- *Nature of the concept:* As with other concepts in the social sciences, the PLC is likely to be probabilistic rather than deterministic. Past empirical studies tended to highlight unique differences in life cycles as deviations from a deterministic pattern, rather than emphasizing probabilistic commonalities.

DEFINITIONS

We define a *product category* as a group of products without close substitutes that, from the consumer's viewpoint, fulfill a distinct need. For example, refrigerators, CD players, and camcorders are product categories. Each of these categories may encompass multiple brands that are close substitutes of each other. A product form is a subcategory of products that satisfy particular consumer needs within the product category. Product form is a level of aggregation between product category and brand. For example, VHS, VHS-C, 8mm, and mini-DVD are different forms within the product category of camcorders. Product forms typically meet the needs of a distinct segment of consumers in the market for camcorders.

We define the four standard stages of the PLC, as follows: (i) *introduction* is the period from a new product's commercialization until its takeoff; (ii) *growth* is the period from a new product's takeoff until its slowdown in sales; (iii) *maturity* is the period from a product's slowdown until sales begin a steady decline because of the emergence of a new product that satisfies essentially the same need; and (iv) *decline* is the period of steadily decreasing sales until a product's demise due to complete substitution by a superior new product.

In addition, we define three key events that mark the beginning and end of the first two stages: (i) *commercialization* is the point at which a new product category is first sold to consumers; (ii) *takeoff* is the point of transition from the introduction to the growth stage of the PLC. It is the first dramatic and sustained increase in product category sales (see TAKEOFF). (iii) *Slowdown* is the point of

2 product life cycle

transition from the growth stage to the maturity stage of the PLC. The slowdown signals the beginning of a period of level, slowly increasing, or temporarily decreasing product category sales.

Measurement of commercialization is fairly straightforward, although there are often different starting years for businesses and individual customers (Golder and Tellis, 1997; Golder, Shacham, and Mitra, 2009). A common metric for measuring takeoff is the first year in which a product's growth rate relative to its previous year's unit sales is higher than a predetermined threshold (Golder and Tellis, 1997). Other studies measure growth relative to market penetration, which is more appropriate when investigating commonalities across countries (Chandrasekaran and Tellis, 2008; Tellis, Stremersch, and Yin, 2003). A measure of slowdown is the first year of two consecutive years after takeoff, in which sales are lower than the highest previous sales. The measures of takeoff and slowdown match a visual inspection of the sales curves in nearly all product categories.

AN INTEGRATED THEORY OF THE PRODUCT LIFE CYCLE

Our integrated theory draws on research in marketing, diffusion, behavioral economics, and technology management. The PLC is primarily the confluence of two general underlying forces: consumer demand and producer supply. These two forces work simultaneously and interactively to give the life cycle its shape.

Consumer demand. Consumer demand is the primary force driving the PLC. In particular, three important components of demand play a role in shaping the PLC: diffusion, affordability, and informational cascades.

Diffusion. Diffusion explains how the knowledge of a new product evolves through a population (*see also* DIFFUSION OF INNOVATION). The idea has roots in the work of Everett Rogers, and has been extensively documented in marketing (Lambkin and Day, 1989; Mahajan, Muller, and Bass, 1990; Rink and Swan, 1979; Rogers, 2003). This stream of research suggests

that knowledge of innovations and their benefits diffuse in a population, from segment to segment, and from user to user within segments, by media reports, word of mouth, observation, and imitation. The reason it diffuses this way is because these segments differ in their propensity to innovate. In particular, certain factors, such as age, education, mobility, and social desirability, influence this propensity to adopt innovations. As a result of these differences, various consumer segments are likely to adopt innovations sequentially. A great body of research reports that, typically, the segments that adopt the innovation very early or very late are small, while those that adopt it in between these groups are large. As a result, a plot of adoptions against time gives the typical normal or bell-shaped PLC curve. By adding repeat sales to sales from adoptions, one gets the total sales curve. If adoptions typically follow a normal distribution, then the early part of the life cycle of a new product will have an S-shape. The length and shape of the maturity stage of the PLC depends increasingly on replacement purchases. For fad and fashion products, this stage may not last long. For durables, this stage can be very long.

Affordability. The actual purchase of a product occurs when consumers find that the benefits of the product are equal to or higher than the price of the product. Thus, affordability plays an important role in takeoff and growth. Typically, information about the new product diffuses much more rapidly through a population than does the purchase of the product itself. Therefore, far more people want new products than are willing to buy them at their current prices. Because of technological improvements and manufacturing efficiencies, new products improve rapidly in benefits to consumers, while their prices come down. The prices of new products decrease substantially during the introduction stage (Golder and Tellis, 1997). As prices continue to decline during the growth stage, affordability is enhanced and sales push higher.

Informational cascades. Informational cascades describe how people converge on adopting a new product (or behavior) with

increasing momentum and declining individual evaluation of the merits of the new product, because of their tendency to derive information from the behavior of prior adopters (Bikhchandani, Hirshleifer, and Welch, 1992). The essence of informational cascades is that even though individuals make decisions on the basis of their own private information, their decisions are also influenced by other people's decisions. As people adopt a new product on the basis of its merits, their adoption provides a signal to nonadopters. Some of these nonadopters go on to adopt the new product, at least partially influenced by the behavior of the previous adopters. As the number of adopters increases, they provide an increasingly strong signal to nonadopters, who then adopt in increasing numbers. Once information derived from the decisions of others begins to outweigh an individual's private valuation, the process begins to increase in momentum or cascade toward conformance in the behavior of more and more buyers.

At this point, new adopters reveal no additional private information to the market. Thus, the mass conformance or cascade to a particular behavior is based on the initial decisions of a small number of adopters, rather than the cumulative decisions of all adopters. This feature makes a cascade quite fragile. It is easily triggered or reversed by new information that affects the decisions of a small number of people. Therefore, cascades can depress pre-takeoff sales, sharpen the takeoff of new products, exaggerate product growth, and reverse sales growth when maturity first sets in. We elaborate on these points. Since most individuals do not purchase a new product during the introduction stage, most consumers use this information to decide likewise. This decision may occur even when, for some individuals, private information alone would have led to purchasing the new product. As a result, early sales of a new product could be depressed or time to takeoff could be longer than seems justified by the potential utility of the new product (Golder and Tellis, 1997; Tellis, Stremersch, and Yin, 2003).

On the other hand, once a sizable segment of consumers adopts the new product, other consumers use this information to decide to purchase the new product as well. These

purchases occur even when their own private valuation could have meant they should not purchase the new product. In such a positive cascade, more consumers buy than might be expected on a strict cost-benefit analysis. This cascade of consumers to adopt a new product is likely to end somewhere. Potential triggers include a decline in the growth rate of the new product's benefits, the announcement of a rival technology, or a change in the economic environment, such as an increase in interest rates or the onset of a recession. Any of these may be small shocks to the system. However, in the presence of a cascade in favor of the new product, any of them might be enough to reverse the sales trend. Some informed consumers might decide to wait before purchasing the new product. Other consumers may have already bought the product before their private valuations justified such a purchase. Once some consumers delay their purchases and other consumers become aware of these decisions, a negative cascade begins. As a result, the slowdown in market sales might not be a gradual flattening of the sales curve, but a drop in sales at the onset of maturity.

Producer supply. Producer supply is the second major force driving the PLC. In particular, two important components of supply play a role in shaping the PLC: technology evolution and market competition.

Technology evolution. While demand-based forces are widely recognized in marketing, supply-based forces, such as technology, are considered less frequently. However, technology-based life cycles have a strong theoretical foundation and are particularly relevant to consumer durables. Therefore, some progress on PLCs may be possible by considering these supply-side factors (Lambkin and Day, 1989). The role of technology in the PLC can be succinctly described by the phenomenon of the S-curves of technological change (Chandy and Tellis, 2000; Foster, 1986). Product improvements are commonly driven by technological evolution that proceeds along a series of successive S-curves (*see* TECHNOLOGY S-CURVE). The S-curve emerges because an

Figure 1 Average sales history.

existing technology improves slowly in benefits to consumers when first introduced, then rapidly as research on the technology advances, and finally slowly again, as research reaches the limits of that technology. The pattern of S-curves plays a critical role in the PLC. However, regularity in S-curves is itself questionable while the life cycle of the product does not mimic the S-curve of its underlying technology (Sood and Tellis, 2005). For example, the takeoff of the new product occurs when the new technology surpasses the old technology and not at the takeoff of the new technology.

Market competition. The final force driving the PLC has been studied during the introduction and early growth stages. One of the main determinants of sales takeoff is found to be the number of competitors in the market. Interestingly, there is a takeoff in the number of competitors that tends to precede the takeoff in sales. More competitors are likely to drive improvements in quality (both actual and perceived) and make a contribution to sales gains that may supersede even the positive impact of declining prices (Agarwal and Bayus, 2002).

EMPIRICAL REGULARITIES IN THE PLC OF CONSUMER DURABLES

We now report observed regularities in the PLC based on a sample of 30 new consumer durables consisting of household appliances and consumer electronics introduced between 1900 and 1990 (Golder and Tellis, 2004).

We use sales data in each category to construct a “typical” or average PLC for all categories and for the subset of categories introduced after World War II (see Figure 1). The three key events enable us to demarcate the stages of new-product sales and present descriptive results on growth rates and unit sales. Our analysis of sales after the slowdown leads us to divide the maturity stage into two substages, early maturity and late maturity. Early maturity begins with the year of the sales slowdown and continues until sales grow to the previous local peak. Late maturity begins with the first year that sales are higher than the local peak and continues until a product’s sales begin to fall steadily during the decline stage. Only a few of our categories have reached the decline stage, so we do not report findings for this stage.

Figure 1 confirms the importance of properly identifying takeoff and slowdown because the average life cycle changes so distinctively at these points. In particular, after slowdown, sales take several years to surpass the previous local peak (Goldenberg, Libai, and Muller, 2002).

Characterization of stages and events. Table 1 contains the growth rates during the stages and at the key events of the PLC. Growth rates vary dramatically over the PLC. While growth is high during the introduction, the base is relatively small; so these percentages do not represent substantial increases in unit

Table 1 Growth rate (%).

^aNine categories with sales data for three years before takeoff and base sales of at least 15 000 units.

^bMinimum sales after slowdown relative to sales at local peak.

sales. However, at takeoff, the market for these new products changes dramatically with an average sales increase of over 400%. During the growth stage, sales increase at 45% per year, on average. In addition, the higher base of sales after takeoff means that the increases in unit sales are quite substantial (*see also* GROWTH STRATEGIES).

At slowdown, the sustained period of rapid growth suddenly reverses into a 15% decline. Our theoretical discussion of informational cascades helps to shed some insight into the sales reversal at slowdown. After slowdown, sales tend to decline for a few years, reaching a minimum of 25% below the local sales peak prior to slowdown. During late maturity, sales surpass the previous local peak in sales but tend to grow at a much slower rate (3.7%). Sales growth during maturity seems to reflect increases in the total economy (*see also* MANAGING MATURE PRODUCTS).

Table 2 contains the mean unit sales at three key events: commercialization, takeoff, and slowdown. These averages provide benchmarks for judging the success of today's new products (*see also* NEW-PRODUCT FORECASTING).

Table 3 presents results on market penetration at takeoff and slowdown. Penetration at takeoff varies significantly between older and newer categories, but average penetration at slowdown does not vary.

Information about relative prices is presented in Table 4. Larger price reductions in more recent periods may be because of stronger experience effects associated with larger national and international markets, more electronic components, and managers exploiting these experience effects more often.

Results on the stage durations are presented in Table 5. The duration of the growth stage has not been shortening over time. However, the durations of introduction and early maturity

statistics for 30 new consumer durables lends additional support to this view. Moreover, these statistics provide benchmarks for managers and researchers of today's new products. On the basis of our theory and results, managers would need to anticipate an extended pre-takeoff period, a sharp takeoff, and then a slowdown in sales after about eight years of rapid growth. By

portfolio management

Scott J. Edgett

INTRODUCTION

Product innovation is vital to the modern corporation. Driven by rapidly advancing technologies, globalization of markets, and increasing competition at home and abroad, effective product innovation is critical to successful corporate performance.

A vital question in product innovation is: How should corporations effectively allocate their research and development (R&D) and new-product resources? Portfolio management is all about maximizing resources to achieve strategic product innovation objectives. Executives who optimize their R&D investments by defining the right product innovation strategy for the firm, by selecting winning new-product projects, and by achieving the ideal balance of projects, will come out ahead in the long run. These executives practice effective portfolio management for product innovation.

PORTFOLIO MANAGEMENT DEFINED

The portfolio decision-making process encompasses, or overlaps, a number of decision-making processes within the business. Portfolio decisions include periodic and holistic reviews of the total portfolio of all projects, making Go/Kill decisions on an ongoing basis, and implementing the product innovation strategy for the business. This includes strategic resource allocation decisions within selected arenas.

Portfolio management is operationalized on both the strategic and tactical levels. The portfolio decision process is characterized by uncertain and changing information, dynamic opportunities, multiple goals and strategic considerations, interdependence among projects, and multiple decision makers (Cooper, Edgett, and Kleinschmidt, 1997a, 2002a, 2002b). Portfolio prioritization is a dynamic decision process. A business's list of active new-product (and development) projects is constantly updated and revised. In this process, new projects are evaluated, selected, and prioritized. Existing projects may be accelerated,

killed, or de-prioritized, with resources reallocated to active projects as required (Figure 1).

CHALLENGES TO GOOD PORTFOLIO MANAGEMENT PRACTICES

There are four unique facets to good portfolio management that make it one of the more challenging decision-making functions in an organization:

- Portfolio management for product innovation deals with future events and opportunities; thus, much of the information required to make project selection decisions is at best uncertain, and at worst unreliable.
- The decision environment is dynamic: The status and prospects for projects in the portfolio are ever changing, as markets shift and new information becomes available.
- Projects in the portfolio are at different stages of completion, yet all projects compete against each other for resources. Therefore, comparisons must be made between projects based on information that differs in quality and quantity.
- Finally, resources available to be allocated across projects are limited: A decision to fund one project may mean that resources must be taken away from another; and resource transfers between projects are usually not totally seamless.

THREE MAIN GOALS IN PORTFOLIO MANAGEMENT

How should one go about setting up a portfolio management system? There are three main goals that an effective portfolio management system should achieve:

- *Strategic alignment.* The main goal is to ensure that, regardless of all other considerations, the final portfolio of projects truly reflects the company's innovation strategy: that all projects are "on strategy," support the strategy, and/or are critical components of the strategy; and, that the breakdown of spending across projects, areas, and markets, is directly tied to the business strategy.

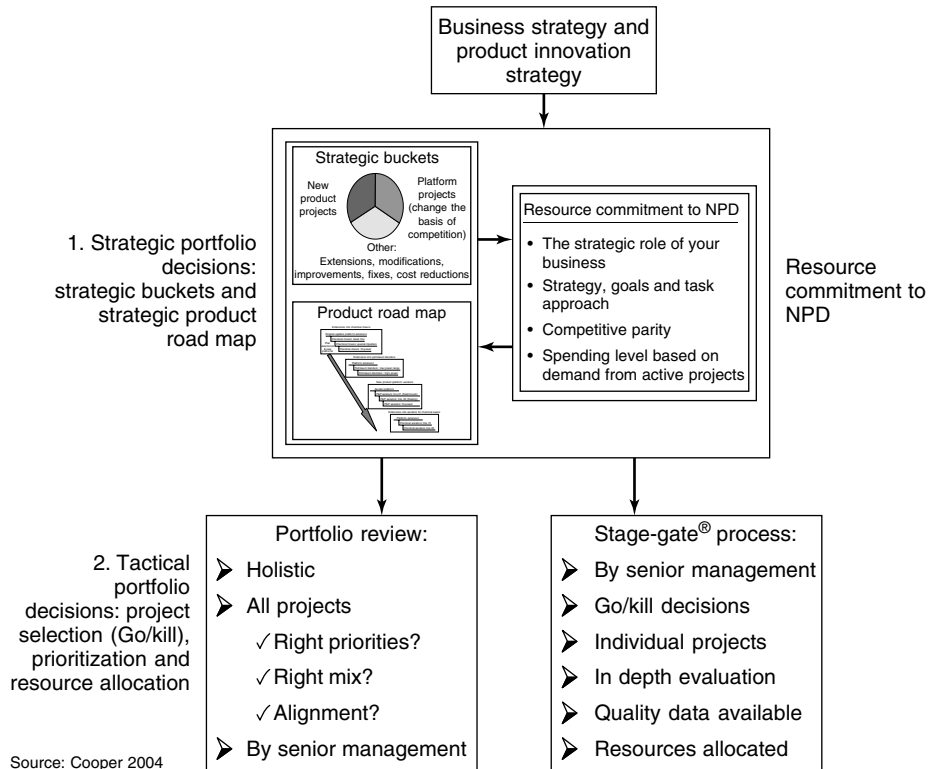

Figure 1 The portfolio management system and its elements (reproduced from Cooper, R.G. (2004) Product Leadership: Pathways to Profitable Innovation, 2nd Edition. Cambridge, MA: Basic Books. © The Perseus Book Group).

- *Maximize the value of the portfolio.* Here the goal is to allocate resources to maximize value for a given spending level. In other words, projects are selected to maximize the sum of the commercial value of all active projects in the pipeline. This can be measured by a business objective such as net present value (NPV), return on investment (ROI), or likelihood of success.
- *The right balance of projects.* The goal is to achieve the desired balance of projects in terms of a number of parameters to ensure strategic alignment. For example, a company might seek the right balance in terms of long-term projects versus short-term ones; or high-risk versus lower-risk; or across various markets, technologies, product categories, and project types (e.g., new products, improvements, cost reductions, maintenance

and fixes, and fundamental research) (see also INNOVATION TYPOLOGIES).

To achieve these three key goals, portfolio management is separated into two distinct but related levels: strategic and tactical. This permits different decisions to be addressed at their appropriate degree of intensity within the organization (e.g., whether the issue is of a strategic nature or of a resource allocation nature).

STRATEGIC PORTFOLIO MANAGEMENT

Strategic portfolio decisions answer the following questions:

- Directionally, where should the business deploy its product innovation resources (people and funds)?

- How should resources be split across project types, markets, technologies, or product categories?
- On what major initiatives or new platforms should the business concentrate its resources?

Typical aids to answer these questions are (i) creating a strategic product roadmap; (ii) defining strategic buckets (or arenas); and (iii) determining the total resource commitment necessary to achieve innovation goals (money and people).

Creating the strategic product road map. The development of a product road map flows logically from the product innovation strategy. Delineating the major initiatives required for the road map includes the following:

- *Strategic assessment.* Sometimes the mere specification of a strategic arena as a top priority leads logically to a list of products and projects that are necessary to be successful in that arena. For example, a major food-products company identified “healthy snack” as a priority strategic arena (the company already sold a few products in this sector, but was a minor player). As soon as this happened, the products required to be successful in this market segment became self-evident. As a result, the development programs needed to generate these products fell into a logical sequence in a product road map.
- *Portfolio review of existing products.* Here, a hard look at the business’s current product offerings is undertaken, and decisions are made as to which products should be cut, continued, or replaced. Forecasts of products’ life cycles often reveal the need and timing for replacement products and, even new platforms. Additionally, gaps in the product lines are identified (*see* PRODUCT-LINE STRATEGIES). Then, place marks are inserted in the product road map for these development actions. This exercise is undertaken periodically to keep the product line fresh and complete.
- *Competitive analysis.* Where are the business’s current and future products and

product lines relative to competitors (*see* COMPETITIVE ADVANTAGE); this is evaluated by assessing competitors’ current and probable future offerings, where they have advantages and where the gaps are. This exercise often points to the need for new products.

- *Technology trends assessment.* Here one forecasts the types and timing of new technologies and the new platform developments that will be required as a result (*see* PRODUCT PLATFORMS). For example, the advent of each new cell-phone technology signals a host of development projects within cell-phone manufacturing firms, as well as within service providers.
- *Market trends assessment.* This is also a forecasting exercise that looks at major market trends and shifts (*see also* NEW-PRODUCT FORECASTING). In this exercise, one is often able to pinpoint specific initiatives that must be undertaken. An example is shifting purchasing patterns in favor of more environmentally friendly products.

Strategic buckets. When translating the business’s strategy into strategic portfolio decisions, a major challenge is determining spending breakdown or deployment; that is, where does senior management need to spend its resources when it comes to product innovation – on what types of projects, and in what product, market or technology areas? And how much do they need to spend in each area? The strategic-buckets model operates from the simple principle that implementing strategy equates to spending money on specific projects. Thus, operationalizing strategy really means “setting spending targets.” Strategic buckets can be used with, or instead of, the product road map.

This method begins with the business’s strategy, and requires senior management to make choices that enable the creation of “envelopes of resources” or “buckets.” Existing projects are categorized into buckets; then, actual spending is reviewed for consistency with desired spending for each bucket. Finally, projects are prioritized within buckets to arrive at the ultimate portfolio of projects – one that mirrors management’s strategy for the company.

