (see INNOVATION METRICS; SUCCESS FACTORS FOR NEW-PRODUCT DEVELOPMENT).

The numerous studies on development process factors as antecedents of cycle time produce less clear results. Clear project (time) goals, partial or complete concurrent processing, acceleration of activities and tasks, detailed process planning, greater investment on both human and financial resources, and, at the fuzzy front end, increased rewards for R&D performance, lead user involvement, and a long-term orientation are associated with decreases in the development cycle time (Calantone and Di Benedetto, 2000). Development processes that use design for manufacturability tenets, new-product screening models, computer-aided design systems, and frequent product testing, and that display high levels of supplier involvement and greater number of customers involved with prototypes are linked to longer lead times (Griffin, 1997). These opposing effects suggest that firms making changes to their development process must closely monitor the impact of their interventions on both development effectiveness and cycle time efficiency, and recognize that a trade-off may be inevitable.

Other studies have identified a number of organizational actions that firms can take to reduce development cycle time, in particular

improving the R&D-marketing-manufacturing interface by establishing cross-functional teams, and simplifying the organizational structure. Increased knowledge levels of team members, greater dedication on part of the project leader, and adoption of a more participatory leadership style have been found to be associated with shorter cycle times (Griffin, 2002). Thus, the empirical results on the antecedents of accelerated product development demonstrate that a considerable number of project strategy, process, and organizational factors are closely associated with product development cycle time. However, an overarching theory to the results across the aforementioned studies is yet to be articulated. The only exception is perhaps Gerwin and Barrowman's (2002) meta-analytic finding that overlap and interaction, tools and formal methods, and team leader influence work toward reducing development cycle time.

Outcomes of accelerated product development.

The third stream of research comprises studies that investigate the outcomes of development cycle time reduction in terms of development costs, product quality, and project success. The studies in this category use multiple methodologies ranging from broad-based surveys and case analyses to simulations, and systematically test the hypothesized effect of cycle time reduction on the three sets of outcomes. The results of these studies do not provide unanimous evidence in favor of accelerated product development. With regard to the effect on development costs, some researchers have found negative correlations, while others have established that shortening development time lowers development costs (see Kessler and Chakrabarti, 1996 for a detailed review). The valence of the relationship between cycle time and product quality is also unclear. One team found that higher product quality is related to decreases in cycle time, while others document its association with increases in cycle time (Griffin, 2002). There is also little empirical support for the notion that reduced product development cycle is a key ingredient to project success. In a review of prior empirical studies, Chen, Reilly, and Lynn (2005) conclude that the literature has produced inconsistent, even conflicting, results on the relationship between development cycle time and project success.

In sum, while many view the realization of shorter cycle times as an important means to reducing development costs, improving quality, and attaining better project success, there seems little empirical support that substantiates this contention.

Contingency effects. The fourth category of research reflects on these divergent empirical results via its employment of (mainly) the survey methodology to examine the moderating effects of contextual factors, such as uncertainty, product innovativeness, new-product strategy, team improvisation, and customer participation. Mixed results have been documented in relation to market uncertainty, with some studies suggesting a weaker association between speed to market and project success, and others revealing higher correlations between these variables under conditions of uncertainty. There is, however, little dispute surrounding the finding that technological uncertainty has little, if any, effect on the speed-success relationship. With regard to project innovativeness, several studies suggest that innovativeness weakens the effect of product development cycle time on project success (Ali, 2000). Concerning strategy, findings imply that pioneers and fast followers should not use the same acceleration approaches, as the impact of the majority of these approaches on cycle time and profitability is moderated by the new-product strategy of the firm (Langerak and Hultink, 2005). Moreover, reduction of development cycle time is generally considered more essential to fast followers than for pioneers since it can help reduce the pioneer's lead time over later entrants. As far as improvisation is concerned, findings show that team improvisation in the context of a structured development process increases the likelihood of reduced cycle time and increased new-product profitability. Finally, research shows that customer participation as an information resource has a positive effect on speed to market when downstream customer connectivity is high, but no significant effect when it is low. In addition, customer participation as codeveloper undermines new-product speed to market when process interdependence is high. When interdependence is low, the effect of customer

participation as codeveloper on speed to market is significant and positive.

DIFFERENCES RELATED TO MEASUREMENT METHODS

The conflicting results of research on accelerated product development are commonly attributed to methodological differences in measurement approach and unit of analysis, and the relative importance of development cycle time reduction for new-product success (Chen, Reilly, and Lynn, 2005).

Measures. One source of inconsistency across studies stems from different assertions regarding the appropriate starting and end points of the product development cycle, and the consequent differences in cycle time assessment. Moreover, many studies suffer from a lack of rigor in data presentation, rendering the comparison of measures problematic in the face of different time frames (Griffin, 1997). Other discrepancies arise due to the variability in the conceptualization of cycle time and the diversity of approaches employed for its measurement. One approach, for instance, uses the actual elapsed time between the spark and the launch of the new product in the market. Alternatively, relative product development cycle time is based on a comparison of the elapsed time with planned or expected time to facilitate comparisons across development projects of firms from different industries. Cycle time is also measured as a comparison of the elapsed time of a particular project against schedule, or with the elapsed time of other projects within the firm or those of competitors.