4 portfolio management

Some common ways to categorize buckets are

- *Along strategic goals.* Management splits resources across the specified strategic goals. For example, what percentage will be spent on defending the base? On diversifying? On extending the base?
- *Across arenas.* This means defining the spending splits across strategic arenas defined in the business strategy. Arenas are generally product, market, or technology areas where the business wishes to focus its new-product efforts.
- *Along product lines.* Resources are divided among product lines. A plot of product-line locations on the product life-cycle curve is used to help determine this split.
- *Along types of projects.* Buckets may be allocated according to the types of projects.
- *By technologies or technology platforms.* Spending splits can be made across technology types (e.g., base, key, pacing, and embryonic technologies), or across specific technology platforms.
- *By familiarity matrix.* What should be the split of resources to different types of markets and to different technology types in terms of their familiarity to the business? Some companies use the popular “familiarity matrix” – technology newness versus market newness – to help split resources.
- *By geography.* What proportion of resources should be spent on projects aimed largely at North America? At Latin America? At Europe? At Asia-Pacific? Or globally?
- *By stage of development.* Some businesses distinguish between early stage projects and projects in development and beyond. Two buckets are created, one for development projects, the other for early stage projects.

The major question with strategic buckets is, “How does a company obtain the optimal split in project types?” Breaking down new products and projects by type helps predict a business’s product innovation performance. For example, too much emphasis on short term, small projects might point to an underachieving business (see Cooper, Edgett, and Kleinschmidt (2005) for additional examples and data). So, ideally a business’s product innovation strategy should be

reflected in the types of product development it undertakes and in where it invests its product innovation resources.

Determining resource commitment. Once the product road maps and strategic buckets have been determined, the third challenge is to determine what the total resource commitment should be to achieve the innovation goals and to properly allocate funds to the various road maps and strategic buckets. The issue here is that there is seldom enough money to fund all of the potential opportunities. So the first decision is how much resources, in aggregate, are needed to properly fund the R&D initiatives to ensure a reasonable probability of success in achieving the strategic goals. The second set of decisions is to properly allocate the funds among the different road maps and arenas. The process for this will usually require several rounds of allocation that result in a series of prioritization choices being made.

TACTICAL PORTFOLIO MANAGEMENT

Tactical portfolio decisions focus on individual project selection, but obviously follow from the strategic decisions. Questions typically addressed are as follows: (i) what specific new-product and development projects should the business undertake? (ii) What priority should these individual projects have? (iii) How should the resources be allocated to each project?

Project selection. Two processes that enable project selection are necessary to make effective tactical decisions. Both work in harmony. They are gates and portfolio reviews.

- *Gates.* Embedded within the idea-to-launch new-product framework are Go/Kill decision points called “gates” (the most commonly used process worldwide is the Stage-Gate® process – see THE STAGE-GATE IDEA TO LAUNCH SYSTEM). Gates allow for in-depth review of individual projects. They provide for Go/Kill, prioritization, and resource allocation decisions. Gates must be part of the portfolio management system.

- *Periodic portfolio review.* Senior management should meet two to four times per year to review the portfolio of all projects. Key issues and questions addressed at these meetings are
 - Are all projects strategically aligned to fit the business' strategy?
 - Does management have the right priorities among projects?
 - Are there some projects on the active list that should be killed or, perhaps, accelerated?
 - Is there the right balance and the right mix of projects?
 - Are there enough resources to undertake all of the projects?
 - Is there sufficiency – if one undertakes these projects, will the business achieve its stated business goals?

Both decision processes – gating and portfolio reviews – are necessary. Note that the gates are project specific and provide a thorough review of each project, in depth and in real time. By contrast, portfolio reviews are holistic: They look at all projects together, but in much less detail. Ideally, if the gates are working, few major decisions or corrective actions are required at the portfolio review. For example, some companies indicate that they only consider projects in aggregate at the portfolio review. However, if the gating process is not working well, then most decisions are made at these quarterly or semiannual portfolio reviews.

TOOLS FOR EFFECTIVE GATE AND PORTFOLIO REVIEWS

Within the gate and portfolio reviews, a number of tools can be used to help achieve portfolio goals – maximize the portfolio's value, achieve the right balance and mix of projects, and ensure strategic alignment – yet not overload the development pipeline.

Maximizing the value of the portfolio. Methods used to maximize value range from financial tools to balanced scorecard models. Each has its strengths and weaknesses (Cooper, Edgett, and Kleinschmidt, 2002a, 2005). The end result of each method is a rank-ordered, or prioritized, list

of “go” and “hold” projects, with the projects at the top of the list scoring highest in terms of achieving the desired objectives. The portfolio's value in terms of that objective is thus maximized. There are many methods available to determine the optimal list of projects. Three of the most common approaches are

- Rank order projects using a financial tool such as NPV.
- Rank order projects using a productivity index based on the NPV. (Note: a productivity index is the ratio of what one is trying to maximize divided by the constraining resource.)
- A balanced scorecard or scoring model approach is based on the premise that a more balanced approach to project selection is desired. A variety of criteria may be used to rate the project. Typical criteria include strategic alignment, product and competitive advantage, market attractiveness, ability to leverage core competencies, technical feasibility, and reward versus risk.

Seeking the right balance of projects. A major portfolio goal is balance (a balanced set of development projects in terms of a number of key parameters). The analogy is that of an investment fund, where the fund manager seeks balance in terms of high-risk versus low-risk stocks; and, balance across industries and geographic areas, to arrive at an optimum investment portfolio. Charts are the most common and effective way to display balance in a product innovation portfolio. These visual representations include portfolio maps or bubble diagrams as well as more traditional pie charts and histograms.

The graphical output can illustrate a number of themes depending on key attributes on which management is trying to achieve balance; for example, risk versus reward, newness to the firm, resource breakdown by project type, markets, products and/or technologies, market timing, and cash flow.

IMPLEMENTING A SYSTEMATIC PORTFOLIO MANAGEMENT PROCESS

Top-performing businesses in product development have implemented systematic portfolio

Source: Cooper, Edgett and Kleinschmidt 2005

Figure 2 Portfolio management practices – impact on performance (reproduced from Cooper, R.G., Edgett, S.J., and Kleinschmidt, E.J. (2005) *Best Practices in Product Development: What Distinguishes Top Performers*, Product Development Institute, at www.prod-dev.com for detailed examples and additional supporting data).

management approaches. They have achieved strategic alignment of projects with their innovation strategies. They have prioritized and ranked their projects effectively for value maximization. And, they achieve the right balance and mix of projects.

Research shows that having a portfolio management approach in place seems to be more important than the details of which tools and metrics one elects to use. In other words, any portfolio system is better than no system at all. Businesses featuring systematic portfolio management processes – regardless of the specific approach – outperform the rest (Cooper, Edgett, and Kleinschmidt, 2005; Cooper and Edgett, 2006, 2008).

Using Figure 2, it is possible to measure how an organization's portfolio management methods compare with the top-performing companies. Score the company on each of the seven variables in Figure 2 on a 0–100 scale, where a score of 100 is highest. The questions on which one scores high or low will provide an excellent starting point for assessing and improving the company's

portfolio performance.

launch strategies

Katrin Talke and Erik Jan Hultink

THE IMPORTANCE OF AN EFFECTIVE LAUNCH STRATEGY

The new-product development (NPD) process is regularly seen as a sequence of stages, which ultimately aims at presenting a new product to its target market and at generating income from sales of the new product (*see also* THE STAGE-GATE IDEA TO LAUNCH SYSTEM). The launch stage encompasses all activities facilitating an efficient diffusion of the new product in the marketplace. These activities have been referred to under the collective terms of *launch strategy*, *market entry*, *new-product launch*, *introduction*, or *market launch* (Hultink *et al.*, 1997).

Decisions made during the launch phase are recognized as important drivers of new-product performance (*see* SUCCESS FACTORS FOR NEW-PRODUCT DEVELOPMENT) (Hultink *et al.*, 1997). The results of a meta-analysis by Henard and Szymanski (2001) underscore that “proficiency of launch” is one of the dominant factors explaining new-product performance. At the same time, new-product launch is often the single most costly step in the NPD process (Hultink *et al.*, 1997). Depending on the product and industry, this can include costs for mass-producing the product, setting up the supply chain, establishing dealer and service networks, training the sales force, and advertising the new product. The launch phase also involves large risks as this stage is often the make-or-break point for a product’s life cycle. Launch managers are confronted with questions such as whether there will be a market apart from the initial innovators and technology enthusiasts, how competitors will react to the new product, and how competition will evolve over time, and whether the product functions will prove stable, and the technology will become the dominant design. Owing not only to the importance of the launch stage but also to the risks and significant commitments of time, money, and resources, formulating an effective launch strategy is a top priority for firms.

THE ANATOMY OF A LAUNCH STRATEGY

A review of the new-product launch research of the last 25 years reveals about two dozen studies that seek to illustrate the nature and performance effects of launch activities. These studies use widely varying conceptualizations and operationalizations of new-product launch activities. While earlier studies do not distinguish between strategic and tactical launch decisions (Yoon and Lilien, 1985), more recent approaches regularly propose these two categories of launch decisions (Hultink *et al.*, 1997; Di Benedetto, 1999; Langerak, Hultink, and Robben, 2004; Hsieh, Tsai, and Hultink, 2006).

While strategic launch decisions are generally made in early stages of the NPD project, tactical launch decisions occur at later stages, mostly after conceptual and physical development of the new product is complete (Hultink *et al.*, 1997). Debruyne *et al.* (2002, p. 161) describe strategic launch decisions as differing from tactical launch decisions in the sense that “they are more important, involve a substantive resource commitment, and are difficult to alter once a trajectory has been selected.”

Most studies in this field define strategic launch decisions as comprising of those decisions that set the parameters within which the new product will compete; that is, they define the objectives of the launch, select the market(s) into which the new product will be introduced, determine the competitive position of the new product, and time the entry (Hultink *et al.*, 1997). Several authors approach the issue of strategic launch decisions by focusing on the difficulties firms face when launching new products. The choice of the market segment(s) to target, the PRODUCT POSITIONING, and the market entry timing are among the most critical and influential decisions.

Tactical launch decisions can still be modified at a later stage in the launch process (Hultink *et al.*, 1997), and are mostly defined along the traditional elements of the marketing mix. Hence, they encompass product, promotion, distribution, and pricing decisions, such as the breadth of product versions launched, the nature and scope of services offered alongside the new product, how and where to distribute

2 launch strategies

and promote the product, and its price (Hultink *et al.*, 1997).

THE IMPACT OF LAUNCH STRATEGIES ON NEW-PRODUCT PERFORMANCE

Most studies dealing with the performance impact of launch strategies start off by illustrating the nature of launch decisions and identify different sets or typologies of associations between strategic and tactical launch decisions (Hultink and Schoormans, 1995; Hultink *et al.*, 1997). In a second step, they analyze the relationships between those sets of launch decisions and new-product performance. Several studies also consider contingencies, like the nature of the new product launched (e.g., product innovativeness, product category; *see* INNOVATION TYPOLOGIES) or the market context (e.g., market and technology dynamics).

A brief review of selected studies shows that Hultink and Schoormans (1995) identify two distinctive launch clusters. The “skimming” cluster is characterized by a technology leadership positioning, a pull strategy, a small product assortment, a company brand name, and a skimming pricing strategy. This launch strategy is recommended for an early entry, while for a late entry, the “penetration” cluster is superior. This group is characterized by a small product assortment, a pull strategy, and a penetration pricing strategy.

Manu and Sriram (1996) identify four launch strategy types. “Product innovators” have the highest sales force expenses, invest most in distribution, have the best image and product quality, and offer the best services, followed by the “process innovators” and “late entrant noninnovators.” While “product innovators” realize the highest market share gains, “former pioneers” are performing best financially and get the highest relative market share (*see also* FIRST-MOVER ADVANTAGE). The results further show that “product innovators” and “process innovators” are mostly found in dynamic markets.

Hultink *et al.* (1997) identify four launch strategy types for industrial products. “Niche innovators” are innovative products launched by pioneers, which serve market niches with a broad product line, a skimming pricing strategy accompanied by high distribution intensity.

“Niche followers” follow with a smaller product line. “Mass marketers” and “would-be me-too” launch strategies adapt new products for the mass market. The most successful launch types are the “niche innovators” followed by the “niche followers” and the “mass marketers.”

When contrasting launch decisions for consumer and industrial products in a later study, Hultink *et al.* (2000) report different key success factors for both groups. Successful consumer goods tend to be brand extensions, more innovative, having a similar price level as the competition and show higher promotional and distribution expenditure compared to their competitors. Successful industrial goods are also more innovative, but show a broader product assortment, pursue more activities of direct marketing, and have similar promotional and distribution expenditure compared to their competitors.

From these studies, the conclusion can be drawn that the effectiveness of different launch strategy types depends on product- and market-related contingencies. However, from an aggregate perspective, the findings support the notion that launch performance usually requires setting clear, well-founded launch objectives, defining a precise target market, and positioning the product in a distinct manner. Significant investments in promotional and distribution expenditures also seem to drive launch performance.

ANTECEDENTS OF LAUNCH DECISIONS

The question as to which background factors influence decisions made during new-product launch has only rarely been addressed in the new-product launch literature. So far, only few studies have investigated antecedents of an effective launch strategy. Hsieh, Tsai, and Hultink (2006) investigated the impact of a firm’s resource configurations on the launch strategies pursued. While strategic and organizational abilities and physical assets seem to be unconnected with an effective launch strategy, the authors find that technological capabilities and societal-network assets and goodwill are crucial resources for companies following a “niche innovators” strategy, while for “mass marketers” only technological capabilities are

relevant. However, pinpointing why firms adopt different launch strategies is only a first step when aiming to identify the antecedents that drive performance through appropriate launch decisions. The link to market performance is investigated by Langerak, Hultink, and Robben (2004) and Talke and Hultink (2009). Langerak, Hultink, and Robben (2004) explored the impact of a market-oriented firm culture on the nature of launch decisions and on new-product performance. While the results show that a market orientation is related positively to the proficiency in market testing, launch budgeting, and the strategic and tactical launch decisions, the mediated model is only supported for the launch tactics.

Talke and Hultink (2009) propose that the capability to successfully launch new products is based on the interplay between the corporate mind-set and the firm's strategic launch decisions. It is argued that performance in launching a new product requires an analytical, risk taking, and aggressive mind-set to set clear and ambitious launch objectives and to proficiently make use of market segmentation and positioning. The results show that the dimensions of the corporate mind-set have a significant impact on most strategic launch decisions, which in turn significantly contribute to market performance. It is found that an analytical posture is driving the setting of clear launch objectives, the selection of target markets, and the positioning of the new product. Risk taking has a significant impact on market segmentation and product positioning, while aggressiveness drives the setting of strategic launch objectives. These findings confirm the importance of investigating antecedents for a successful new-product launch, as the corporate mind-set and also partly the market orientation can serve as background resources that set the framework for successful launch decisions. Despite this, the question as to which antecedents drive a successful launch strategy requires more investigation.

THE MANAGEMENT OF DIFFUSION BARRIERS

Stakeholder opposition as barriers to effective launch decisions and diffusion. Although not explicitly stated in any of the studies reviewed above,

diffusion theory (Rogers, 2003) is the underlying theoretical basis of these approaches to conceptualize an effective launch strategy (*see* DIFFUSION OF INNOVATION). Consequently, the focus is on the potential customers and their adoption decisions. However, such a perspective neglects other stakeholders who can significantly influence the performance of any new product's launch and diffusion, like internal stakeholders, and noncustomer stakeholders from the external market and the broader firm environment, such as suppliers, competitors, and other interest groups. A stakeholder perspective seems to allow a more thorough picture of an effective launch strategy.

In an early conceptual work on creating a marketing hype, Wind and Mahajan (1987) argue for targeted interaction with relevant stakeholders like dealers, suppliers, diffusion agents, and the general public to create a favorable atmosphere before the launch of a new product. According to these authors, the key notion is to sufficiently understand the needs of all relevant stakeholders and address them in an adequate form. However, just recently, Talke and Hultink (2010) detailed the barriers that may arise if relevant stakeholders are not adequately considered and the concrete launch activities that have to be pursued to overcome such barriers.

From an internal perspective, employees involved in new-product launch, like marketing, sales, or service personnel, may expose knowledge and motivation-related barriers opposed to launch objectives (Hultink and Atuahene-Gima, 2000). Negative consequences resulting from motivation barriers may manifest themselves in boycotting activities, like omitting critical launch activities or a purposeful ill-doing of launch tactics. Additionally, frontline personnel may experience a lack of knowledge with respect to the new product to be launched. Such a knowledge gap can lead to activities not matching the launch objectives. An inadequate sales approach toward customers or incorrect declarations vis-à-vis other relevant market partners may hamper launch success (Hultink and Atuahene-Gima, 2000).

Talke and Hultink (2010) propose that from the perspective of the external market, one has to differentiate between market parties generally interested in constructive interaction

and those who intend to compete. Market actors interested in cooperation, like suppliers or complementary producers, face various uncertainties. The major worry is concerning the general strategic and financial worth of the investments that are made by the innovating firm during any cooperation. Information about new-product characteristics and benefits (*see* PRODUCT SPECIFICATIONS) are needed to anticipate market acceptance and to fit the own offering. Moreover, uncertainties exist about the innovating firm's expectations concerning the cooperation modalities (Hallikas, Virolainen, and Tuominen, 2002). If these uncertainties and information deficits cannot be reduced by the innovating firm, the cooperation will not happen or work out as expected. The resulting lack of support constitutes a diffusion barrier, which can impede a successful new-product launch in different ways (Debruyne *et al.*, 2002). A lack of availability of suppliers' components in due time and with good quality will jeopardize the new product's availability in the market (Hallikas, Virolainen, and Tuominen, 2002). Without compatible, value-adding offers of complementary producers, the attractiveness of the new product will decrease and the innovation may not get established as a standard. Without the support of sales agents, the new product's distribution may be endangered; and a lack of service offerings, as consulting, training, or installation by adequate service providers, can impede customer adoption.

Market players intending to compete will try to build diffusion barriers in favor of their own product (Debruyne *et al.*, 2002). Measures may include lowering prices, increasing communication expenditures, modifying the existing product offering, imitating the innovation, or trying to establish another standard. Debruyne *et al.* (2002) find that the characteristics of the launch strategy have a significant impact on both the occurrence and nature of competitive reactions. Competitors fail to respond to radical innovations and to new products that employ a niche strategy. However, they do react to new products that can be assessed within an existing product category and thus represent an unambiguous attack. Both innovative and imitative new products meet with reactions in this case. Competitors are more inclined to react

to the introduction of new products that are supported by extensive communication by the innovating firm. The likelihood of reaction is also higher in high-growth than in low-growth markets. For the innovating firm, the consequences of diffusion barriers set by competitors can extend from reduction of market share to market extrusion.

Stakeholders of the broader firm environment, such as the general public, legal and political institutions, or other interest groups, also face uncertainties about the consequences of the new product and how it fits their own goals. A new-product offering that offends values of interest groups can lead to complaints, protests, or boycotts against the new product. This may result in image loss or legal regulations that can significantly hinder a new product's diffusion (*see* DIFFUSION OF INNOVATION). Overall, opposition of different stakeholder groups can constitute a threat to launch success. Being aware of such potential diffusion barriers is, however, only a first step preceding an active management of such barriers.

Managing diffusion barriers. When comparing the impact of addressing these different diffusion barriers on launch success, Talke and Hultink (2010) find that first of all, barriers related to customers, suppliers, and stakeholders of the firm environment need to be lowered. The activities they propose are on an aggregate level and concern the degree to which the innovating firm interacts with these parties; that is, explicitly addresses them with targeted launch communication or cooperates with them in the preparation of or during a new-product launch. For the group of competitors, Talke and Hultink (2010) find that a balanced launch approach including measures to both lowering and erecting entry and diffusion barriers increases the market performance of new products. Under high uncertainty (*i.e.*, in the case of complex products, and high market and technology dynamics) managing multiple diffusion barriers is of higher relevance than in more unambiguous, clear-cut contexts.

Selectively, authors active in the field of launch strategy have dealt with activities addressing one specific stakeholder group. Exemplary studies with a focus on launch

communication and on managing the firm's frontline personnel will be reviewed in further detail below.

Managing diffusion barriers with launch communication. Several authors view decisions around communication activities as critical to a successful launch as these decisions are most directly responsible for aiding the market acceptance of a new product (Lee and O'Connor, 2003). In a recent article, Michael and Palandjian (2004) confirm that performance in new-product launch increases with spending on launch communication. Apart from the amount of investment in launch communication (Michael and Palandjian, 2004), other studies focus on issues such as the impact of characteristics of communication channels (Hultink *et al.*, 2000), type of communication strategies (Schatzel and Calantone, 2006), or communication content (Talke and O'Connor, 2009) on new-product performance.

A particular communication strategy relevant in the launch context is preannouncement. Preannouncements can be understood as prelaunch communication activities directed at market players including customers, distributors, suppliers, investors, and journalists with the intent to reduce uncertainty in the firm's favor. Preannouncements provide market partners interested in cooperating with the opportunity to better plan, thus deterring a competitor's entry into a market segment, and engendering positive opinions from market players regarding the firm and its intentions (Schatzel and Calantone, 2006). Schatzel and Calantone (2006) found that the more a firm engages in preannouncements, the greater is the favorable bias and interest of various market parties. Lee and O'Connor (2003) examine the effect of different preannouncement strategies (targeting at customer education, anticipation creation, and market preemption) on new-product performance. They find that preannouncements emphasizing customer education lead to higher performance for products that are difficult to adopt. On the other hand, a preannouncement message that focuses on creating anticipation for the new product leads to higher performance for products that provide high superiority to customers.

Concerning launch communication content, Talke and O'Connor (2009) investigate the specific content that facilitates new-product diffusion. They propose a model of three message content dimensions: usability information, technical information, and financial information. Each of these information types is designed to mitigate a set of perceived risks that consumers may experience in the decision to adopt a new industrial product. They find that usability information and financial information are effective in improving market performance, while technical information is countereffective. When launching highly innovative products, usability information is of specific importance, while financial details become less important. For pioneers, communicating the new product's usability is highly effective, while for later entrants using financial information increases performance.

Managing internal diffusion barriers.

The firm's frontline personnel can be seen as the first stakeholder group that needs to be won over to optimize launch performance. Concerning the question of how to effectively manage the firm's sales force, Hultink and Atuahene-Gima (2000) find that in a situation of increased uncertainty, salespeople perform better when their sales manager provides them with feedback on their past performance. As feedback reminds salespeople of the results that they are expected to attain, they may feel less ambivalent about their role, and will be better armed to experiment and take risks in selling the new product. This finding suggests that if salespeople are rewarded on the basis of their outputs, they perform better.

CONCLUSION

Given the widely acknowledged importance of the launch phase, one may expect a thorough understanding of critical launch activities, a sound theoretical basis, and a body of empirical findings substantiating measurement models, performance relationships, contingencies, and antecedents. While in recent years there has been an increasing interest in the last phase of the NPD process, there is still a lack of theory-based launch research. As a consequence,

while much progress has recently been made, there is still ample room to further investigate the activities that a firm should pursue around a new-product launch, resulting in a demand for further research in the areas of conceptualizing launch activities and analyzing related effects.

growth strategies

Michael J. Baker

INTRODUCTION

In a competitive world, the status quo is in a state of constant flux. Standing still is not an option. Only through a process of constant adaptation and renewal can one hope to survive and prosper. It is for this reason that organizations invest in new-product and service development, which is the theme of this volume of the encyclopedia. But, for investment to pay off, it has to add value and generate sales in excess of its costs. And to achieve this, one needs a growth strategy.

From the firm's perspective it is important to distinguish between macroeconomic and microeconomic conditions. Understandably, a firm's primary preoccupation is with the products and services that it offers and the markets that it serves. This is the domain of microeconomics and a firm's performance (growth or otherwise) is determined by its success in "jockeying for position" in competition with other firms serving the same market. However, microeconomic conditions are ultimately subject to the prevailing macroeconomic conditions. Clearly, if the global economy is expanding, growth opportunities are much greater as consumers have more discretionary purchasing power with which to buy goods and services. For individual firms, taking advantage of this is still a challenge. But, at the time at which this is being written, the global economy has suffered a major economic downturn and has moved into recession. In a recession, overall effective demand contracts (growth is negative) but the impact of this will not affect all firms and markets in the same way, and the challenge becomes acute as does the selection and implementation of a strategy.

To address this challenge, we begin with a discussion of strategy and the imperative of growth. Next, we review the growth-vector matrix as a diagnostic framework for identifying alternative strategies available to the firm. These strategies depend largely on the stage at which the industry and its products are in their life cycles – the theme of the next section. The ideas of the growth-vector matrix and product life cycles (PLCs) are then combined in the

diagnostic developed by the Boston Consulting Group, which is reviewed as a basis for examining the options available to the firm at each of its major phases.

THE IMPERATIVE OF GROWTH

While a multidivisional organization might require a "corporate" strategy to coordinate and direct the separate strategies of the strategic business units (SBUs) that comprise it, the great majority of business organizations are SBUs in their own right. When this is the case, then the marketing strategy is both a competitive and a corporate strategy.

According to Arthur D Little,

A strategic business unit—or strategy centre—is a business area with an external marketplace for goods and services, for which management can determine objectives and execute strategies independent of other business areas. It is a business that could probably stand alone if divested. Strategic business units are the "natural" or homogeneous business of a corporation.

Central to the SBU is the *product*, which we define here as a tangible offer the firm makes to the market and which includes quality, range, design, and branding. It also includes services such as delivery, leasing, repair, and training (Doyle, 2000). This is what the producer or supplier offers to a potential customer in exchange for something else (usually money), which the supplier perceives as equivalent to or of greater value. It follows that product strategy lies at the very heart of corporate and marketing strategy.

In broad terms, an organization has only a limited number of strategic options available to it. Leaving aside the possibility of withdrawing from a market, the focus of these options is growth – the subject of this article. According to the AMA American Marketing Association dictionary entry for "growth strategy":

Market share expansion is the prime objective under this strategy, even at the expense of short-term earnings. The firm may seek to expand market share through a number of alternative routes. First, the firm may seek new users who may previously have been loyal to

2 growth strategies

other brands, or tended to switch, or were not users of the category at all. The second way in which the firm can expand its market share is to expand usage by current users; for instance, by identifying and promoting new uses.

This is a very narrow view that is restricted primarily to a firm with a share of a mature market for a product or service and largely ignores the need for a firm to continually update its offerings if it is to remain competitive (*see* MANAGING MATURE PRODUCTS).

In "Value-based Marketing," the late Prof. Doyle (2000) devotes a complete chapter to what he calls "*the growth imperative*." In his view, management should make growth a top priority as it is essential for creating shareholder value because of its potential for increasing the net present value of future cash flows. Despite this, many managements prefer to emphasize rationalization of the present business because not only is it easier and less risky, it also has a more immediate effect on increased profits and cash flow. However, such effects may be purely short term and so threaten the future survival of the company. Of course, by then, the management responsible may well have retired! By contrast, a growth strategy is likely to be more risky in that it involves seeking to anticipate what customers will want in the future and adjusting the firm's product market mix to anticipate these future changes. This is not to discount the important contribution that rationalization may make in terms of improving both efficiency and effectiveness. But, for long-term survival a growth strategy is essential.

To succeed, a growth strategy requires a firm foundation from which to develop. Invariably, this firm foundation is to be found in the trust and loyalty of the firm's existing customer base as success in the short term depends very much upon repeat purchase and word-of-mouth recommendation. These two activities comprise the first two steps of nine in what Doyle calls "*the ladder of growth*." These nine steps are defined as follows:

1. increasing customer retention rate
2. increasing customer share
3. gaining new customers
4. developing new products and services

5. entering new markets
6. exploring new distribution channels
7. increasing international growth
8. negotiating acquisition and alliances
9. exploring growth outside current industry boundaries.

Each of these steps is then described in some detail with an explicit discussion of the tactics and activities associated with them. Given the space limitations for this article, a simpler conceptualization consisting of fewer steps seems appropriate. Such a conceptualization is to be found in the growth-vector matrix first proposed by Ansoff (1957). (In passing it should be noted that earlier in the same year Johnson and Jones (1957) had published a very similar "technology market matrix." However, this has attracted relatively little attention, probably because this matrix too contains nine options or alternative strategies, whereas Ansoff's matrix contains only four.)

THE GROWTH-VECTOR MATRIX

The "growth-vector matrix" is a familiar analytical device to be found in most textbooks dealing with marketing strategy and is closely associated with the name of Igor Ansoff. The original version first appeared in the September/October 1957 issue of the Harvard Business Review in an article entitled "Strategies for diversification" but was subsequently revised in his book on corporate strategy published in 1965. In Figure 1, we offer an adaptation of his original idea, which retains a two-by-two format but conceptualizes it as reflecting the interaction between demand and supply, as represented by customers and technology/products, both current and "new". This results in four basic alternatives, which Ansoff described as market penetration, market development, product development, and diversification. The following are defining characteristics of these alternatives:

1. *Market penetration*: The company seeks increased sales for its present products in its present markets through more aggressive pricing, promotion, and distribution. By these means, the firm seeks to increase the volume of consumption by its existing

| <div>Supply</div> <div>Demand</div> | Current Technology / Products | New Technology / Products |
|-------------------------------------|-------------------------------|---------------------------|

- customers, convert nonusers to users, and attract exiting users from its competitors.
2. *Market development:* The company seeks increased sales by taking its present products into new markets. This may be achieved by expanding into new geographical areas, for example, exporting, and/or by opening up new distribution channels.
 3. *Product development:* The company seeks increased sales by developing improved products for its present markets. In doing so the firm is seeking to achieve the same objectives as a penetration strategy with the added potential for entering new markets resulting in diversification.
 4. *Diversification:* The company seeks increased sales by developing new products and new markets. Where the firm attempts to do this without prior knowledge/experience of either the product (technology) or market (customer) the risks are far greater than when it “migrates” into this state via a strategy of product or market development.

If we compare this classification with Doyle’s growth ladder, we can see that market penetration is equivalent to steps 1–3, market development embraces steps 5–7, while step 4 is equivalent to product development. Step 8, acquisitions and alliances, may relate to the current product–market mix or may be addressed at step 9, which is equivalent to diversification. As can be seen from this figure, the AMA definition is focused primarily on what Ansoff terms *market penetration* and, to a lesser degree,

market development. As such, it ignores both new-product development and diversification, which are major growth strategies.

A more appropriate and dynamic approach is to consider the management of a product as it progresses through its life cycle and recognize that a different emphasis and marketing mix is called for in each of the major phases – introduction, growth, maturity, and decline. Thinking on these issues was strongly influenced by the work of Theodore Levitt.

GROWTH AND PRODUCT LIFE CYCLES

Theodore Levitt was one of the most influential marketing thinkers of the second half of the twentieth century (see also PRODUCT LIFE CYCLE). Central to his writings is a concern with the marketing concept and competition at the industry/firm level. Many would regard his “marketing myopia” as the catalyst that heralded the adoption of a marketing orientation as a key to competitive success. In the opening paragraph, he asserts as follows:

Every major industry was once a growth industry. But some that are now riding a wave of growth enthusiasm are very much in the shadow of decline. Others which are thought of as seasoned growth industries have actually stopped growing. In every case the reason growth is threatened, slowed, or stopped is not because the market is saturated. It is because there has been a failure of management.

4 growth strategies

In a nutshell, his argument was that management had failed to adapt to new and improved ways of satisfying customers by emphasizing the products and services they offered for sale rather than the needs that they served. Underpinning this argument was the view that technological innovation offered the opportunity to create new and better products that would both substitute for existing products and stimulate new demand and growth. In other words, technologies and the products derived from them have a life cycle each phase of which called for different marketing mixes and managerial action.

While some have questioned the value of the PLC concept, there can be no doubt that it offers a useful description of the phases through which a successful products pass from their initial introduction to their eventual withdrawal from the

market place. Once the characteristics of these phases have been identified, it becomes possible to recommend courses of action best suited to their operational management as illustrated in Table 1.

THE BOSTON “BOX”

Although rarely acknowledged explicitly, the notions of the growth–vector matrix and the PLC are combined in what is commonly referred to as “*the Boston Box*” (see also GE/MCKINSEY MATRIX).

In discussing product policy and strategy, and especially new products, the focus is frequently on a single product. In reality, most firms have a range or portfolio of products each of which may be at a different stage in its life cycle. It is recognition of this that led the Boston

Table 1 Product life cycle: implications for marketing.

| <i>Product Life Cycle</i> | <i>Introduction</i> | <i>Growth</i> | <i>Maturity</i> | <i>Decline</i> |
|---------------------------|---------------------|-----------------------------|--------------------------|-------------------|
| Characteristics | | | | |
| Sales | Low | Fast growth | Slow growth | Decline |

Consulting Group to propose a diagnostic procedure analyzing the comparative and collective performance of different products in a firm's range. It was this that was to become famous as the "Boston Box." While several variants of the Boston Box have been proposed, they all rest on two fundamental propositions, namely, the competitive value of market share depends on the structure of competition and the stage of the PLC.

The importance of taking into account the stage that a product (or industry) has reached in its life cycle is fundamental to the whole concept and practice of marketing. As the marketing concept makes clear, survival depends upon understanding and satisfying the needs of customers, and realization and acceptance of the fact that, over time, these needs will change, often owing to the action of marketers; hence the importance of the product life cycle. If, then, we accept the inevitability of the PLC

it follows that, even where we are concerned with a basic product such as steel with a life span of decades, we would be unwise to assume that any particular formulation or, more important, method of manufacture is immune from competition and replacement. To guard against this possibility, product differentiation has become a key competitive strategy and new-product development an essential activity, so that even the overtly single-product firm should have a range of variant products at different stages of development.

Like the growth-vector matrix, the Boston Box uses two parameters – market growth, which is a proxy for the stage in the PLC, and market share, which is a proxy for profitability. Its purpose is to distinguish the four basic categories of product, the desired movement of businesses over time, and the likely movements of cash between them. A version of this matrix is presented as Figure 2.

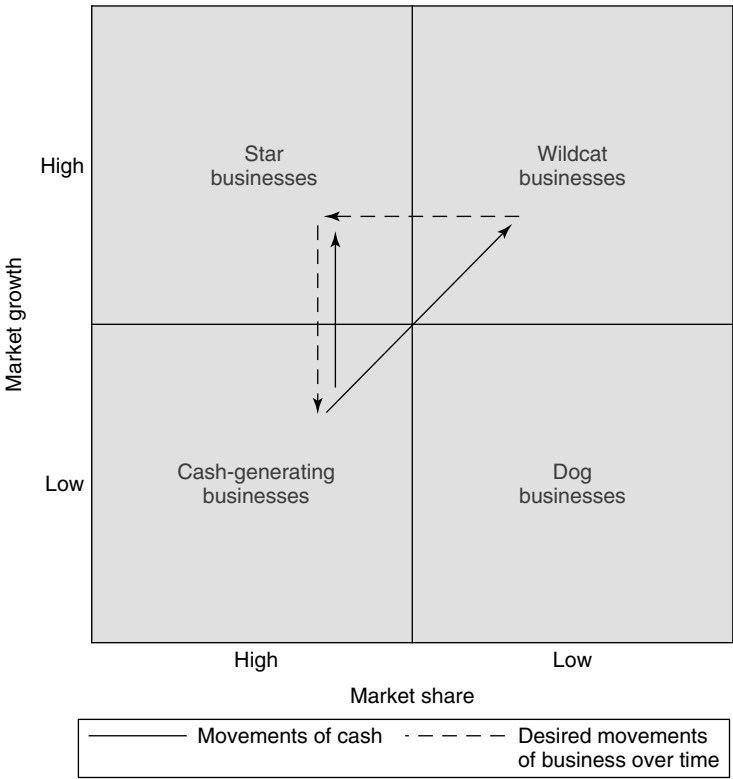

Figure 2 The Boston box (reproduced with permission from Conference Board, The (1974) 'Why Products Fail').

Wildcat businesses (also known as *problem children*) represent products at the beginning of their life cycle where hopes run high, and expectations of rapid growth and profitability encourage the firm to invest heavily in its new product despite uncertainty as to its eventual success. Clearly, the hope is that by doing so the product or business will get onto the rapid-growth curve when sales expand exponentially, and costs and overheads decline rapidly because of economies of scale and growing experience. At this stage of market development, competition is fierce as firms jockey for position to become “stars,” and seek to secure cost and price advantages, which will enable them to secure a dominant share of the new market.

Cash cows represent products that have survived the shakeout of the growth phase when firms compete aggressively with one another and have become established players in a mature market. To displace these dominant products, new and better alternatives are required and a new cycle of innovation occurs. As new wildcat products become established and grow, demand for mature products begins to fall and move into decline in terms of their market share. However, it is important to recognize that the decline in market share does not necessarily equate with a decline in growth. For example, in the packaging industry during the 1950s, new synthetic plastic packaging materials began to substitute for the more traditional packaging materials such as paper, board, and tinplate. Today the latter materials comprise a much smaller share of the total market for packaging materials but, owing to overall growth of demand for packaged goods, the demand for paper, board, and tinplate today is far higher than it was 50 years ago.

PRODUCT DIFFERENTIATION AS A GROWTH STRATEGY

On the basis of their visits to a number of leading companies, Deschamps and Ranganath Nayak (1993) take the view that such companies succeed competitively because they believe there is no such thing as a “commodity” product (*see also* PRODUCT DIVERSIFICATION). Even in basic industries such as minerals, chemicals, and agribusiness “suppliers can always find ways to differentiate their products from those of their

competitors”. The corollary is that if one fails to differentiate, the only basis for competition is cost and price.

Deschamps and Nayak propose five basic strategies for competing through products. These they designate as follows:

1. competing through product proliferation
2. competing through value
3. competing through design
4. competing through innovation
5. competing through service.

Competing through product proliferation. This strategy was pioneered by General Motors in the 1920s and 1930s in its battle with Ford. Once thought to be the preserve of large, rich companies, it is now recognized as reflecting the company’s development effectiveness and seen as one of the most effective strategies for all companies. Japanese companies were seen as being particularly adept at proliferation strategy in which they took “a scattershot approach to the marketplace,” which is contrasted with Western companies that have a “rifle mentality.” Thus Japanese firms will launch many new products simultaneously or in close succession and use market response to determine which to support and which to withdraw – what, elsewhere has been called “*trial and error marketing*.” By contrast, Western firms seek to define their single shot and its target much more precisely with the result that if they miss they have to repeat the procedure again.

Key exponents of a proliferation strategy are Honda in motorcycles who overwhelmed Yamaha’s challenge in the early 1980s with 80 new models and 113 product offerings against Yamaha’s 34 and 37 in an 18-month period; Sony, whose Walkman technology could not be protected so that 80% of the market went to competitors until Sony introduced 150 new models in the period 1981–1989 and regained preeminence with over 40% market share; and Procter & Gamble, who introduced numerous variants of its Pampers brand to fight off competition.

Competing through value. Offering high quality at low cost is seen by some to be the ultimate strategy (*see* VALUE PROPOSITION).

“In the hands of daring entrepreneurs such as Henry Ford, this strategy spurred the great consumer revolution of the twentieth century.” Deschamps and Nayak identified two discrete approaches – *continuous improvement* and *radical restructuring*

“Many companies in traditional industries operate instinctively within a relatively simple quality/cost trade-off model. In this way of thinking, there is a single, fixed, direct relationship between quality and cost. Any significant improvement in the product, whether in design features, or even quality ‘feel’, necessitates a proportional increase in costs.” Many firms are seen to support this view.

By contrast, Toyota has “a mental model of multiple and movable trade-off curves. This alternative view allows for the systematic planning and introduction of process improvements that dramatically shift any given quality/cost curve.” Shifting from one quality/cost curve to another is achieved by a number of complementary approaches including process efficiencies in development and manufacturing, systematic design improvements, and “a persistent tracking of inefficiencies and waste at all levels.”

The merits of these alternative approaches have been widely recognized and adopted in what Senge (1990) describes as the “*learning organization*.” The approach of radical restructuring is typified by IKEA, which “revolutionized furniture design, manufacturing, and retailing by rethinking the entire business system of its industry from product concept to distribution.” By offering excellent design and product quality backed up by strong customer service and a liberal return policy for its range of self-assembly furniture, IKEA offers superior value when compared to conventional furniture manufacturers/retailers.

Competing through design. For manufacturers who compete through design excellence, “... design is not a cosmetic add-on but a means of expressing their corporate identity in the marketplace and establishing their products as synonymous with quality” (see *PRODUCT DESIGN*). This is achieved “by designing products that are

- aesthetically appealing
- safe and pleasing to touch and use

- immediately intelligible and easy to operate
- easy to install, handle, store, clean, and maintain
- easy and economical to manufacture.”

Success in design calls for a combination of engineering design – from the inside out – with aesthetic design from the outside in.

Competing through innovation. Few companies compete consistently through innovation. Those that do include Black & Decker, Canon, DuPont, 3M, Merck, Phillips, and Sony.

Because of the risks of innovation, fast followers often reap the rewards lost by the true innovator (see *FIRST-MOVER ADVANTAGE*). “However, fast followers usually succeed only when the original innovator lacks the market position or financial strength to fully exploit its innovation. Few fast followers succeed against a healthy, well positioned innovator.”

Innovation strategies may be incremental or breakthrough and may be either top down or bottom up in their origins and processes (see *RADICAL INNOVATION; INNOVATION TYPOLOGIES*). Radical (breakthrough) innovations may be the result of a conscious policy. But, according to Deschamps & Nayak, “top-down breakthroughs happen only when these are all in place:

1. a top management with a strong vision of where and how to innovate and the capability to communicate and mobilize people to make it happen;
2. a strong technological culture and world-class capability to develop innovation enabling technologies and new proprietary product concepts;
3. a very clear sense of the customer (through a combination of research and intuition) and the ability to translate product concepts into attractive, saleable products;
4. an ability to combine mutually reinforcing innovations (for example, in product and in manufacturing process).”

That said, bottom-up breakthroughs probably dominate (if for no other reason than that there are many more of them). However, incremental innovation is more commonplace particularly in

the top-down mode where far more R&D policies exist. For bottom-up incremental innovation to occur the right culture has to exist, which establishes a climate that encourages innovations and provides mechanisms for facilitating them.

Competing through service. While customers regard product and service as “two faces of the same coin” most manufacturers give greater emphasis to the product and see services as adding costs rather than value. This perception is being rapidly eroded with the growing recognition of the importance of customer service.

The authors conclude: “Underlying all these diverse ways to compete is the realization that products are created through a *process*.”

Leveraging new-product growth. On introduction to a market, a new product has to overcome at least three kinds of potential resistance before it is likely to “take off” and grow rapidly. These may be characterized as technological, infrastructural, and behavioral. Lele (1992) illustrates their effect by reference to the market for microwave ovens. The first designs of microwave ovens were introduced in 1957 but were large and expensive. The technology needed considerable refinement. Secondly, microwave cooking calls for special containers and most preprepared and convenience foods were not packed in the right materials. The infrastructure had to develop to make microwave meals available. Third, until more women began to enter the workforce there was an absence of a sufficiently powerful precipitating circumstance, convenience, to prompt the behavioral response. Lele describes this as the “emerging” phase during which typically there may be many, often small, participants with a wide variety of products and marketing mixes largely due to the low resistance to entry.