Unit of analysis. A related problem involves the unit of analysis at which accelerated product development is studied: the organization or the project (Kessler and Chakrabarti, 1996). Some variables (e.g., project leader influence, cross-functional teams) that are necessarily measured at the project level may be neither operational nor meaningful at the organizational level. In addition, studies at the organizational level tend to collapse the results of a firm's development projects, obscuring not only the particular characteristics of individual projects, but also the effect of development cycle time on a specific project's success. Analysis at the

4 accelerated product development

project level enables a study to capture unique situational attributes that influence the project processes and outcomes. Not surprisingly, there is a growing consensus in the academic literature that theory and research on accelerated product development should focus at the project level.

Impact. With regard to the conflicting outcomes it has also been argued that the importance of cycle time reduction for new-product success is small compared with other key drivers, and that its effect is thus swamped in the noise. This explanation is certainly a possibility because the financial benefits of accelerated product development, while potentially significant, are likely to be small in comparison with the financial leverage exerted by other factors such as product advantage, the ability of the product to meet customer needs, predevelopment task proficiency, dedicated R&D resources, technological proficiency, and launch proficiency (Henard and Szymanski, 2001). Another line of reasoning is that certain development time thresholds must be exceeded in the concept generation and volume production stages of the development process for any significant effect of cycle time reduction on project success to be detected.

TRADE-OFFS IN ACCELERATED PRODUCT DEVELOPMENT

Another explanation for the conflicting outcomes of accelerated product development comes from a theory of trade-offs in new-product development projects (Swink, Talluri, and Pandejpong, 2006). According to this theory, certain practices used to shorten development cycle may be counterproductive in other ways. Most studies on accelerated product development, however, have limited their examination to the extent of development cycle time reduction without any reference to its possible implications on development expense, product performance quality, and/or product profitability. At the same time, these studies suggest that trade-offs may exist between pairs of these development outcomes, requiring that the objectives in accelerated product development should be balanced.

Several studies suggest that the relationship between cycle time and development expenses is

U-shaped (Bayus, 1997; Langerak, Hultink, and Griffin, 2008). Reducing development cycle time to below the minimum of the U-shaped curve increases the pressure on financial resources due to higher coordination costs, additional expenses for overtime work, correcting for errors that may have resulted from skipping process steps, and an intensified need for support resources, particularly, among teams involved in accelerated projects. Allowing the new product's cycle time to go above the function's minimum has the similar effect of increasing costs due to decay of know-how, loss of motivation, and the emergence of additional setup costs. An overly loose schedule thus wastes resources because of dissipated efforts and lapses of attention (Langerak, Hultink, and Griffin, 2008).

Researchers have also studied trade-offs among other pairs of development objectives. Calantone and Di Benedetto (2000), for example, provide an analytical model of the link between development cycle time and product performance. They conclude that keeping a new product in development is preferable to the accelerating time to market if the base product performance is low. The trade-off between development cycle time and product performance has also been investigated empirically, and yielded mixed findings (Swink, Talluri, and Pandejpong, 2006). Likewise, support for a development expense-product performance trade-off has been mixed. Finally, timing and performance decisions have been reported to depend on the asymmetries in competitors' market estimates and development efficiencies (Bayus, Jain, and Rao, 1997).

In summary, the literature identifies many mixed findings on the hypothesized trade-offs between development project objectives, suggesting the need for a broader theory that explains the nature of the trade-offs, and empirical research that addresses multiple project outcomes and relevant boundary conditions (e.g., maximum development expenses or minimum product performance) in a more holistic manner.

ACCELERATION TECHNIQUES

Within the literature on accelerated product development, a notable number of studies have

sought to identify those acceleration techniques that new-product teams actually use to reduce development time. The earliest framework for the use of techniques was developed by Millson, Raj, and Wilemon (1992) who suggested a hierarchy of acceleration approaches. Each approach is composed of similar techniques aimed at simplifying development operations, eliminating unnecessary development activities, paralleling development activities, eliminating delays in the process, and speeding up development operations. They concluded that a firm's time to develop new products can be significantly reduced to the extent these five acceleration approaches are employed in a thoughtful manner. In similar vein, Langerak, Peelen, and Nijssen (1999) specified a set of 50 individual acceleration techniques that development teams can adopt to achieve cycle time reduction. They formed nine approaches to shorten development time by clustering similar techniques.