In some senses, we may regard the emergent or introductory phase as a period of trial and error, which will lead to the evolution of a dominant design widely accepted by both producers and users. It is this dominant design that usually triggers the rapid-growth phase and sees a switch in emphasis from product development to process innovation. Sellers and buyers are now agreed on the desirable attributes of the new product and competitive advantage resides in being able to produce and market the new product in the most

efficient and effective way. During the growth phase, Lele (p. 201) argues that “the emphasis should be on identifying the most likely and profitable product/market areas for introducing flankers, niche products, or complements.”

During the growth phase, competitors may choose to follow one or other of three broad alternative strategies. They can attempt to develop a second standard, can adopt the first standard and compete head-on, or can identify potential niches and concentrate on getting into them first. Developing a second standard has major cost implications and, in effect, is equivalent to launching a new product, which would have to survive launch and introduction while competing with the first standard in its rapid-growth phase. This is not exactly an easy or attractive proposition. Competing head-on also requires considerable resources but is often the approach taken by large firms pursuing the strategy of the fast second who delay entering the market until the onset of rapid growth indicates it is propitious for them to climb on the bandwagon. For smaller players this is not a viable alternative. Most competitors will seek to develop specialist niches or complementary products and so ride on the coat-tails of the industry leader.

SUSTAINING DIFFERENTIATION

It is clear that a new product enjoys a competitive advantage because it is differentiated (*see* COMPETITIVE ADVANTAGE). It begins to lose this advantage as soon as similar or improved versions are introduced to the market by other firms. It is generally accepted that only two basic strategies are available – cost leadership and differentiation, although Porter and others identify focus as a special case of differentiation. Cost leadership is a function of size and market share and is, by definition, a strategy limited to one (monopolist) or very few (oligopolists) in any given market. It follows that for the great majority of innovators the only viable strategy is differentiation. With a new technology, further developments and improvements are possible, so product development remains a major source of differentiation during the growth phase, with the other elements of the marketing mix playing a supporting role. However, when maturity sets in further, significant product improvements are

no longer available, and competition revolves entirely around manipulation of the price, place, and promotional variables.

As Levitt pointed out in his famous article "Exploit the product life cycle" (*Harvard Business Review*, Nov–Dec 1965): "The ensuing fight [during the market growth phase] for the consumer's patronage poses to the originating producer an entirely new set of problems. Instead of seeking ways of getting consumers to *try the product*, the originator now faces the more compelling problem of getting them to *prefer his brand*" (p. 33). In part, such preference will depend upon having a better, or equivalent product, when first-mover advantages may lend added value, that is, the company's name is most strongly associated with the new product. But, if the firm's product is seen as being of much of a muchness with all the new competitive offerings then price, promotion, and distribution will assume increased importance in helping to differentiate the product.

There is considerable evidence to suggest that many innovators fail to reap the full reward of the growth phase. One reason for this is that the firm's own growth cycle may not reflect that of the industry as a whole. Indeed, the sudden upsurge in growth engendered by the rush of imitators seeking to cash in on the new market opportunity may stall the innovator's own growth curve. As Levitt (1965) comments, "for the originating company its growth stage now becomes truncated. It has to share the boom with new competitors. Hence the potential rate of acceleration of its own take-off is diminished and, indeed, may actually fail to last as long as the industry's" (p. 86). It is for this reason that monitoring both the product and industry life cycles is so important in devising strategies to maintain the firm's competitive edge. As the kind of analysis described by Levitt makes clear, the impact of competition, which is a major driver of rapid growth, will have negative consequences for the originator, *unless* they heed the warnings of life-cycle analysis and take deliberate steps to stay ahead of the game and control market growth.

A classic example of a firm doing this was Pilkington with the introduction of float glass. This process, patented by them, was a major technological breakthrough which offered a product far

superior to that made by traditional methods. As a known need innovation with high relative advantage, high compatibility, low complexity (in use), high divisibility (buy a square meter or a square kilometer), and excellent communicability, it was a surefire winner. Everyone wanted it. Clearly, there was no way Pilkington could cope with such a demand on a global scale. Equally clear was the fact that major competitors like St Gobain and Corning would do everything they could to replicate the process. Rather than encouraging a competitive response Pilkington defused it by offering licenses to major producers in other countries and taking a royalty off every square meter sold.

Armed with the hindsight that PLC analysis offers, innovators can preplan their competitive moves so as to avoid being outmaneuvered and overtaken by the competition. To quote Levitt again, "advance planning should be directed at extending, or stretching out, the life of the product. It is this idea of *planning in advance* of the actual launching of a new product to take specific actions later in its life cycle – actions designed to sustain its growth and profitability – which appears to have great potential as an instrument of long-term product strategy" (p. 88).

Much of Levitt's analysis then focuses on extension or stretching strategies which mainly come into play when a product reaches maturity. However, bearing in mind the earlier comment that the onset of competition and rapid growth may truncate the originator's own growth cycle, it is quite likely that the originator will move into the mature phase of their PLC while the industry life cycle is still growing. This, too, may be a source of competitive advantage as the innovator may be able to consolidate their position by adopting extension strategies while the remaining competitors slug it out for a share of a market, which still appears to be growing because of the aggressive competition.

Although profit margins usually decline through the maturity phase products at this stage of their life cycle almost invariably comprise the backbone of an established firm's business and generate most cash for reinvestment in the future. Firth (1980) cites seven reasons given by Rogers, which account for declining profit margins:

10 growth strategies

1. There is an increase in the number of competitive products leading to overcapacity and intensive competition.
2. Market leaders are under growing pressure from smaller competitors.
3. There is an increase in R & D to find better versions of the product.
4. Cost economies are used up.
5. There is a decline in product distinctiveness.
6. Declining sales result in dealer apathy and disenchantment with a product.
7. The loyalty of those first to adopt begins to waver with changing market composition.

In turn, and because of this profit erosion, the industry tends to stabilize as a set of well-entrenched competitors all seeking a competitive advantage. This they usually attempt to do by adopting one of four basic strategies, which have been characterized as follows:

1. an offensive or “take-off” strategy
2. a defensive strategy
3. a recycle strategy
4. a stretching and harvesting strategy.

An offensive strategy has as its objective a major extension of the PLC and will often lead to one or more periods of renewed growth followed by stabilization at an overall higher level of sales. Perhaps the best-known example of this strategy is that reported by Levitt for nylon in which four quite distinct approaches were used to extend the life cycle:

1. promoting more frequent usage among current users;
2. promoting more varied usage among current users;
3. attracting new users;
4. developing new uses for the basic material.

In terms of Ansoff’s growth-vector matrix, approaches 1 and 2 above are equivalent to market penetration, 3 is equivalent to market development and 4 to new-product development. Research by Baker and Hart (1987) into the sources of competitive success in UK industry confirmed that the most successful firms pursued strategies of market penetration,

new-product development, and market development simultaneously – precisely the approach taken by Du Pont with nylon.

Where it is not possible to develop new uses or markets for a product, it becomes necessary to protect one’s existing share of the market through a defensive strategy. This is often referred to as *dynamic adaptation* and involves manipulation of the nonproduct elements of the marketing mix – price, distribution, and promotion.

A recycling strategy is most often found in the markets for fast-moving consumer goods (FMCG), but is also applicable to consumer durables and industrial products. Like a defensive strategy, recycling seeks to preserve a product’s market share against erosion through a preplanned series of relaunches based upon one or more elements of the mix, for example, product improvements, repackaging, new advertising campaign, different channels, and so on.

Stretching or harvesting strategies are most common for products with high market shares and little or no direct competition. Because of its dominant position such a product requires below-average marketing support on a unit basis and so enjoys above-average profit margins.

SUMMARY

When the shouting is over, one fact is clear: what differentiates perennially great companies from others is the products they sell (Deschamps and Nayak).

We argued that for long-term survival a growth strategy is essential and followed Doyle (2000) in identifying nine options available for achieving this. These were reduced to the four alternatives suggested by the growth-vector matrix based on an idea proposed by Ansoff (1957), namely, market penetration, new-product development, market development, and diversification.

Next, we introduced the concept of the PLC and the notion that a different marketing mix is required for each of its four major phases. This idea was then linked to the proposal that firms need a product “portfolio” with a range of products at different complementary phases

of their life cycle as suggested by the “Boston Box.”

Underlying a successful growth strategy is product (goods and/or services) *differentiation*, and we followed Deschamps and Nayak’s five basic strategies for achieving this – through product proliferation, value, design, innovation, and service – and concluded by proposing how to leverage new-product growth and sustain differentiation.

managing mature products

Susan Hart

INTRODUCTION

In his seminal article “Marketing Myopia,” Theodore Levitt proclaimed that “every declining industry was once a growth industry,” emphasizing the commercial imperative for management to scan the horizon for technological, social, and competitive developments that might erode the dominant or growth position of products at a given point in time (see GROWTH STRATEGIES). Indeed, there are numerous examples that the onslaught of intensive competition in the growth stage of a product’s life cycle (PLC) often results in the onset of premature maturity for organizations that launched the innovation in the market. A pervasive characteristic of this tendency is that although industry-wide sales may still increase, the innovator’s sales can flatten, requiring an alternative strategy from those used in previous stages of the PLC. The example of Intel illustrates the point well. Although a leader in terms of microprocessor market share, there persists a pattern of steeply declining prices for each generation of new processors (Hutt and Davidson, 2005). This indicates that, despite a market that is still growing, there are clear symptoms of product maturity accompanied by an alteration in marketing mix elements. But is price reduction the optimum response? Here, we explore what causes the slowdown in growth, the characteristics of maturity, and the options available in the mature phase of product and market development.

WHAT IS THE NATURE OF MATURITY AND WHAT ARE ITS CAUSES?

Classical life cycle theory postulates that the market growth rate decreases as more and more of the available customers buy the product. When most of the available customers have bought the product (or service), that is, at the point of market saturation, the rate of growth decreases. At this juncture, sales continue to the point where sales volume is equal to the replacement rate, plus any natural growth in market size

due to increase in population. This is typically the longest single stage of the product or the service life cycle. It is at this stage that products and services often become the “cash cows” and one feature of this is that they become the focus of the product and the brand managers whose existence is predicated upon the continuance of the product. The success of the product and the brand managers in prolonging this stage of the life of a product or service is the very reason critics of the PLC have dismissed the concept as not having any practical value. That said, classical PLC diagrams trace the progress of an innovation in the *absence* of managerial intervention. Its strength as a conceptual tool is that by considering the stage of a product or service in its life cycle, managers can define the strategic options available to them and so design appropriate strategies and tactics. See PRODUCT LIFE CYCLE for more details.

Another feature of slowing growth when a product approaches maturity is the profit *margin* reduction. The notion of margin is important here as mature products usually comprise the core of a company’s product portfolio and hence the “cash cow” referred to above. However, during the elongated stage of the life cycle, margins can become increasingly narrow, which has been attributed by Rogers as long ago as 1962, to the following factors (see DIFFUSION OF INNOVATION):

1. increasing number of competitive products, leading to overcapacity and intensive competition;
2. market leaders under growing pressure from smaller companies;
3. strong increase in RESEARCH & DEVELOPMENT to find better versions of the product;
4. cost economies used up;
5. decline in product distinctiveness (see COMPETITIVE ADVANTAGE);
6. apathy and disenchantment in the distribution chain due to the product’s declining sales; and
7. changing market composition where the loyalty of those first to adopt begins to waver.

These seven features are interrelated and often the tactics taken by firms accelerate

2 managing mature products

the transit of product markets from maturity to decline. The reaction of suppliers in a market where sales growth is declining, and there is increasing realization of the limits of growth, is countered by attempts to find ways around these limits. Typically, once growth in a market has slowed, further expansion can only come from intense competition for market share, using tactics such as product proliferation, discounting, own-label manufacture, and so on in an attempt to consolidate and protect their share. Global examples of these tactics in mature product markets include soft drinks, confectionery, and automobiles, whereas in services, telecom-provider competition has resulted in a wide array of service types, pricing strategies, and bundling techniques.

Although a prime characteristic of this stage in a product or service's life cycle, market saturation is not simply a case of having reached all potential consumers of the product in question. Sales' growth rates slow down even during the earlier stages of the PLC, before all potential users have tried the product. This is because, by the time laggards (the final tranche of customers to buy the product or the service) adopt the product or the service, those customers who bought the product early in its life cycle (termed "*innovators*" and "*early adopters*") are likely to have moved on, switching to other, possibly completely new, products. Thus, as the uptake of the product or the service decelerates, players in the distribution channel become less inclined to offer it, not only because of slower sales rates but also because of reduced margins compared to newer products still experiencing growth. Particularly in the case of physical products, where retail space is at a premium, retailers work to stock the assortment of product lines that optimize the return from the space available. Inevitably, slow-moving products will have their shelf and display space availability cut in favor of those whose growth curves suggest a fast-moving rate of sales and consequent higher margins. A good example of this can be found in the mobile phone handset margin, where specialist distributors exhibit new handset models to boost the uptake of particular service providers. This incurs a knock-on effect in that comparative lack of availability causes customers

to buy the more easily available alternatives. Thus, a reduction in shelf and display space for mature products is likely to accelerate their demise. A further consequence is that the retailer may use the fact of dwindling sales to encourage tactics such as price cuts to incentivise purchase, reducing the profitability of the product even more. Put together, these tendencies can bring ever-intensifying pressure on mature brands.

In spite of these pressures, mature products are also known as *cash cows*, as for at least part of their maturity, they are considered to be assets to the firm and a necessary component of a balanced portfolio and have commanded much attention in terms of how best these assets can be managed. Indeed, most books on marketing management take the management of products and services in maturity as the "norm," discussing and exemplifying the permutations of the marketing mix and how they might be combined to best advantage. In this context, it is the development and marketing of new products, at best a solitary chapter in these books, that is singled out as a case differentiated from this norm. Such concentration has served to prolong the mature stage of the PLC beyond what could be regarded as its "natural" course, using two groups of strategies: offensive and defensive. Each is dealt with in turn below.

STRATEGIES FOR MANAGING MATURITY

Offensive strategies. An offensive or "take-off" strategy is, as the name implies, one designed to propel new energy into the sales of a mature product. The goal of such strategies is, in effect, to attempt to stimulate new growth in sales by new strategies. Various frameworks exist to categorize what these might entail. Two similar categorizations appeared within a few months of each other in the *Harvard Business Review* (September–October 1957 and May–June 1957). Ansoff's growth-vector matrix has become very well known – outlining the four *corporate* strategies of product penetration, product development, market development, and diversification (see PRODUCT DIVERSIFICATION). Johnston and Johnston's matrix, although less well known, is a 3×3 matrix, the unit of analyses of which are markets and technologies (both product and

process) offers a total of nine options as shown in Table 1. The original examples have been replaced by more contemporary instances from consumer markets and serve well as an organizing framework (*see also* GE/MCKINSEY MATRIX). Essentially, this matrix uses three conditions of technology deployment (no technological

change, improved technology, and new technology) and three market targeting conditions (no market change, strengthened market, and new market). Setting aside, for the purposes of this, the three options that call for a new technology (replacement, product-line extension, and diversification), which imply

Table 1 Johnston and Johnston matrix.

| Increasing Technological Newness | | | |
|--|---|---|--|
| No Market Change | | Improved Technology | New Technology |
| | | Objective: to utilize more fully the company's present scientific knowledge and production | Objective: to acquire scientific knowledge and production skills |
| | | Reformulation To maintain an optimum balance of cost, quality, and availability in the formulas of present company products, for example, G 2-Screen Nintendo Lite | Replacement To seek new and better ingredients or formulation for presenting company products in technology not employed by the company now, for example, Playstation 3 |
| Strengthened Market | Remerchandizing | Improved Product | Product-line Extension |
| Objective: to exploit more fully the existing markets for the company products | To increase sales to consumers of types now served by the company, for example, Coke; Pepsi, McDonald's, Dove | To improve present products for greater utility and products merchandisability to consumers, for example, Dove "Upside down" Deodorant | To broaden the line of products offered to present consumers through new technology, for example, Playstation portable (PSP); iPod Nano (video) |
| New Market | New Use | Market Extension | Diversification |
| Objective: to increase the number of types of consumers served by the company | To find new classes of consumers that can utilize present company products, for example, breakfast cereals as evening healthy snack; Nintendo for "brain train" | To reach new classes of consumers by modifying present products, for example, iPod shuffle to extend iPod use to younger age groups | To add to the classes of consumers served by developing new technical knowledge, for example, Nintendo Wii |

4 managing mature products

the development of another *new* product, leave us with five possible courses of action: remerchandizing, new use, reformulation, improved product, and market extension (*see* PRODUCT-LINE STRATEGIES). All of these may be considered as offensive strategies, although it is important to acknowledge that there may be instances of their deployment that also allow them to be identified with defensive strategies when used in combination with measures such as price adjustments or product augmentation (described later).

Remerchandizing. “Remerchandizing” can be achieved in a number of ways and has been long espoused by writers and practitioners alike. Drawing on some classical examples, Levitt’s (1965) article on how to exploit the PLC used the example of the development of nylon by DuPont, to illustrate options such as promoting more frequent usage of the product among current users and developing more varied usage of the product among current users. At first glance, these options may seem identical, but they are nuanced. To explain further, it is interesting to turn to another classic piece, written by Twedt in 1964, which presents the concepts of heavy and light halves of usage concentration. Looking at the annual purchase concentrations in Table 2, Twedt categorized the annual sales among users and nonusers of the products. Using Lemon-Lime, the first item on the list, as an example, 42% of households are not consumers. Taking the households that do consume the product and dividing them into two groups, we see that the “light half” only accounts for 9% of consumption, whereas the “heavy half” accounts for a staggering 91%. This striking difference was found in many different categories, offering a choice to the mature product marketer – is resource to be spent on convincing heavy users to use still more of the product or on persuading the lighter users to increase their use. This reasoning illustrates the difference between the two remerchandizing options, namely, that more varied usage may be more appropriate for the heavy half, while more use may be more achievable with the light half, and each would require slightly different elements of the marketing mix. Returning to nylon, the choices facing marketers would have been the promotion of the product to light users (younger women, women in warmer

climates) or to promote more varied use by heavier users by introducing product variants based on color and different textures. Consider the distinction between Diet Coke and Coke Zero, the former arguably merchandized for the heavy half (women) and zero for the light half (men). The factors influencing such a decision relate to the assessment of how difficult or problematic it is to increase usage among light users or nonusers. For example, Playboy’s foray into purses, pencil cases, and other accessories for a young teen market, while commercially sensitive, has been much criticized as a way of remerchandizing the brand. Moreover, changing behavior, although central to the mission of marketing, is both complex and expensive, and the received wisdom is that reformulation of a product to new nonusers/new users’ needs and wants is the better and more market-oriented course of action. Of course, alternative strategies are moving into new (geographical) markets that have previously not had access to the product – in other words, new market entry.

New uses. New uses of the existing product may be found, in view of the difficulties in persuading people to change behavior within the confines of current products available to them. The life cycle of nylon was extended by DuPont by modifying the basic material to a series of new uses – tire cord, textured yarns, carpet yarns, and so on. The illustration of this product in Levitt’s article shows how restricting the original formulation to miscellaneous and circular knit applications, its sales by weight would have flattened out at 50 million pounds in 1962 as opposed to 10 times that amount across the totality of formulations of the material.

Other prominent examples of new uses include the application of Teflon (another DuPont product) beyond its original applications to include razor blades and the development of many uses of hemp from a fiber application (clothing and construction materials) to embrace specialty paper pulp, geotextiles, and cosmetic products.

Reformulation. Reformulation may be required to assist in the adoption of the new use, as well as to encourage current segments or markets to buy more products. The generational

Table 2 Annual purchase concentration in 18 product categories.

| | <i>Nonusers</i> | <i>Users</i> | |
|----------------------------------|-----------------|--------------|------------|
| | | Light half | Heavy half |
| Households | 42% | 29% | 29% |
| Lemon-lime | 0 | 9% | 91% |
| | 22 | 39 | 39 |
| Colas | 0 | 10 | 90 |
| | 28 | 36 | 36 |

development of mobile phone handsets as well as portable game consoles provides examples of the ongoing exploitation of a company’s technological and market knowledge. In its most recent incarnation, the DS Lite harnesses multiple technologies such as wi-fi connectivity

and touch-screen technology in a “double screen” variation on the original product.

Similarly, the inexorable changes in MP3 and MP4 are intended to position products across a variety of mobile-music consumer groups, including keep fit segments, commuters, and

home listeners. Design and styling can be used to greatly extend market use and even applications without requiring a fundamental change in the basic product. In addition to the changes in specification across the iPod range, color and styling have been particularly relevant and echo an article in *The Sunday Times* (18 December 1994), where Hugh Pearman exemplifies the concept and practice of reformulation through the changes made, over time, to the electric toaster. In his words,

Toasters have been around as long as most people have had a domestic electricity supply, which is 80 years. The present generation is lined up on display in an electrical or department store near you. What does the act of choosing one say about our design awareness?

All toasters are not exactly the same under the skin but they are as near the same that it makes no difference. They are boxes that nearly grill the bread, waffles, Pop-Tarts, or whatever between little electric fires and eject them just before they start to burn: an easy, well-proven technology, whether it is purely mechanical or microchip controlled. The last fundamental innovation in toaster design was in 1927, when the Sunbeam Company of America marketed the first pop-up model. Since then, there has been little to do, design-wise, except to alter the styling according to the tastes of the times. That meant round and bulbous in the 1950s, square and angular in the 1960s, decorated in the 1970s, elongated in the 1980s, and bulbous again in the 1990s.

Designers try to give toasters the equivalent of sunroof and antilock brakes – wider slots, double slots, “cool wall” designs, and the like – but cannot get away from the fact that one needs only two controls: a push-down lever and a timer. Upgrades merely dress up a timeless concept and are anyway almost all adopted immediately by other manufacturers.’

The aim of the article is to illustrate that while the product remains functionally the same, it can be redesigned, styled, and reconfigured to encourage increased sales and sales to new and different market segments.

Product improvement. Comprehension of the PLC leads to the ability to preplan courses

of action, which anticipate changes in competitive and market behavior and which when left unchecked could further slow down the growth of mature products. In consumer electronics, all the major players make use of product improvements, which are more substantial than the reformulations described above. Even in this high-technology product market, major technological breakthroughs can be easily copied, despite the use of patents. Patents themselves will often tell competitors all that they need to know to make a “me too” product. If a new product is not patented, then value analysis and competitive benchmarking of the new product soon reveal the majority of its secrets to others. It has been estimated that any major technological innovation is fully understood worldwide within 18 months of its first market entry. This can be readily seen in portable music products – in the 1980s, the Walkman was quickly replicated and in more recent times, MP3 clones have been introduced in quick succession.

To respond to these competitive pressures, key players in the market have used improvement strategies very effectively, by means of the introduction of frequent new products derived directly from the original product concept. For example, Sony introduced around 150 versions over a period of 10 years during the 1980s, ensuring that every possible niche and microsegment was covered, making it less economically viable for competitors to do the same. In a similar pattern, Sony introduces a major new feature on its camcorders at approximately six-month intervals. In both cases, the basic architecture of its products has remained constant, with each new product change launched in succession to keep a step ahead of key rivals. It must be noted that this strategy has its own limitations – it is about the improvement of a product category or technology where an organization can reap profits from fast, efficient, and knowledgeable exploitation of technologies in which it has developed considerable expertise. There is a risk, however, that concentrating on current technologies leads to blindness toward new technologies. It could be argued that Sony has not enjoyed continued level of success in the mobile-music market since the advent of MP3 technology, perhaps due

to a focus on old technology. Similarly, MP3/4 manufacturers will need to pay heed to the latest trends in the industry with an increasing number of wi-fi-enabled cellular phone handsets, which feature integrated music download features, set to double in volume by the end of 2010, compared to January 2008 (<http://www.itfacts.biz>). What must be guarded against, while keeping the product improvements going, is a myopic perspective on the next generation of music-listening techniques and devices.

Market extension. Market extension is a way of increasing sales of a product in a new market or market segment without a major development of the product itself. In reality, from a marketing perspective, some modification may be required to ensure that the marketing effort is not wasted by promoting a “production” orientation. Examples include the migration of breakfast cereals “positioning” from breakfast to snack foods bolstered by “weekly plans” for eating the product with different combinations as suggestions for times of the day other than breakfast, and the promotion of “brain training programs” for handheld gaming devices such as Nintendo, to extend their use from a youth/young adult market to more mature market segments. The toy and games market provides numerous examples of how traditional games, such as Monopoly, have extended markets for their products – for example, the junior market, as well as multiple boards for international appeal.

Thus far, the strategies discussed have been aimed at attracting *additional* customers to mature products. These are known as *offensive strategies* because they aim at taking sales from competitive products. It is also important, however, to continue to nurture current customers and mature-product market customers, so defensive strategies are also important; these are discussed in the following section.

Defensive strategies. During the later decades of the twenty-first century, levels of competition in mature markets became increasingly intense and with that dawned the realization that customer retention was equally – some contended more – important than customer creation. Where a market is saturated, by definition, all customers

have purchased the product and so the only way to grow a customer base is by winning new customers at the expense of the competition. Not only is this a zero-sum game but it could also be portrayed as a negative-sum game because it costs more to create or win a customer than to keep one. The rule of thumb estimates confirm this in a number of ways:

- the need to spend 5 times as much on marketing to win a customer than that required to keep one happy;
- a 5% retention of the customer base that is normally lost through “churn” can improve profitability between 25 and 80%; and
- most customers will not switch from their current supplier for less than a 10% improvement in the value.

These alternative suggestions reinforce the adage that if marketing is “selling goods that do not come back to people who do,” a large part of marketing effort must be about making sure those customers do, in fact, come back. In other words, it is repeat purchase and maintenance of the relationship, which is the key to long-run competitive advantage. It was this definition that F. Stewart De Bruicker and Gregory L. Summe probably had in mind when they wrote their article entitled “Make sure your customers keep coming back” in the Harvard Business Review article of 1985. De Bruicker and Summe address the question of how the onset of maturity affects buyer–seller relationships. They examine what steps sellers should take as buyers change from what they call “inexperienced specialists” to “experienced specialists.” As customers gain experience with a product or service, their knowledge grows and attitudes can change, and the authors propose four strategies for dealing with this: strengthening account management practices, augmenting the product, improving customer services, and lowering prices.

While a technology associated with a new product or indeed a new product category is not well understood with the customer base, buyers are dependent upon sellers for advice on how to use a product and for after-sales service and support to get the maximum value from it. If customers become more familiar

with the product and it becomes more reliable, this dependency on the seller declines. As De Bruicker and Summe (1985) observe, “As customers gain familiarity with a product they find manufacturer’s support programs to be of declining value. Their buying decisions become increasingly price-sensitive. They unbundle into components the products they once purchased as systems and open their doors to suppliers who sell on price and offer little in the way of product support. Even the most remote observer, once instructed can spot the pattern” (p. 93).

A firm that already enjoys the status of a supplier to a customer (also known as the *in-supplier*) usually has competitive advantage over the rival out-supplier, due to the perceived risks and costs of switching. Research amongst consumers suggests that they will often stick with a known product and supplier through habit and inertia even when they gain no particularly strong benefit or satisfaction from the habit. On the other hand, should something occur that causes active dissatisfaction, the habitual buyer may consider a change. Therefore, provided the in-supplier does not become complacent and continues to work at the relationship, using any of the four strategies cited earlier, it should be able to defend its position indefinitely.

Strengthening Account Management Practices. Strengthening account management practice directs resource and effort to maintain a multilevel relationship between seller and buyer and so keep purchasing decisions under review by general managers in senior positions. The involvement of top management is designed to prevent the product declining into commodity status when the purchaser (experienced specialist) becomes more knowledgeable and able to play one supplier off against another to secure the best price, delivery, and so on. In high-technology industries with rapid change and frequent new-product development, multilevel relationships are easier to develop and sustain. In fact, under the customer-active paradigm of new-product development, suppliers are frequently members of their customers’ own product development team and so enjoy a privileged status. The challenge is to ensure the continuation of these relationships into the mature phase.

Product Augmentation. Product augmentation, the second defensive strategy, is described in some detail by Levitt (1980). He acknowledges that what constitutes product augmentation and added value may well vary from customer to customer, and the successful use of this approach will depend heavily on the seller’s ability to identify courses of action that will enable the maintenance of differential competitive advantage and so avoid the rigors of price competition. There are numerous bases for augmentation – packaging changes, product delivery changes, changes in the distribution networks, and availability of the product to the customer. In recent years in the food industry, for example, repackaged products have stabilized falling sales in dairy, vegetable, and soft drinks. Hutt and Davidson (2005) explain how both Intel and Hewlett Packard have stayed competitive by focusing marketing on the additional value customers get from their technologies, rather than just the core attributes of the functionality of the products. A recent study reported in the *Sloan Management Review* described an example of augmentation in a Portuguese shoe manufacturing company that, by making business units more modular, they were able to respond to market niches more quickly and become a supplier of sample shoes to retail chains.

Customer Service Strategy. Customer service strategy, the third approach suggested by De Bruicker and Summe, is particularly appropriate for laggards who enter the market when the product is already mature. Although the product may have been around for quite some time, it is still new to the first-time buyer who may well have delayed entry because of “techno-fear”. For such laggards, distribution through nonspecialist outlets that cater to novice buyers, customer training and education in how to use the product, and after-market support like IBM’s Helpline will all add value for the new buyer.

Lowering Prices. Lowering prices is the response that may have to be offered when the product has become so standardized and commonplace that financial incentives or discounts will be essential to maintain buyer loyalty. Perversely, however, a very low price

may discourage buyers by increasing the buyer's perceived risk – “if it is that cheap it cannot be any good.” Such an attitude is often found in the case of suppliers who offer much lower prices than their competitors. However, price competition can only be afforded by the few or be used as a short-term tactical weapon, as it erodes margins and ultimately destroys the cash income required for investment in future developments. The objective is to avoid price competition through a differentiation strategy: differentiation of anything – but especially the product.

CUSTOMER RELATIONSHIP MANAGEMENT (CRM)

Customer relationship management (CRM) is a topic worth cross referencing in the context of managing mature products because, theoretically at least, it is an approach for closely monitoring customer buying behavior, developing and nurturing relationships with customers, and ensuring that the products and services on offer do match with customer's requirements. However, many commercial exchanges do not involve any particular relationship between seller and buyer other than a straightforward commercial transaction. Moreover, if a firm sets out to *manage* a relationship, this implies a desire to exercise power and control, which is antithetical to the very notion of a “relationship”. These and other criticisms of CRM are beyond the scope of this article, but mention has been made because CRM is indeed a strategy suited to the maintenance of relationships, in the way that account management, described above, seeks to aid customer retention in mature markets.

CONCLUSION

As the market enters late maturity, the choice is seen as resting between withdrawal and growth. At this stage, the market is still very substantial and subject to little change. It offers little or no attraction for new entrants except for those with a radically new approach who may be prepared to attack the inertia and complacency of markets

at this stage of their life cycle. Such attacks rarely come from within the industry. Business history is replete with examples of new technologies that displaced their predecessors: vinyl flooring displaced linoleum; cars and aircraft displaced trains and passenger ships; and MP3 technology displaced tape and disc technology. In each of these cases, the new product was not developed by those producing the incumbent products. In several cases, the opportunity did exist for the new product to be developed by those already enjoying market maturity but they either ignored the opportunity or did not wish to cannibalize their brands. Few reclaimed their prior position once they had allowed the new players to enter the market with their new products that satisfied demand. That is the picture for the entrenched supplier in a market that is in late maturity. Their job is twofold – manage maturity, keep the income flowing into the organization, but keep an eye on the future, monitor competitive threats, and be prepared to switch to new products and technologies once an irreversible decline sets in.

leadership roles in product development

Abbie Griffin

Successful innovation requires multiple capabilities (Figure 1). Invention occurs in the FRONT END OF INNOVATION (FFE), before there is a well-formed concept. It is where technical possibilities are created and matched to customer problems and market needs, requiring technical competence, creativity, and market insight. Gaining project acceptance requires developing a business plan for the proposed product or service and shepherding that plan through the firm's funding and staffing process. This task fundamentally is one of managing the politics of the firm. Then, getting the product to market is a matter of project execution and implementation through formal processes, such as the Stage-Gate® (see THE STAGE-GATE IDEA TO LAUNCH SYSTEM).

Because invention, project definition and acceptance, and process execution each require different competencies, economic theory suggests that the most efficient management of the innovation process would be through a division of labor (see also ORGANIZING FOR INNOVATION) (Schumpeter, 1934). Indeed, in a traditional new-product development (NPD) setting, these stages are driven by *inventor* technologists, *champions*, and *implementers*, respectively, each with different sets of capabilities as identified in Table 1 (Griffin *et al.*, 2007).

DEFINITIONS

Inventors typically have technical degrees, and frequently have advanced training and degrees in their field. These individuals have enough depth and breadth of technical understanding to solve critical problems and they exhibit creativity in the way they solve those technical problems (Tidd *et al.*, 1997). They merit and seek a measure of autonomy in defining how they approach inventing (Kerr *et al.*, 1977), have a commitment to their work and their profession, and may identify more with their profession and technical peers than with their firm. Inventors aspire to be ethical, unemotional, and unselfish in the conduct of their activities. Most frequently, inventors reside in the R&D laboratory, or in an

engineering development group. While highly creative technically, inventors have little market or business knowledge, and frequently operate in isolation of others (O'Connor and Rice, 2005).

A *champion* puts himself on the line for an idea and uses any and every means of informal tactics and pressure to make it succeed (Schon, 1963). Champions usually do not create innovative ideas, but find them elsewhere in the firm (Markham and Aiman-Smith, 2001). Effective champions have technical competence, knowledge about the company, knowledge about the market, drive and aggressiveness, and political astuteness (Chakrabarti, 1974). They are most likely to use a transformational leadership style (Howell and Higgins, 1990).

Project managers, or *implementers*, organize the execution of the project and ensure that each task and milestone is completed on time, and within budget. They are task oriented (Turner and Miller, 2005), yet also have the ability to influence others on the team (Crawford, 2003). The most frequently used influence tactics by project managers are rational reasoning, consultation, and inspirational appeals (Lee and Sweeney, 2001). Higher project success is associated with project managers who exhibit higher proficiency in planning, a more participatory and motivating management style, and skills in the technology domain (Thieme *et al.*, 2003).

While the vast majority of innovation projects divide the total labor among these different "specialist" individuals, some innovation projects are substantially the responsibility of just one individual, who has capabilities that allow him or her to drive all the phases of the project. These individuals, termed "*innovators*," invent, champion, and facilitate implementation. Innovators tend to be very driven systems thinkers, who are creative and curious about many different topics. They have a somewhat idealistic worldview – they want to solve important real-world problems that improve business outcomes and peoples' lives, where "important" is defined by people external to the corporation, like potential customers (Hebda *et al.*, 2007). They take the perspective that technology is a means to an end, and that new technology must make money for the corporation. Innovators understand

2 leadership roles in product development

☑ primary skill; • secondary sensitivity.

the reality of the political process of project acceptance. They prefer to use facts and other positive influencing mechanisms in managing the politics of innovation. Their process focuses on using extensive customer interaction to fully understand potentially interesting problems and extensive exploration of possible solutions, prior to launching into the implementation phase. They act in whatever role is needed at any particular point in time, much like entrepreneurs. Finally, innovators follow the new product into the marketplace, helping market and sell it. Overall, their process focuses on the tasks that are completed prior to a typical formal NPD implementation process, and extends beyond that process as well (Griffin *et al.*, 2007).

COMMENTARY

Table 2 summarizes the major differences among these types of NPD leaders. Because of their differences and the different specialist role that each prefers to take in innovation, it would seem that different management strategies need to be

developed to allow each type of specialist to function in top form. It is unlikely that someone adept at managing inventors will be adept at managing champions, or that a good manager of implementers could also manage innovators. And yet, inventors, champions, and implementers need to interact effectively for a technology to proceed from capability to successful product in the marketplace.

new-product forecasting

Kenneth B. Kahn

New-product forecasting is the endeavor to come up with a meaningful estimate on which to guide new-product development and product launch decision making (see LAUNCH STRATEGIES). New-product forecasting is not necessarily a straightforward endeavor in practice and is often characterized as quite difficult (Mahajan and Wind, 1988) and error prone (Kahn, 2002). Employing appropriate techniques coupled with a well-structured new-product forecasting process appears to result in a greater propensity for new-product forecasting success. This emphasizes the need to recognize that new-product forecasting goes beyond technique application into process management (Kahn, 2006).

TYPES OF NEW-PRODUCT FORECASTS

Several types of new-product forecasts are possible and can be broken down in terms of *potential* versus *forecast*, and *market* versus *sales*. *Potential* represents a maximum attainable estimate, whereas *forecast* represents a likely attainable estimate. *Market* represents all companies within a given industry marketplace, whereas *sales* pertains to only the respective focal company. New-product forecast definitions are provided below:

- *Market potential*: the maximum estimate of total market volume reasonably attainable under a given set of conditions.
- *Sales potential*: the maximum estimate of company sales reasonably attainable within a given market under a given set of conditions.
- *Market forecast*: a reasonable estimate of market volume attainable by firms in that market under a given set of conditions.
- *Sales forecast*: a reasonable estimate of company sales attainable within a given market under a given set of conditions.

During the new-product forecasting effort, one or all of the above may be of interest. For example, early in the process, the forecasting focus is the market potential. Such forecasts

are normally in dollars and are used to address the question of whether this is a good opportunity to pursue. During concept generation and pretechnical evaluation stages, forecasts investigate sales potential in answering the question of whether this is a good idea for the company to pursue. Entering technical development and launch phases, unit sales forecasts would become critical in order to plan for the launch and to ensure adequate supply through the channel. Product testing during technical development and market testing during the commercialization would help qualify key assumptions and better estimate unit demand and sales revenue.

FORECASTING TECHNIQUES

There are numerous forecasting techniques available, with no one technique found to be the best. Among the multiple ways in which to categorize techniques, one way is to categorize forecasting techniques as judgmental techniques, quantitative techniques, and customer/market research techniques. Albeit showing only a sample of techniques, the below lists the more popular techniques associated with each of these three categories.

Judgmental techniques. Judgmental techniques represent techniques that attempt to turn experience, judgments, and intuition into formal forecasts. Six popular techniques within this category include jury of executive opinion, sales force composite, scenario analysis, Delphi method, decision trees, and assumptions-based modeling:

- *Jury of executive opinion*: a top-down forecasting technique where the forecast is arrived at through the ad hoc combination of opinions and predictions made by informed executives and experts.
- *Sales force composite*: a bottom-up forecasting technique where individuals (typically salespeople) provide their forecasts. These forecasts are then aggregated to calculate a higher level forecast.
- *Scenario analysis*: an analysis involving the development of scenarios to predict the future (Huss and Honton, 1987; Huss, 1988). Two types of scenario

2 new-product forecasting

analysis include exploratory and normative approaches. Exploratory scenario analysis starts in the present and moves out to the future based on the current trends. Normative scenario analysis leaps out to the future and works back to determine what should be done to achieve what is expected to occur.

- *Delphi method*: a technique based on subjective expert opinion gathered through several structured anonymous rounds of data collection (Woudenberg, 1991; Gordon, 1994). Each successive round provides consolidated feedback to the respondents, and the forecast is further refined. The objective of the Delphi method is to capture the advantages of multiple experts in a committee, while minimizing the effects of social pressure to agree with the majority, ego pressure to stick with one's original forecast despite new information, the influence of a repetitive argument, and the influence of a dominant individual.
- *Decision trees*: a probabilistic approach to forecasting where various contingencies and their associated probability of occurring are determined – typically in a subjective fashion. Conditional probabilities are then calculated, and the most probable events are identified (Ulvila, 1985).
- *Assumption-based modeling*: a technique that attempts to model the behavior of the relevant market environment by breaking the market down into market drivers. Then by assuming values for these drivers, forecasts are generated. These models are also referred to as *chain models* or *market-breakdown models* (Crawford and Di Benedetto, 2003; Kahn, 2007).

Quantitative techniques. Quantitative techniques are broken into the three subcategories of time series, “causal”/regression modeling, and other quantitative techniques. Time series techniques analyze sales data to detect historical “sales” patterns and construct a representative graph or formula to project sales into the future. Time series techniques used in association with new-product forecasting include

- *Trend line analysis*: a line is fit to a set of data. This is done either graphically or mathematically.
- *Moving average*: a technique that averages only a specified number of previous sales periods.
- *Exponential smoothing techniques*: a set of techniques that develop forecasts by addressing the forecast components of level, trend, seasonality, and cycle. Weights or smoothing coefficients for each of these components are determined statistically and are applied to “smooth” previous period information (Makridakis *et al.*, 1997; Mentzer and Bienstock, 1998).
- *Looks-like analysis (analogous forecasting)*: a technique that attempts to map sales of other products onto the product being forecast. Looks-like analysis is a popular technique applied to line extensions by using sales of previous product line introductions to profile sales of the new product.
- *Diffusion models*: models that estimate the growth rate of product sales by considering various factors influencing the consumer adoption process (*see* BASS MODEL). Considerations taken into account include the rate at which mass media (the coefficient of innovation) and word of mouth (the coefficient of imitation) affect lead users, early adopter, early majority, late majority, and laggard customer segments. Different types of diffusion models exist including the Bass model, the Gompertz curve, and the logistic curve, which are examples of some popular diffusion models. Diffusion models are also referred to as *technology S-curves* (*see* TECHNOLOGY S-CURVE) (Mahajan, Muller, and Bass, 1990; Lilien, Rangaswamy, and Van den Bulte, 1999; Mahajan, Muller, and Wind, 2000).
- *Autoregressive moving average (ARMA)/Autoregressive integrated moving average (ARIMA) models*: a set of advanced statistical approaches to forecasting, which incorporate key elements of both time series and regression model building. Three basic activities (or stages) are considered: (i) identifying the model, (ii) determining the model's parameters, and (iii) testing/applying the model. Critical

in using any of these techniques is understanding the concepts of autocorrelation and differencing. ARMA/ARIMA models are also referred to as *Box-Jenkins techniques* (Makridakis *et al.*, 1997).

“Causal”/regression modeling techniques use exogenous or independent variables and through statistical methods, develop formulas correlating these with a dependent variable. The term “causal” is very loosely used because these models are predicated on correlational relationships and not true cause and effect relationships. Four popular techniques within this subcategory include

- *Linear regression*: a statistical methodology that assesses the relation between one or more managerial variables and a dependent variable (sales), strictly assuming that these relationships are linear in nature (Neter *et al.*, 1996). For example, price may be an important driver of new-product sales. The relationship between price and the quantity sold would be determined from prior data of other products within the product line and then used to predict sales for the forthcoming product.
- *Nonlinear regression*: a statistical methodology that assesses the relation between one or more managerial variables and a dependent variable (sales), but these relationships are *not* necessarily assumed to be linear in nature.
- *Logistic regression*: a statistical methodology that assesses the relation between one or more managerial variables and a binary outcome, such as purchase versus nonpurchase. A logistic regression model calculates the probability of an event occurring or not occurring.
- *Event modeling*: often a regression-based methodology that assesses the relation between one or more events, whether company initiated or nonaffiliated with the company, and a dependent variable (sales). For example, a promotion used with prior product launches would be analyzed and the bump in sales caused by this promotion statistically determined. The expected bump in sales would be correspondingly mapped to the sales of the new product.