In a follow-up study, Langerak and Hultink (2005) investigated the effect of each cluster on development cycle time and new-product profitability. The results revealed five out of nine acceleration approaches (i.e., supplier involvement, lead user involvement, speeding up activities and tasks, training and rewarding of employees, and simplifying organizational structure) to be associated with reduced development cycle times. Implementing support systems and techniques and stimulating interfunctional coordination, on the other hand, were found to be linked to increased cycle times. The results further showed that three approaches (i.e., lead user involvement, training and rewarding of employees, and an emphasis on the customer) improve new-product profitability, while three other approaches (i.e., speeding up activities and tasks, reduction of parts and components, and implementation of support systems and techniques) decrease new-product profitability. A closer inspection of these results reveals that the use of only two approaches (i.e., lead user involvement and training and rewarding of employees) simultaneously reduces development time and improve new-product profitability. The adoption of one approach (i.e., speeding up activities and tasks) reduces development time to the detriment of profitability,

an observation consistent with theories that suggest a trade-off between development time and new-product profitability.

RISKS IN CYCLE TIME REDUCTION

Crawford (1992) argues that the existence of trade-offs also imply risks associated with the practices aimed at cycle time reduction. A firm may focus on incremental new products at the expense of true breakthroughs and necessary information search steps may be sacrificed. Launching a new product too early, particularly when the product is qualitatively not ready for the market, is a notable risk. An overly tight time schedule also raises the probability of mistakes being made because it pushes the development project beyond the limits of R&D, engineering, and marketing capabilities. There are also people costs involved in managing cross-functional teams; time budget cuts can constrain the amount of innovation achieved; and a speeded-up team can consume an inordinate share of firm resources. Furthermore, team members in a functionally organized firm may be under work stress not only because of divided loyalties between their functional area and the development team, but also because of the increase in their workload as a consequence of being a part of the development team. In light of these risks, some researchers have suggested that timely development of a new product, given a new product's window of opportunity, is more important than achieving the shortest development cycle time possible.

Market window of opportunity. The majority of existing work has not taken the new product's window of opportunity into account while investigating the effect of cycle time reduction on the success of the product. The concept of window of opportunity is, however, important because the sales of a new product that is launched ahead or behind its time will suffer (Calantone and Di Benedetto, 2000). Research suggests that by rushing a new product to market, a firm risks facing a strategic window yet to open, because in the early stages of the new product's life cycle there is likely to exist incompatibility with customers' existing way of doing business, and a greater perceived risk of adoption. Moreover, cycle time reduction may negatively affect

product performance. Conversely, by taking too long to develop a new product, a firm may miss the window of opportunity. Customers already exposed to existing products are not likely to postpone their purchase decision, especially if competitors have already introduced similar new products. Contemporary research even suggests that the firm's ability to get the market-entry timing right, in view of the market window, is more important for new-product profitability than reduced cycle time, although it should be kept in mind that market-entry timing is contingent upon the completion of the new product's development cycle (Langerak, Hultink, and Griffin, 2008).

CONCLUSION

This discussion of accelerated product development provides scholars with a theoretical foundation for rigorous, empirical research. The challenge is, of course, to build on prior studies to investigate and further clarify some of the issues without losing sight of the complex relationships pertaining to the context, antecedents, and outcomes of development cycle time reduction. In doing so, researchers should consider the need for consistency in the unit of analysis and the measurement of development cycle time. From a practitioner's perspective, this discussion is useful in its clarification of the merits of cycle time reduction and the situations in which it is most appropriate, delineation of the ways in which interventions can be applied, explanation of the risks, trade-offs and pitfalls of development time reduction, and exploration of the competitive implications of accelerated product development.

product life cycle

Peter N. Golder and Gerard J. Tellis

INTRODUCTION

The product life cycle (PLC) is a central, enduring framework in marketing and many other fields including economics, management, production, logistics, engineering, political science, and travel and tourism. In this article, we present its theoretical underpinnings, metrics for its key turning points, and general findings of its characteristics.

The PLC describes the sales history of a new product in terms of four stages: introduction, growth, maturity, and decline. The concept was developed initially in the early 1950s, triggering extensive empirical research in the 1960s (Rink and Swan, 1979). Most of this research sought to validate the PLC in one or more groups of products. Yet, this research did not yield generalizations about the PLC, and the primary researchers differed in their conclusions about the usefulness of the PLC (Polli and Cook, 1969; Buzzell, 1969). Three primary factors underlie these different conclusions:

- *Level of aggregation:* The PLC can apply to various levels of product aggregation: the product class, form, or brand. Different studies tested the PLC at different levels. This made comparisons across studies difficult, especially if different patterns hold at different levels of aggregation. The PLC concept may be especially inappropriate for brand-level analysis. We agree with Lambkin and Day (1989) that the product category level is most appropriate for the PLC concept.
- *Research focus:* Past studies focused on products or brands in substantially different groups of products, such as food, personal care, consumer durables, and industrial products. The PLC is more likely to have distinct patterns *within* such groups of products, particularly, new consumer durables, which are significant improvements over existing products.