The other category contains those techniques that employ unique methodologies or represent a hybrid of time series and regression techniques. A sample of these forecasting techniques include

- *Expert systems*: typically computer-based heuristics or rules for forecasting. These rules are determined by interviewing forecasting experts and then constructing “if-then” statements. Forecasts are generated by going through various applicable “if-then” statements until all statements have been considered.
- *Neural networks*: advanced statistical models that attempt to decipher patterns in a particular sales time series (Adya and Collopy, 1998). These models can be time consuming to build, difficult to explain, and in many cases, the models are proprietary.
- *Simulation*: an approach to incorporate market forces into a decision model. “What if” scenarios are then considered. Normally, simulation is computer based. A typical simulation model is Monte Carlo simulation, which employs randomly generated events to drive the model and assess outcomes.

Customer/market research techniques. Customer/market research techniques include those approaches, which collect data on the customer/market and then systematically analyze these data to draw inferences on which to make the forecasts. Four general classes of customer/market research techniques include

- *Concept testing*: a process by which customers (current and/or potential customers) evaluate a new-product concept and give their opinions on whether the concept is something that they might have interest in and would likely buy (*see* CONCEPT TESTING). The purpose of concept testing is to proof the new-product concept.
- *Product use testing*: a process by which customers (current and/or potential customers) evaluate a product’s functional characteristics and performance (*see* PRODUCT TESTING). The purpose of product use testing is to proof the product’s function.

4 new-product forecasting

- *Market testing*: a process by which targeted customers evaluate the marketing plan for a new product in a market setting. The purpose of market testing is to proof the proposed marketing plan and the “final” new product.
- *Premarket testing* (see PRETEST MARKET MODELS): a procedure that uses syndicated data and primary consumer research to estimate the sales potential of new-product initiatives (Urban *et al.*, 1983; Fader and Hardie, 2001). Assessor and BASES are two proprietary new-product forecasting models associated with premarket testing. BASES is commonly employed in the consumer products goods industry.

While there are a number of forecasting techniques available, it is important to realize that not all are appropriate for every forecasting situation. Qualitative techniques are quite adaptable, but very time consuming; they would not be appropriate in situations where a severe time constraint exists. Quantitative techniques require data, and rely on the critical assumption that current data will correspond to future states; if these are not feasible, quantitative techniques would not be meaningful. Customer/market research tools are time consuming and expensive to perform. Budget constraints could seriously hamper what degree of customer/market research may be applied. A “toolbox” approach is therefore recommended for applying new-product forecasting techniques.

NEW-PRODUCT FORECASTING ACCURACY

Even with a plethora of techniques, new-product forecasting is characteristically associated with low accuracy (high forecast error). Research shows that the overall average accuracy across the six types of new products is around 58%, with the accuracy of cost improvements generally at 72%; product improvement forecasts at 65%; line-extension forecasts at 63%; market extension forecasts at 54%; new-category entry (new-to-the-company) forecasts at 47%; and new-to-the-world products at 40% (Kahn (2002); these mean values of new-product forecasting accuracy were collected by asking

respondents to indicate the average forecast accuracy achieved one year postlaunch). The nature of these accuracies data reaffirms that newer markets are more troublesome to forecast (i.e., market extensions, new-category entries, and new-to-the-world products), than those situations where a current market is being served (i.e., cost improvements, product improvements, and line extensions).

One of the underlying reasons for low accuracy is the multiple organizational biases that impinge on the new-product forecasting endeavor and cause unnecessary error. Naturally, a new-product forecast should be developed with a keen eye toward realism and presented to management regardless of whatever outcome shown, but seldom does this happen. Various research studies have documented the impact of organizational biases on new-product forecasting (Tyebjee, 1987; Forlani *et al.*, 2002; Bolton, 2003). While it is very unlikely that new-product forecasting will be free of all biases owing to the need to rely on judgment, understanding the persistent types of biases can allow for necessary procedures that enable transparency of new-product forecasting figures and sounder new-product decision making. When “systematic biases” are identified and properly mitigated, the chance for a new-product forecast to be more “on target” increases.

THE NEW-PRODUCT FORECASTING PROCESS

Applying techniques appropriately and addressing organizational biases that surround new-product forecasting mandate a process approach toward new-product forecasting. In doing so, the new-product forecasting process should highlight critical uncertainties inherent in developing the new-product forecast such as cannibalization effects and market penetration. The process also should designate what data need to be collected to address these uncertainties. A process approach to new-product forecasting further mandates the continuous building on experiences from prior new-product forecasts, cross-functional communication (especially with marketing), and customer feedback, thereby enabling

organizational learning and understanding on which to make a credible and realistic forecast.

Assumptions management is an important part of the new-product forecasting process. Accordingly, the new-product forecasting process should clearly specify assumptions and make them transparent so that there is company understanding of what underlies these assumptions. After launch, a tracking system would closely monitor and control these assumptions to determine if forecasts will come to fruition or deviate significantly.

As part of a successful new-product-forecasting endeavor, successful companies have realized that new-product forecasts should not be point forecasts, but rather, be presented as ranges. These ranges typically become more narrowed as the product approaches and enters the launch phase. For example, pessimistic, likely, and optimistic cases could be connected with the monitoring and control of assumptions to determine which scenario is playing out. Best-in-class companies also construct databases to collect, track, and reflect on new-product rollouts, especially those in consumer packaged goods industries. Such internal databases are crucial for the validation of new-product forecasting assumptions, as well as for documenting new-product forecasting accuracy. Tying the internal database with syndicated data, market share, and competitor data can enable more robust analyses related to brand preferences, price elasticities, and geographic rollout scenarios.

innovation typologies

Rajesh K. Chandy and Jaideep C. Prabhu

Innovation, like love, is a many-splendored thing. Whether in the form of a shiny new gadget sought out by eager consumers, or a new technique that saves businesses time and money, or a new service that destroys the value of existing services, innovations come in many forms and affect our lives in different ways. This article examines the dimensions of innovation, and presents a means of classifying innovations.

By definition, all innovations have an element of novelty in them: they are different from what existed before. Yet, all innovations are not the same. Indeed, scholars have over the years proposed a number of different innovation typologies, or ways of classifying innovations. By distinguishing among the many typologies of innovations, we can better manage their development and better predict their sources and their impact. To this end, this article first describes and defines some of the prominent typologies of innovations that scholars have highlighted in the literature. These typologies have generally existed in isolation from each other in the literature. We note some of the commonalities among these typologies, and then propose a metatypology (or typology of typologies) that might serve as a unifying framework for the study and management of innovation (*see also* RADICAL INNOVATION; PRODUCT PLATFORMS; PRODUCT MODULARITY).

WHAT TYPES OF INNOVATION EXIST IN THE LITERATURE?

Table 1 presents a list of the prominent types of innovation that have been described in the literature. In this section, we define each of the types of innovation listed in Table 1, and illustrate them with examples. This section highlights the sheer variety of innovations that exist, and have been studied in the literature.

A product innovation involves the commercial introduction of a product that is new to customers (Schumpeter, 1934). A service innovation involves the commercial introduction of a service that is new to customers (*see* SERVICE

INNOVATION MANAGEMENT). The introduction of the Kodak Brownie in 1900 is an example of a product innovation: it offered cheap and easy use of photography to adults and children alike. FedEx and UPS are examples of service innovations: they enabled customers to deliver documents and packages overnight. A process innovation is one that involves the use of a new approach to creating or commercializing products or services (*see* PROCESS INNOVATION). An example of a process innovation is Henry Ford's use of the assembly line in the manufacture of automobiles.

A technological breakthrough is a product, service, or process that involves scientific principles that are substantially different from those of existing products, services, or processes (Chandy and Tellis, 1998). An alternate label for such an innovation is platform innovation (Sood and Tellis, 2005). The first electronic cameras were technological breakthroughs, since they used a core technology—electronic imaging—to take photographs, in contrast to existing cameras that relied on celluloid roll technology to take photographs.

A component innovation is a new product, service, or process that uses new parts, modules, or materials, but relies on the same core technology as existing products, services, or processes (Tellis and Sood, 2008). For example, in the field of data recording, magnetic tapes and floppy disks differed in the components and materials they used, though they were both based on the core technology of magnetic recording.

An architectural innovation (Henderson and Clark, 1990) or design innovation (Tellis and Sood, 2008) involves the reconfiguration of the linkages and layout of components, but relies on the same core technology as existing products, services, or processes. For example, floppy disks decreased from 14 to 8 inches in 1978, to 5.25 inches in 1980, to 3.5 inches in 1985, and to 2.5 inches in 1989, though each was based on magnetic recording (Christensen, 1997; Tellis and Sood, 2008).

A business model innovation involves systemic changes to the value proposition offered by a product or service, and to the cost structure incurred by the firm offering it (Velu, Prabhu, and Chandy, 2009). These changes are systemic as they involve changing

Table 1 A Meta-Typology of Innovation.

| <i>Dimension of Novelty</i> | | | | |
|-----------------------------|------------|--|-----------------------------|---|
| | | <i>Concept</i> | <i>Customer</i> | <i>Company</i> |
| Feature | Attributes | Product/service/ process innovation | Market breakthrough | New to the firm innovation |
| | | Technological break- through/platform innovation | Disruptive innovation | Organizational/ administrative/ management innovation |
| | | Component innovation | | |
| | | Architectural/design innovation | | |
| | | Business model innovation | | |
| | Effects | Drastic innovation | Discontinuous innovation | Competence-destroying innovation |
| | | Revolutionary innovation | Disruptive innovation | Competence-enhancing innovation Disruptive innovation |

multiple elements of the marketing mix and cost structure at the same time. An example of a business model innovation is Amazon.com. Amazon.com is an innovation that, relative to bricks and mortar bookstores, involves changes to the product (a far greater assortment than any bricks and mortar book retailer), distribution (books available everywhere all the time through the Internet), price (lower prices in general), and promotion (access to online customer reviews). It also involved a reduction in the cost of the firm's offering through lower overheads and greater economies of scale.

A drastic innovation (Reinganum, 1985) or revolutionary innovation (Caselli, 1999; Rosen, 1991) is one that makes current products obsolete. For example, electronic calculators made slide rules obsolete.

An innovation that is a market breakthrough provides substantially higher customer benefits per dollar than existing products, services, or processes, but is based on the same core technology as existing products, services, or processes (Chandy and Tellis, 1998). An example is cable television with signal compression technology that allows a significantly larger number of channels to be transmitted to customers than before, while using existing cable technology.

A radical innovation is one that employs substantially new technology and offers substantially higher customer or user benefits relative to existing products, services, or processes (Sorescu, Chandy, and Prabhu, 2003). A radical innovation combines the technological novelty of technology breakthroughs, and the dramatic improvements in customer and user benefits evident in market breakthroughs. As such, radical innovations tend to be fairly rare. However, they can have powerful effects on the fates of individual firms and entire industries (Chandy and Tellis, 1998, 2000). An incremental innovation is one that involves only minor changes to technology or minor improvements in benefits.

A disruptive innovation (Govindarajan and Kopalle, 2006a, p. 15; Christensen, 1997) introduces a different set of features, performance, and price attributes relative to existing products, making it an unattractive combination for mainstream customers at the time of product introduction because of inferior performance on the attributes these customers value a high price—although a different customer segment may value the new attributes. Subsequent developments over time, however, raise the new product's attributes to a level sufficient to

satisfy mainstream customers, thus attracting more of the mainstream market (Govindarajan and Kopalle, 2006a, p. 15). As Govindarajan and Kopalle (2006b, p. 199) note, "Canon's introduction of slower but inexpensive tabletop photocopiers in the late 1970s relative to Xerox's high-speed big copiers is an example of disruptive innovation. The tabletop copiers were rapidly accepted by small businesses and individuals who appreciated the convenience and price despite poor resolution. At the time of their introduction, the mainstream market (larger companies) still preferred the large copiers because of speed, resolution, collation, and so on. However, over time, further developments in small copiers have allowed Canon to improve quality, speed, and features and offer them at a price point that is sufficient to satisfy the needs of mainstream market."

A discontinuous innovation is one that requires customers to establish different behavior patterns (Robertson, 1967, p. 16). It alters existing patterns of use or creates new patterns of use (Robertson and Gatignon, 1986). Typewriters and microwaveable foods were discontinuous innovations, since they changed longstanding patterns of use and behavior among customers.

A new to the firm innovation refers to the adoption of a product, idea, or behavior by a firm that had not previously adopted the innovation (Booz, Allen, Hamilton, 1982). New to the firm innovations that involve the adoption of new management principles, processes, and practices are referred to as *administrative innovations* (Damanpour, 1991) or *organizational innovations* (Hage, 1999), or *management innovations* (Birkinshaw, Hamel, and Mol, 2008). For example, the adoption of electronic banking by financial institutions and of total quality management practices by manufacturing firms both represent new to the firm innovations. A new to the world innovation, in contrast, represents the first time an innovation is introduced commercially in any marketplace (MacLaurin, 1950).

A competence-destroying innovation is one that requires new skills, abilities, and knowledge in the development and production of a product relative to those held by existing firms in an industry (Tushman and Anderson, 1986, p. 442). As Tushman and Anderson (1986)

note, a competence-destroying innovation either creates a new product class (e.g., xerography or automobiles) or substitutes for an existing product (e.g., diesel vs steam locomotives; transistors vs vacuum tubes).

A competence-enhancing innovation is an order of magnitude improvement in price, performance, or efficiency that builds on existing know-how within a product or process class (Tushman and Anderson, 1986, p. 442). Such innovations substitute for older technologies, yet do not render obsolete skills required to master the old technologies. For example, electric typewriters represented a competence-enhancing innovation relative to mechanical typewriters.

WHAT DIMENSIONS UNDERLIE THESE VARIED TYPES OF INNOVATIONS?

The extensive literature on innovation typologies can sometimes resemble a Tower of Babel with different terms used to refer to similar concepts and, conversely, similar terms used to refer to different concepts. Moreover, terms and schemes sometimes overlap or only partially capture the complexity of the phenomenon of innovation. In this section, we present a metatypology, or typology of typologies, that seeks to provide some structure to the existing typologies in the literature. In doing so, we follow three criteria. First, the typology must be exhaustive and comprehensively capture the full extent of a phenomenon. Second, the typological units or categories of the typology should be mutually exclusive, thus avoiding redundancies and overlap. Finally, the typology should be parsimonious.

Taking into account these three hallmarks, we synthesize the various schemas discussed in the section above into a single typology laid out in Table 1. We identify two key dimensions that underpin all the various typologies mentioned in the literature. The first dimension classifies innovations based on attributes (i.e., what they are) versus their effect (i.e., what they do). The second dimension classifies innovations based on their locus of novelty: the novelty of the concept itself, or the novelty of the innovation in relation to the customer or the company that introduces or adopts it. Accordingly, we classify

product/service/process innovation, technological breakthrough/platform innovation, component innovation, architectural/design innovation, and business model innovation all as types of innovation that emphasize the innovation's attributes (i.e., what it is) and whose locus of novelty lies in the concept behind the innovation. Similarly, we classify market breakthroughs and disruptive innovations as types of innovation that emphasize the innovation's attributes (i.e., what it is) and the novelty of the innovation in relation to the customer. Likewise, we classify new to the firm innovation, organizational innovation, administrative innovation, and management innovation as types of innovation that emphasize the innovation's attributes (i.e., what it is) and the novelty of the innovation in relation to the company. Drastic innovation and revolutionary innovation we classify as being types of innovations that emphasize the innovation's effects (i.e., what it does) and whose locus of novelty lies in the concept behind the innovation. In contrast, we classify discontinuous innovation and disruptive innovation as types of innovation that emphasize the innovation's effects (i.e., what it does) and the novelty of the innovation in relation to the customer. And finally, we classify competence-destroying innovation, competence-enhancing innovation, and disruptive innovation as types of innovation that emphasize the innovation's effects (i.e., what it does) and the novelty of the innovation in relation to the company.

WHAT ARE THE IMPLICATIONS OF THE TYPOLOGY WE PROPOSE?

The metatypology in Table 1 has several implications for research and practice. We discuss each of these in turn.

Implications for research. The metatypology we propose in Table 1 helps to reduce some of the confusion and complexity in the literature on the types of innovation. While the literature suggests many different dimensions underlie innovation, the typology shows that, in fact, only two major dimensions underlie most types of innovation. In identifying only two underlying dimensions, the typology meets the important condition of

parsimony in a classification scheme. Further, by capturing most major types of innovation, the typology is also exhaustive and comprehensive. Third, the typology ensures that the categories it suggests are mutually exclusive, thus avoiding redundancies and overlap.

By meeting the major conditions of a good typology, Table 1 provides the basis for a rigorous approach to the study of innovations. Specifically, it forms the basis for further research that can help better circumscribe the rich and diverse phenomenon of innovation, and its antecedents and consequences. Most importantly, it furthers the task of good theory in the area, namely, to be able to explain and predict aspects of the phenomena in a parsimonious and logically rigorous way.

Implications for practice. The typology in Table 1 provides at least three major benefits for managers. Specifically, it helps managers make better innovation decisions in the areas of (i) portfolio assessment, (ii) resource allocation (time, people, money), and (iii) portfolio management. A key issue for managers is to be able to assess in real time the extent to which their portfolio of existing products as well as those in the pipeline are complete and sufficient given their firms' short and long term objectives. The typology in Table 1 enables managers to keep a track of the various types of innovations they have planned and introduced in markets over time. This in turn helps them assess any imbalances in the portfolio. Any imbalances in the portfolio would immediately suggest a reallocation of resources devoted to the development and support of innovations. Such imbalances would also suggest means to systematically identify and generate new innovations by, for instance, seeking novelty in innovations based on their relationship with concepts, customers, or the company itself.

innovation metrics

David Reibstein and Venkatesh Shankar

INTRODUCTION

Innovation is essential for the future of any firm. Philips, for example, in 2008 had 58% of their sales from newly introduced products – products introduced within the last year (for Business to Consumer [B2C] products) or three years (for Business to Business [B2B] products) (Philips, 2009). This is an amazingly high number for a large established company such as Philips. Nonetheless, it is essential that the flow of new products be constant to keep the firm vibrant and reinvent itself. To achieve these objectives, firms make significant investments in innovation. To manage and track these investments, they gather numerous measures and monitor their progress. Many times, these metrics are used to diagnose the innovation investment performance. There are various stages of innovation development, and not surprisingly there are measures at each of the different stages (see THE STAGE-GATE IDEA TO LAUNCH SYSTEM). We will review the innovation measures that are regularly collected and used to assess the innovation process. Ideally, these measures should provide strategic direction for the innovation activities and guide future resource allocation decisions. They should also help in assessing the effectiveness of innovation spending, and, in many cases, help make managers accountable.

STAGES OF INNOVATION DEVELOPMENT

Firms go through several stages of innovation development, starting from the inception of an idea to the launch of a product or service. Firms need to assess performance at each of these stages. To facilitate such a continual assessment, firms can benefit from the use of an “innovation dashboard” that offers a snapshot of performance at each major innovation development stage—from the inputs, through the development process, all the way to outputs such as introduction into the marketplace (see Table 1). In the section that follows, we will review the measures commonly used to assess progress at each stage.

Input metrics. These are measures that capture all early stage investments and resources required during the inception of the innovation. It is essential for a firm to assess whether there is a sufficient number of new product ideas (pipeline of ideas) and whether a sufficient amount is being budgeted for future potential. It would be possible to assess where the new product ideas are coming from and if there is a sufficient flow of innovations to ensure future viability for the firm. It is also necessary to keep track of the resources that are required at the early stage. There needs to be a steady flow of innovations at various stages of development (see PORTFOLIO MANAGEMENT). If the flow of innovations is out of balance, this will be reflected in the financial performance of the firm. If there is an imbalance in projects such that most investments are skewed toward early stage innovations, it could drain the resources of the firm, without letting it reap the rewards of their introductions to the market. Further, there may not be enough resources to bring other projects to completion. At the input stage, there tends to be measures of the number of projects under development and the corresponding resources they require.

Process effectiveness metrics. These measures relate to the effectiveness of the research and development process. It is natural for many projects to be initiated, but for some to be terminated at different points during the development process. As firms develop new innovation projects, they continually undertake market assessments for those projects. If a large percentage of the projects make it through to completion, then the idea generation process is probably not producing concepts that stretch the firm very much. Obviously, the other extreme is probably even more troublesome. It would mean that many resources are being spent on projects that never make it to the market. One of the key measures is the number of projects reaching the different stages (steps of development) on time. Firms typically follow a timetable of stages for each innovation project. If an insufficient number of innovations are meeting their scheduled gates on time, it would suggest that either the plans or the forecasts need to be modified. Alternatively, it could

Table 1 Innovation dashboard.

| <i>Inputs</i> | <i>Process effectiveness</i> | <i>Performance outcomes</i> |
|---|---|---|
| 1. R&D spending (percent of sales) | 1. Development activities <ul style="list-style-type: none">– Percentage hitting gates on time– Percentage meeting quality guidelines | 1. Percentage of sales from new products in past N years |
| 2. Human resources devoted to innovation <ul style="list-style-type: none">– Number of personnel on innovation projects– Payroll costs of innovation employees | 2. Patenting activity <ul style="list-style-type: none">– Number filed– Number commercialized– Percentage of new ideas covered by patents | 2. Successful new products (number and ratio of new products meeting financial goals) |
| 3. Number of new ideas/concepts in the pipeline | 3. Budget versus actual <ul style="list-style-type: none">– Time– Cost/investment | 3. Revenue growth |
| 4. Number of R&D projects in active development | 4. Number of new products introduced (firm innovativeness) | 4. Return on investment in innovation |
| 5. Percent of ideas/concepts from outside the firm | 5. Average time to market | 5. Percentage of profits from new customers (or occasions) |
| | 6. Percentage of projects that are major improvements | 6. Percentage of profits from new categories |
| | 7. Percentage of projects resulting in new product launch | 7. Average time to break-even |
| | | 8. Change in Customer satisfaction |
| | | 9. Profit growth due to new products/services |
| | | 10. Percentage of profits from new products in a given period |
| | | 11. Change in NPV of portfolio |
| | | 12. Percentage of growth target attributable to change in product portfolio |
| | | 13. Change in marketvalue or shareholder returns due to new products |

mean the planning is fine but the development is ineffective and changes will have to be made in the development process.

In developing their innovations, firms need to be wary of protecting their intellectual properties so that they have the opportunity to fully capitalize on the resources invested. As part of the development process, firms need to ensure that relevant patents are filed and obtained in a timely manner (*see* INTELLECTUAL PROPERTY RIGHTS).

Many firms assess their innovation progress through the “time to market” metric. It has been argued that much of the troubles US firms have experienced with regard to innovation relates to moving projects through development

and bringing them to the market in a timely manner. Being late to the market has its costs, so time to market is a critical measure of the innovation process.

Firms also need to have a balance of both big ideas and small ideas. The bolder innovations tend to be more costly to both develop and launch since there is minimal internal experience within the organization. Yet, modest changes to the existing portfolio can only grow the firm so much.

Performance outcome metrics. The vast majority of the measures used to assess innovation relates to the outcome stage. This is somewhat unfortunate because such measures can be tracked only

after the innovation is complete, not affording the opportunity to adjust the process of innovation. Yet, if the overall performance of the innovations is poor, it does imply the need to modify the process, even if it does not indicate how the process should be adjusted. The majority of measures are at this stage as these tend to be more objective than measures at earlier stages. This is also the case that the major objective is financial performance.

Perhaps, the most commonly used measure is the percentage of sales from new products over the past few years. This measure indicates how much innovations contribute to the firm's top line. Of course, an important question relating to this measure is: what constitutes a "new product?" Making slight modifications to existing products and then claiming that the innovation process is working misses the purpose of this measure and does not give a true sense of whether the innovation development process is oriented toward the future of the firm. Firms seek incremental new sales from the new products rather than merely obtain sales that replace sales from former products.

A measure which does capture whether the innovation development process is working is the success ratio of the new products. Again, this is a measure on which 100% is not the desired goal as it would indicate that the firm is not reaching far enough with the innovation efforts; yet, most companies strive to have this number be as large as is possible. The big question is what constitutes "success." This success ratio could be increased merely by setting a lower success hurdle, which would defeat the purpose of this measure.

Revenue growth, as a measure, is also frequently used by firms. Unfortunately, this measure might be achieved because of factors other than innovation, such as marketing efforts or the size of the chosen markets. Similarly, return on investments in innovations, a financial measure, is also flawed because it might reflect the impact of the level and effectiveness of the marketing efforts and not the innovation.

Perhaps, a more reasonable outcome measure is the percentage of profits from new products or profit growth from new products. This is less commonly used than percentage of sales because new products seldom make money in their early

years. This measure would not reflect the true potential of new products. Hence, some companies have sought to use a measure of the percent of time to breakeven. While this measure does not reflect the innovation development process, it indicates the speed at which innovation projects get accepted in the marketplace and provide a return to the company.

Another commonly used outcome measure is overall growth in firm profits. Because the overall profit growth of the firm could be attributed to the growth decline from existing products, it would make sense for firms to focus on revenue and profit growth that are directly attributable to new products.

The most commonly used customer-related measure of innovation is customer satisfaction. This is a powerful measure for several reasons. First, it indicates whether the development process has yielded a product or service that the customer wants. It indicates the extent to which the firm has listened to the customer and responded to customer needs (*see VOICE OF THE CUSTOMER*). Second, it indicates whether further innovation development is needed. If a sufficient number of customers are not fully satisfied, there is opportunity to grow if further development is done on the product or service. More importantly, unlike other measures which indicate current market place performance, customer satisfaction is believed to be a good indicator of future performance. Customers who are satisfied are likely to be future customers as well as advocates or evangelists to others about the quality of the firm's new offering. The Net Promoter Score (NPS) is a variant of satisfaction which companies such as General Electric have adopted (Reichheld, 2006). It is based on the concept that the future performance of a product or service is driven by the number of customers who are highly satisfied and are likely to be "promoters" of the product relative to those that are less satisfied and might be "detractors." Thus, the NPS is measured as the difference between the percentage of promoters and the percentage of detractors (Reichheld, 2006).

At a firm level, an important innovation metric is firm innovativeness – the number of new offerings introduced annually by the firm. While customer satisfaction or NPS might be good

potential indicators of future success of a particular innovation, at a firm level, customer satisfaction is not significantly related to firm innovativeness (Dotzel, Shankar, and Berry, 2010). However, both innovativeness and customer satisfaction are positively related to firm value as measured by Tobin's Q (Dotzel, Shankar, and Berry, 2010). Thus, firm innovativeness may be a leading indicator of a firm's future success.

METRICS USAGE

All of the metrics shown in Table 1 are used, but they are not all used with the same frequency. Most firms use a stage-gate process to monitor the progress of their innovation development. Some firms use growth rate as the best proxy for assessing whether their innovation process is working. Among outcome measures, customer satisfaction is used by 44% of the firms as their primary measure of innovation success according to Boston Consulting Group (2009).

Griffin and Page (1993) conducted one of the early studies examining what measures companies were using to assess their innovation process. They found that 86% of the firms in their study use customer and financial measures and few used process measures. We reexamined this issue nearly two decades later as innovation has grown in importance. We studied the importance of innovation, the metrics used, and the perception of outcomes. With the cooperation of McKinsey & Company, we used the McKinsey Quarterly database, which consists of 18 668 executives, the majority of whom are either C-level or other senior executives. Companies represented in our sample range from quite small with revenues less

Table 2 Strategic importance of innovation^a.

| | <i>Number of metrics used</i> |
|----------------------------|-------------------------------|
| • Top strategic priority | 9.5 |
| • Second of third priority | 8.0 |
| • Not among top 3 | 6.8 |

^aCompanies use an average of 7.9 out of possible 26 metrics

than \$1 million to firms with revenues in excess of \$30 billion.

Not surprisingly, we found that innovation remains a top priority for the vast majority of firms. Firms use a myriad of metrics primarily to provide strategic direction for their innovation activities, guide resource allocations, and to improve innovation performance.

On average, companies use 7.9 different measures to assess their innovation process. The more strategically important they believed innovation was to the firm, the more measures they used (see Table 2).

Without question, the most commonly used measures were outcome measures rather than process or input measures (see Table 3).

The most widely used metric under input measure was number of new ideas/concepts in the new product pipeline; for process effectiveness it was the number of new products launched; and for performance outcome metric it was revenue growth.

Firms in the survey claimed that the primary use of their innovation metrics was to (in order)

Table 3 The most used measures (proportion of sample using the metric).

| <i>Inputs</i> | <i>Process effectiveness</i> | <i>Performance outcomes</i> |
|--|-------------------------------------|--|
| • Number of new ideas/concepts in the pipeline | • Number of products launched (46%) | • Revenue growth (60%) • Customer satisfaction (48%) • Return on investment in innovation (48%) • Profit growth (45%) • Percent of sales from new product in past <i>N</i> years (44%) |

Only metrics used by at least 40% of sample are shown

- assess the effectiveness of innovation spending,
- effectively allocate resources,
- improve people's accountability,
- improve overall innovation performance,
- assess progress against overall goals, and
- communicate effectively to the investment community.

Interestingly, however, we found that only 19% felt their organization's innovation metrics were effectively aligned with individual performance incentives. While the desire is to use these metrics for the above purposes, it is unclear whether the metrics used today fully accomplish any of the above objectives.

CONCLUSIONS

Firms use a large number of innovation metrics. These metrics cut across the spectrum of the innovation process but are highly skewed toward outcome measures. There clearly is no single "silver bullet" measure. While

most organizations find innovation extremely important and measure it vigorously, they are still not adequately satisfied with their innovation measurement. Clearly, more work is needed in this area for us to move forward.

the Stage-Gate idea to launch system¹

Robert G. Cooper

AN IDEA-TO-LAUNCH ROADMAP

New products are critical to the survival and prosperity of the modern corporation. But product innovation is not so easy: new products fail at an alarming rate (about 1 in 10 new-product concepts succeeds); 44% of new-product projects fail to meet their profit objectives; and 49% are launched late to market (Adams and Boike, 2004; Cooper, 2001; Cooper, Edgett, and Kleinschmidt, 2003; Griffin, 1997).

A *Stage-Gate*[®] system is one solution that many leading companies have adopted to drive new-product projects to market quickly and effectively². Almost every top-performing company has implemented a stage-and-gate system to drive their new-product projects through to commercialization, according to an APQC (American Productivity and Quality Center) benchmarking study into product innovation (Cooper, Edgett, and Kleinschmidt, 2003, 2005). PDMA (Product Development and Management Association) management best practices studies show similar adoption rates (Adams and Boike, 2004; Griffin, 1997).

A *Stage-Gate*[®] new-product process is simply a “playbook,” “game plan,” or road map to guide new-product projects from idea to launch. Here, we look at what a *Stage-Gate*[®] system is, and then at 10 best practices that top-performing businesses have built into their stage-and-gate methodologies. We also provide an outline of the *Stage-Gate*[®] system via a walk-through process.

THE STRUCTURE OF STAGE-GATE[®]

The *Stage-Gate*[®] method breaks the product innovation process into a predetermined set of stages, each stage consisting of a set of prescribed, cross-functional, and parallel activities (see Figure 1). Gates are the entrance to each stage, and serve as quality-control and Go/Kill check points. This stage-and-gate format leads to the name “*Stage-Gate*[®]” process.

The *Stage-Gate*[®] method is based on the experiences and observations of a large number of managers and firms from research by the

author and others in the field. Since *Stage-Gate*[®] first appeared in print, it has been implemented in hundreds of leading firms worldwide, many of which have provided an excellent setting to further improve the process (Cooper, 2008).

The stages. Stages are where the project team members execute key tasks to gather information needed to advance the project to the next gate. And there is a *fairly standard* or *prescribed list of tasks* for each stage. The specified tasks answer the following questions:

- What does the management need to know at the end of this stage to make an informed decision to move forward?
- What actions are therefore required to get this information?

For example, in Stage 2, Build the Business Case, a number of key tasks are required to deliver a business case, such as undertaking Voice-of-Customer research (see VOICE OF THE CUSTOMER), doing a competitive analysis (see COMPETITIVE ADVANTAGE), defining the product, and doing a source-of-supply assessment.

Stages are cross functional: There is no R&D or marketing stage, and handoffs from one department to another are not permitted. Rather, *Stage-Gate*[®] is an *integrated business process*, with each stage consisting of a set of parallel tasks undertaken by *people from different functional areas* within the firm, working together as a team and led by a project team leader (see INTEGRATED PRODUCT DEVELOPMENT).

To manage risk via a *Stage-Gate*[®] method, the parallel tasks in each stage are designed to gather vital information – technical, market, financial, operations – to reduce *both* the *technical* and *business risks* of the project. Each stage costs more than the preceding one, so that the process is based on incremental commitments. As uncertainties decrease, expenditures are allowed to mount, and risk is managed.

The flow of the typical *Stage-Gate*[®] model is shown in Figure 1:

1. *Discovery*: prework designed to discover opportunities and to generate new-product ideas (see also IDEA MANAGEMENT).

2 the Stage-Gate idea to launch system

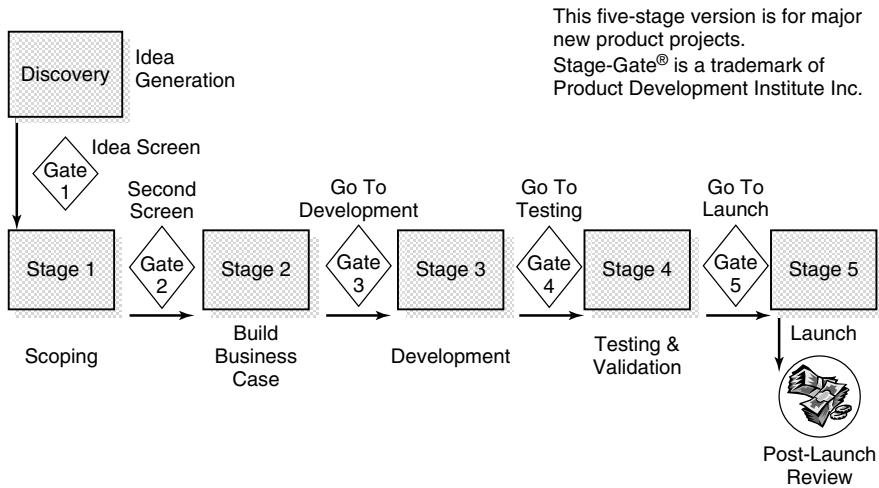

Figure 1 The five-stage Stage-Gate® process is used by many businesses to drive new products from idea to launch.

2. *Scoping*: a quick, preliminary investigation, and scoping of the project. This stage provides inexpensive information – based largely on desk research – to enable the list of projects to be narrowed before Stage 2.
3. *Build the business case*: a much more detailed investigation involving primary research – both market and technical – leading to a *business case*. This is where the bulk of the vital homework is done, which results in a business case: the product definition, the project justification, and a project plan (see CONCEPT TESTING).
4. *Development*: the detailed design and development of the new product, along with some product testing work (see PRODUCT TESTING). The deliverable at the end of Stage 3 is an alpha-tested or lab-tested product. Full production and market launch plans are also developed in this potentially lengthy stage.
5. *Testing and validation*: tests or trials in the marketplace, lab, and plant to validate the proposed new product, and its marketing and production or operations. Tasks include field trials or beta tests; test market or trial sell; and operations trials (see PRETEST MARKET MODELS).
6. *Launch*: commercialization – beginning of full operations or production, marketing,

and selling. Here the market launch, operations, distribution, and postlaunch plans are executed (see LAUNCH STRATEGIES).

The gates. Preceding each stage is an entry gate or a Go/Kill decision point. Effective gates are central to the success of a fast-paced, new-product process:

- Gates serve as quality-control checkpoints, ensuring that the project is executed properly.
- Gates also serve as Go/Kill and prioritization decisions points: mediocre projects are culled out at each successive gate.
- Finally, gates are where the action plan for the next stage is agreed, and the resources needed to execute the plan are committed.

Gate meetings are usually staffed by senior managers from different functions – the gate-keepers – who own the resources required by the project team for the next stage.

Gates have a common format:

1. *A set of required deliverables*: what the project team must bring to the gate decision point. These deliverables are visible, are based on a standard menu for each gate,

and are decided at the output of the previous gate. Management's expectations for project teams are thus made very clear.

2. *Criteria:* the project is judged against these to make the Go/Kill and prioritization decisions.
3. *Defined outputs:* for example, a decision (*Go, Kill, Hold or Recycle*), an approved action plan for the next stage including resource requirements, and a list of deliverables for the next gate.

Types of gate criteria. Each gate has its own set of criteria for use by the gatekeepers:

- *Readiness check:* These are Yes/No questions that check whether the key tasks have been completed, and that all deliverables are in place for that gate. A "No" signals a recycle to the previous stage because the project is *not ready* to move on.
- *Must meet:* These are Yes/No or "knock-out" questions that include the minimum business criteria that a project must meet to move forward. A single consensus "No" signals a Kill decision.
- *Should meet:* These are highly desirable project characteristics that are used to distinguish between superb projects and the minimally acceptable ones. These are typically in a scorecard format (see PORTFOLIO MANAGEMENT) (Cooper, Edgett, and Kleinschmidt, 2002).

Building in best practices. A number of best practices are built into the *Stage-Gate*[®] idea-to-launch system to yield superlative results (see SUCCESS FACTORS FOR NEW-PRODUCT DEVELOPMENT):

Tough gates with teeth for sharper focus, better project prioritization. Most businesses' new-product efforts suffer from a lack of focus: too many projects, and not enough resources to execute them well (Cooper, 2005; Cooper, Edgett, and Kleinschmidt, 2002). Adequate resources is a principal driver of businesses' new-product performance; but a lack of resources plagues too many development efforts (Cooper, Edgett, and Kleinschmidt, 2003).

the Stage-Gate idea to launch system 3

The need is for a *new-product funnel* (rather than *tunnel*) that builds in tough Go/Kill decision-points in the form of gates; poor projects are weeded out and more focus is the result. The expectation is that a significant percentage of projects will be killed at each gate, especially at the earlier gates (Gates 1-3 in Figure 1). The gates thus become the *quality-control check points* in the new-product process, checking the quality, merit, and progress of the project.

Products with competitive advantage – differentiated products, unique benefits, superior value for the customer. Product superiority is one key to new-product success, yet all too often, when applying a new-product process, there is no attempt to seek truly superior products (see also COMPETITIVE ADVANTAGE; VALUE PROPOSITION). An effective *Stage-Gate*[®] system builds in the quest for product advantage:

- Some of the criteria at every gate focus on product superiority. Questions such as "Does the product have at least one element of competitive advantage?" become vital questions to rate projects.
- Customer-related tasks designed to deliver product superiority are included in each stage of the process. Examples are given in the next section.
- Project teams are required to deliver evidence of product superiority to gate reviews.

A strong market orientation with Voice-of-Customer inputs throughout. A strong market orientation – executing the key marketing activities in a quality fashion – must be built into the new-product process. Six best-practice marketing actions that are incorporated into the stages of a robust *Stage-Gate*[®] system include the following:

- customer-focused ideation to gain insights into customer problems;
- preliminary market assessment in the very early phases of the new product project;
- Voice-of-Customer research to identify unmet or unarticulated needs;

4 the Stage-Gate idea to launch system

- competitive product analysis to determine their strategy and how to surpass them;
- value-in-use analysis to gauge the economic value of the product to the customer;
- concept tests, preference tests, and trial sells to validate the product and the project.

Front-end loading projects leading to sharp, early, and stable product definition. New-product success or failure is largely decided in the first third of the project – in those crucial steps and tasks that precede the actual development of the product. The up-front homework defines the product and builds the business case for development. The ideal new-product process ensures that these early stages are carried out and that the product is fully defined before the project is allowed to become a full development project.

The need for solid up-front homework parallels the case for a strong market orientation. Top performer businesses ensure that the new-product process includes solid homework (Stages 1 and 2 in Figure 1) and stable, fact-based product definition. For example, they build in a product-definition check-point at Gate 3; and they halt projects if the homework and product definition are not in place.

A fast-paced game plan via parallel processing and simultaneous execution.

New-product teams face a dilemma. They are urged by senior management to compress the cycle time but also to cut down the failure rate – do it right! (*see also* ACCELERATED PRODUCT DEVELOPMENT; INTEGRATED PRODUCT DEVELOPMENT) *Simultaneous execution* is one solution to the need for a complete and quality process, yet a process that meets time pressures (Cooper and Edgett, 2005; Morgan, 2005). Traditionally, new-product projects have been managed via a *series approach*: one task strung out after another, in sequence. Phrases such as “hand off” or even “throwing it over the wall” are common in this *relay-race approach*.

In contrast, with simultaneous execution, many activities are undertaken *in parallel* and *concurrently* rather than in series. The process is far more intense than a relay race, with more work getting done in an elapsed time period.

Moreover, there is less chance of a task being skipped because of lack of time, as each task is done in parallel, not in series, and hence does not extend the critical path.

A true cross-functional team approach.

The multifunctional nature of innovation coupled with the desire for simultaneous execution means that a *cross-functional team approach* is mandatory (*see also* CROSS-FUNCTIONAL TEAM). The essential ingredients of this approach are

- a cross-functional project with committed team players from the different functional areas;
- a defined team leader, driving the entire project beginning to end, and with formal authority (coopting authority from the functional heads);
- a fluid team structure, with new members being brought in or dropped as work requirements demand;
- only a small core group of responsible and committed team players from beginning to end;
- most important, a team that is accountable for the entire project’s end results (not just responsible for one part of the project).

Adaptable and agile via spiral development.

Spiral development is one way that fast-paced companies cope with changing or fluid information as the project proceeds (Cooper and Edgett, 2005). Often, a project team charges into development using a product definition based on information that was right at the time. But it was not right, or customer requirements changed, and when the product is ready for testing or market launch (Stage 4 or 5 in Figure 1), it is discovered that the product is not quite right. This *traditional linear approach* means that the team must then recycle back to the development stage, and make the necessary changes to the product and its design.

By contrast, smart project teams practice *spiral development* and adapt and adjust their project over time, as in Figure 2. Like the “linear team” above, they do their front-end homework (Voice-of-Customer work, competitive analysis,

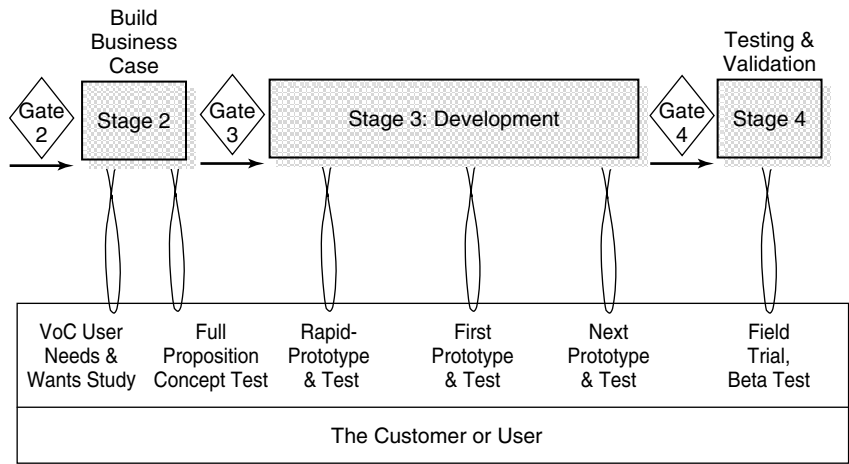

Figure 2 Stage-Gate® builds in adaptability and agility via a series of “build–test–feedback–revise” iterations or loops.

and concept testing) and define the product based on best-available information. But quickly, the “adaptive-spiral team” creates the first version of the product (often a virtual one) and tests it with the customer, seeking immediate feedback. The team uses this feedback to produce the next, more complete version of the product – a working model or protocept. In this way, these fast-paced teams remove unnecessary rework and quickly move to the finalized product by undertaking a series of these iterative steps or loops: *build, test, obtain feedback, and revise*.

Risk-adjusted and scalable. When originally conceived, companies typically designed a *single* stage-and-gate process – “one size fits all projects,” usually designed for *the most complex development projects* (Cooper, 2008). Most projects, however, were much simpler – modifications and improvements – and so teams simply circumvented the “large process.” The dilemma was that these small projects consumed the bulk of development resources, and so the firm ended up having most of the funds spent on projects that were “outside the system.”

Now there are streamlined versions of Stage-Gate®, including Lite and XPress, designed to handle lower risk, simpler projects. For example, in the model in Figure 3, all proposed development projects enter Gate 1 on the left

for an initial screen and routing decision, and depending on the risk level, follow different versions of Stage-Gate®. Additionally, some companies engaged in very innovative development projects – for example, advanced technology projects – have adopted quite different development processes to handle these high-risk, longer-term, and highly uncertain projects (Cooper, 2006).

A lean, efficient process with time wasters removed. The idea-to-launch system must be built for speed. This means eliminating all the time wasters and work that add no value in the current new-product process. Using principles borrowed from lean manufacturing, management undertakes “value stream analysis,” reviewing the development process from end to end, scrutinizing every required procedure, meeting, or paperwork that must be completed (Kennedy, 2003), and removing any work that does not add value. The end result is that current versions of Stage-Gate® are much leaner and more efficient than previous systems.

Performance metrics in place. The idea-to-launch system should feature solid performance metrics, so that senior management can assess how well the development process is working and hold project teams accountable for results. For individual new-product projects,

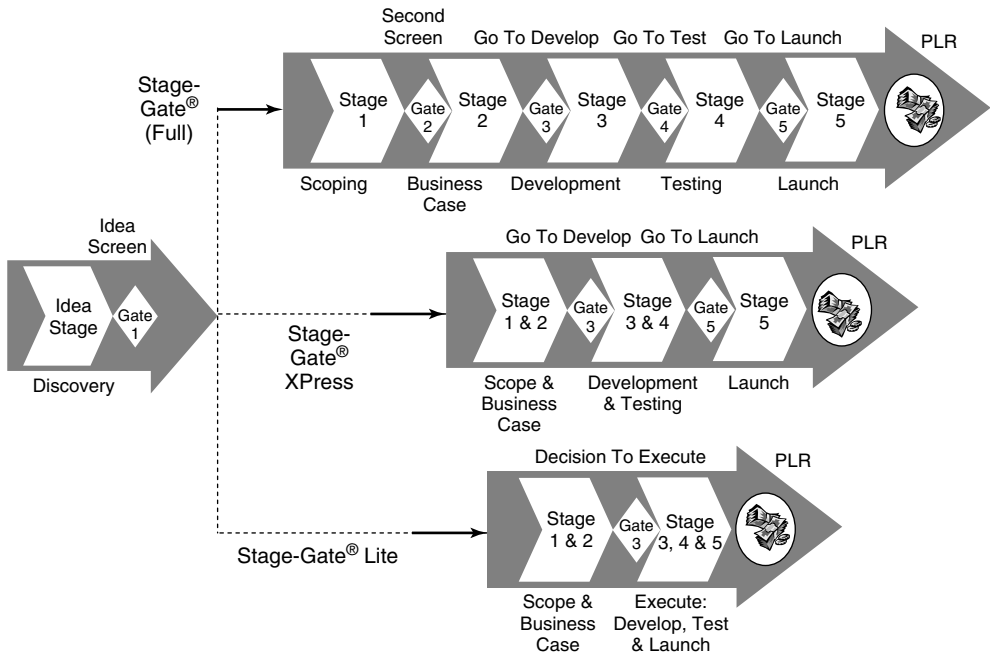

Figure 3 Stage-Gate® XPress and Lite are used for lower-risk projects. Major new-product projects go through the full five-stage process (top). Moderate-risk projects, including extensions, modification, and improvements, use the XPress version (middle). Sales-force requests (very minor changes) use the Lite process (bottom).

success metrics often include (see also INNOVATION METRICS) the following:

- first-year sales (versus the sales forecast in the business case at Gate 3);
- product profitability versus that forecast in the business case;
- on-time performance (actual versus promised launch date) (Cooper, Edgett, and Kleinschmidt, (2003, 2005)).

Top-performing companies also build in a *postlaunch review* 12–18 months after launch, where these metrics are used to gauge the *ultimate success* of the project. Here the project's actual results are assessed versus those results promised when the project was approved at Gate 3. Additionally, sales, profits, and on-time performance results for individual projects can be aggregated or averaged to yield performance metrics for the business's entire new product effort.

A WALK-THROUGH OF THE STAGE-GATE® SYSTEM

Here is a more detailed look at the *Stage-Gate®* system – of what is involved at each stage and gate in the model outlined in Figure 1 (Cooper, 2001, 2005, 2008).

Discovery stage. Ideas are the vital feedstock to the process. Many companies consider ideation so important that they handle this as a formal stage in the process, called *Discovery*, with many activities built into this stage, such as (Cooper and Edgett, 2008)

- undertaking fundamental technical research, seeking new technological possibilities (Cooper, 2006);
- doing Voice-of-Customer research to uncover unmet, unspoken needs (includes ethnography, working with lead users, and depth interview with customers);

- competitive analysis and reverse brainstorming competitive products;
- installing an idea suggestion scheme to solicit ideas from the company's own employees;
- using strategic planning to uncover disruptions, gaps, and opportunities;
- open innovation – welcoming ideas and solutions from outside the company (see OPEN INNOVATION).

Gate 1: Idea Screen. Idea screening is the first decision to commit resources to the project: If the decision is Go, the project moves into the scoping or preliminary investigation stage. Gate 1 signals a preliminary but tentative commitment to the project, and is a gentle screen that amounts to subjecting the project to a handful of key must-meet and should-meet criteria. Financial criteria are typically not part of this first screen, since relatively little reliable financial data are available here.

Stage 1: Scoping. This first and inexpensive homework stage determines the project's technical and marketplace merits: a quick scoping of the project, involving only desk research (no primary research). Stage 1 is often done in less than one calendar month's elapsed time, and 5–10 person-days' work effort. The key tasks include

- a *preliminary market assessment* whose purpose is to determine market size, market potential, and likely market acceptance, and to begin to shape the product concept;
- a *preliminary technical assessment* whose purpose is to assess development and manufacturing routes (or source of supply), technical and operations feasibility, time and cost to execute, and technical, legal, and regulatory risks.

Stage 1 thus provides for the gathering of both market and technical information – inexpensively and quickly – to enable a cursory financial and business analysis as input to Gate 2.

Gate 2: Second Screen. The project next proceeds to more rigorous screen at Gate 2, where the project is reevaluated with new information obtained in Stage 1. If the decision is Go, the

the Stage-Gate idea to launch system 7

project moves into a heavier spending stage. A checklist and scoring model facilitate this gate decision.

Stage 2: Build the Business Case. Stage 2 is a detailed investigation stage, which defines the product and verifies the attractiveness of the project prior to heavy spending. It is also the *critical homework* stage, the one found to be so often weakly handled.

Stage 2 sees Voice-of-Customer research undertaken to exactly determine the customer's needs, wants, and preferences. Competitive analysis is also a part of this stage. Another market activity is concept testing where potential customers' reactions to the concept are gauged.

The detailed *technical appraisal* at Stage 2 focuses on the technical feasibility of the project. Here, customer needs are translated into a technically and economically feasible solution on paper – preliminary design or laboratory work, but not a full development effort. An operations appraisal is undertaken, where issues of manufacturability, source of supply, costs, and investment required are investigated. And detailed legal, patent, and regulatory assessment work is done to remove risks and map out the required actions (see also INTELLECTUAL PROPERTY RIGHTS).

Finally, a detailed *business and financial analysis* is conducted, typically a net-present-value calculation, complete with sensitivity analysis to consider possible risks. The result of Stage 2 is a *business case* for the project: the *product definition* is agreed upon; and a thorough *project justification* and *detailed project plan* are developed.

Gate 3: Go to Development. This is the final gate prior to the development stage, the last point at which the project can be killed before entering heavy spending. Once past Gate 3, financial commitments are substantial, thus Gate 3 is usually staffed by senior management.

Gate 3 subjects the project to a rigorous set of readiness-check, must-meet, and should-meet criteria. And because a heavy spending commitment is the outcome of a Go decision, the results of the financial analysis are an important part of this screen.

Stage 3: Development. Stage 3 sees the implementation of the development plan and the

8 the Stage-Gate idea to launch system

physical development of the product. Lab tests, in-house tests, or alpha tests ensure that the product meets requirements under controlled conditions. Also, the operations or source-of-supply process is mapped out. Extensive in-house tests, alpha tests, or lab tests usually take place in this stage as well. The deliverable at the end of Stage 3 is a lab-tested or alpha prototype of the product.

The emphasis in Stage 3 is on technical work. But marketing and operations activities also proceed in parallel. For example, market-analysis and customer-feedback work continue concurrently with the technical development, with constant customer feedback sought on the product as it takes shape via *spiral development*. Meanwhile, detailed test plans, market launch plans, and production or operations plans, including operations facilities requirements, are developed. An updated financial analysis is prepared, while regulatory, legal, and patent issues are resolved.

Gate 4: Go to Testing. This postdevelopment gate is a check on the progress and the continued attractiveness of the project. Development work is reviewed, ensuring that the developed product is indeed consistent with the original definition specified at Gate 3. This gate also revisits the project's economics via a revised financial analysis. The validation plans for the next stage are approved, and the detailed market launch and operations plans are reviewed for future execution.

Stage 4: Testing and Validation. This stage validates the viability of the project: the product, its production process, customer acceptance, and its economics. The key tasks are

- *In-house product tests:* extended lab tests or alpha tests to check on product quality and product performance under controlled or lab conditions.
- *User, preference, or field trials of the product:* to verify that the product functions under actual use conditions, and also to measure purchase intent.
- *Trial, limited, or pilot operations:* to test, debug, and prove the operations process, and to determine more precise costs and throughputs.

- *Pretest market, test market, or trial sell:* to gauge customer reaction, measure the effectiveness of the launch plan, and determine expected market share and revenues.

Gate 5: Go to Launch. This final gate opens the door to full commercialization: market launch, and operations start-up. Criteria for passing the gate focus largely on the expected financial return, the project's readiness for launch, and the appropriateness of the launch and operations start-up plans.

Stage 5: Launch. This final stage involves implementation of both the market launch plan and the operations plan. Equipment is acquired, installed, and commissioned (although sometimes this is done earlier in Stage 4, as part of the Stage 4 operations trials); the logistics pipeline is filled; and selling begins.

Post-Launch Review. Two Post-Launch Reviews are typical. The first, an interim review, occurs about two to four months after launch when initial commercial results are available. Here a *retrospective analysis* is done, which assesses the project's strengths and weaknesses, and identifies what can be learned from the project. This task builds in *continuous improvement*.

The final review is held once the project's commercial results are known, typically 12–18 months after launch. Here, the project and product's performance is reviewed: The latest data on the revenues, costs, expenditures, profits, and timing are compared to projections made at Gates 3 and 5 to gauge performance. This final review marks the end of the project.

CONCLUSION

Product innovation is perhaps the most important endeavor of the modern corporation. Without a systematic new-product process, however, often product development suffers. The *Stage-Gate*® system is an enabler or guide, building in best practices and ensuring that key tasks and decisions are undertaken better and faster. But *Stage-Gate*® is considerably more complex than the simple diagram in Figure 1

suggests; there are many intricacies in the details – both the “what’s” and the “how to’s.” And implementing the process is also a major challenge. Many leading companies, however, have adopted a world-class idea-to-launch *Stage-Gate*[®] system, and the results have been positive: better, faster, and more profitable new-product developments.

diffusion of innovation

Deepa Chandrasekaran and Gerard J. Tellis

DEFINITIONS

An innovation is an idea, practice, or object that is perceived as being new by an individual or other unit of adoption (Rogers, 1995). There are several definitions of “diffusion.” Some scholars define *diffusion* as a special type of communication where the message refers to an innovation (Rogers, 1995; Mahajan, Muller, and Wind, 2000). In this sense, diffusion refers to the process by which an innovation is communicated through certain channels over time among the members of a social system. Other scholars differentiate the *phenomenon*, diffusion, from its *drivers*, such as product’s price, advertising, or word-of-mouth communication. In this sense, diffusion refers to the spread of an innovation across social groups or markets over time (Stoneman, 2002; Chandrasekaran and Tellis, 2007).

SHAPE OF THE DIFFUSION CURVE

Numerous studies in a variety of disciplines suggest that the typical plot of cumulative adoptions of new products or technologies over time is an S-shaped curve (e.g., Mahajan, Muller, and Wind, 2000, *see also* TECHNOLOGY S-CURVE). The Bass diffusion model (Bass, 1969) was used to depict the first purchase growth of a new durable product (*see* BASS MODEL). The Bass model suggests that mass media and interpersonal communications are important in determining the speed and shape of the diffusion processes (Mahajan, Muller, and Wind, 2000). The Bass model has three key parameters: the coefficient of innovation or external influence (p), the coefficient of imitation or internal influence (q), and the market potential (m). The diffusion curve is S-shaped when $q > p$, and is more pronouncedly so as the q/p ratio increases (Van den Bulte and Stremersch, 2004). Recent interpretations (Mahajan, Muller, and Peres, 2008) regard the internal coefficient q to represent all consumer interdependencies, including signals, externalities, and interpersonal communications.

Interpersonal communications take place when consumers actively engage in collecting and processing information from previous adopters. Consumers may also be influenced by nonpersonal information, or signals from the market such as information on the number of prior adopters. The utility of the innovation may also increase as more consumers adopt a product, and hence network effects may influence adoption.

The diffusion curve is related to the concept of the PRODUCT LIFE CYCLE (PLC) (Golder and Tellis, 2004). New products often see an initial phase of low sales (introduction), followed by a period of rapid increase in sales (growth), followed by a period of slowdown in sales (maturity), and a period of steady decline in sales (decline). Recent research has documented two distinct transition points – takeoff, marking the transition from the introduction to the growth stage of the PLC (*see* TAKEOFF), and slowdown, marking the transition from the growth to the maturity stage of the PLC (Agarwal and Bayus, 2002; Goldenberg, Libai, and Muller, 2002; Golder and Tellis, 2004).

DRIVERS OF DIFFUSION

Apart from consumer interdependencies, the diffusion of innovations is broadly thought to be influenced by three factors: the characteristics of the innovation, the characteristics of the adopters, and firm strategy.

Characteristics of the innovation. The specific characteristics of innovations may influence their diffusion. Rogers (1995) outlines five characteristics of innovations that may influence the rate of adoption – *relative advantage* or the degree to which an innovation is better than the idea it supersedes; *compatibility* or the extent to which an innovation is perceived to be consistent with a consumer’s past experiences, values, and lifestyle; *complexity* or how difficult it is for a consumer to learn to use the new innovation; *trialability* or the extent to which the product can be tried on a limited basis; and *observability* or whether the benefits of this new product can be easily explained and demonstrated.

Researchers on diffusion of durable goods have observed that information or entertainment products (referred to as *brown goods*, *consumer*

electronics items) diffuse faster than work products (referred to as *white goods*, *home appliances*), possibly because they are more visible, used by many more members of a household, and are often status symbols (Chandrasekaran and Tellis, 2007).

Characteristics of adopters. Diffusion scholars have identified certain adopter categories on the basis of innovativeness, or how early individuals in a social system adopted an innovation. On the basis of the noncumulative distribution of adopters, which takes the form of a bell-shaped curve, Rogers (1995) distinguished five categories of adopters, which include the innovators (2.5% of adopters), early adopters (13.5%), early majority (34%), late majority (34%), and laggards (16%). Mahajan, Muller, and Srivastava (1990) derive this classification from the Bass diffusion model with innovators (0.2–2.8% of adopters), early adopters (9.5–20%), early majority (29.1–32.1%), late majority (29.1–32.1%), and laggards (21.4–23.5%).

The innovators and early adopters (the early market) are often the target of a firm's marketing efforts, since it is believed that they are more innovative, are often the opinion leaders, and hence influence the actions of later adopters. Recent research, however, questions this approach arguing instead that the social contagion process is broken at the point of transition from the early market to the late market because of a lack of similarity between, and communication across, these adopter segments (Goldenberg, Libai, and Muller, 2002). There is a need to research when such discontinuities appear, what marketing strategies (such as price and promotion) can enable a smooth transition across segments, and whether companies should directly target the main market (Mahajan, Muller, and Wind, 2000).

Firm Strategy. Firm technological choices, price declines, advertising, distribution, and firm entry choices may also have a big impact on the takeoff and diffusion of a new product (Agarwal and Bayus, 2002; Golder and Tellis, 1997; Kuester, Gatignon, and Robertson, 2000). There is, however, little consensus on what

strategic factor dominates in driving diffusion, for instance, on the role of price declines versus firm entry in driving takeoff.

MODELS OF DIFFUSION

Over the past 35 years, a vast body of literature has sought to enrich the basic Bass model by including marketing variables, supply restrictions, multiproduct interactions, incorporating time-varying parameters, replacement purchases, multiple purchases, and trial and repeat purchases, and improved estimation techniques (see, for instance, Chandrasekaran and Tellis (2007) and Mahajan, Muller, and Peres (2008) for summaries and references). This body of research indicates that more realistic models combined with improved estimation techniques can lead to the development of better forecasts of peak sales and the sales evolution during the growth stage.

GLOBAL DIFFUSION

Much marketing research relates to the spread of innovations across nations (*see also* GLOBAL PRODUCT DEVELOPMENT). Marketing research has focused on the nature of global diffusion processes, differences across countries in terms of innovativeness in adoption of new products, drivers of global diffusion, and market-entry strategies. There is an emerging consensus (Chandrasekaran and Tellis, 2007; Dekimpe, Parker, and Sarvary, 2000) that product diffusion is influenced by both *within-country* factors such as the wealth of a country, and cultural dimensions (such as social system heterogeneity, cosmopolitanism, individualism/collectivism) and *cross-country* factors (cross-national learning or lead-lag effects).

There is a great need to reach a consensus on operationalizations of the covariates used in international studies, and to expand the product context to beyond the study of durable goods. A key research question in diffusion is whether there has been acceleration in the *speed* of diffusion, and what are the drivers that lead to such an increase in the speed of diffusion. Recent studies find some evidence for a systematic increase in diffusion speed over time (Van den Bulte, 2000). In the context of rapid globalization, the research

challenge remains to document whether diffusion speed is increasing across contexts, what the drivers of the increase in diffusion speed might be, and whether differences in consumer adoption of new products across countries are also declining with time.

Helen M. Perks

DEFINITIONS

Service innovation management has emerged as a distinct area of practice and academic study since the 1980s. However, compared to the management of “product” innovation, research on service innovation management remains limited and fragmented. A comprehensive review of innovation research published between 1989 and 2004 found that only 6% of the articles in the dataset included services and even fewer papers focused on service innovation explicitly. Compared to the two previous decades, service innovation research has grown rapidly since 2000. However, it is still underrepresented, accounting for only 5% of product development research publications between 2000 and 2004 (Page and Schirr, 2008).

There is a high degree of ambiguity regarding the term *service innovation*. It is often used interchangeably with the construct *new-service development*. Service development has its roots in marketing and service quality, whereas service innovation emanates from economics and business strategy research. The latter body of research is traditionally concerned with theories of entrepreneurship and technological development, whereas the former is concerned with exploring service-development practices and their management. The management of service innovation incorporates the strategic nature of developing and offering new services along with the management of the innovation process itself.

Definitional debates, within both the service innovation and development areas, center on the concept of newness. Such debates are conceptual in nature and are largely based on anecdotal evidence. A classic definition of service innovation (Johnson *et al.*, 2000) concentrates on the nature of the service outcomes. From this perspective, innovation in new services can range from simple incremental-style changes to major radical innovations (*see* RADICAL INNOVATION). More comprehensively, service innovation definitions have incorporated procedural or operational aspects of services.

Synthesizing such debates, service innovation can be categorized in two ways:

- *Service offering innovation*: This is an overarching term incorporating incremental improvements and radical changes to service-performance attributes. Part of the infamous Booz *et al.* (1984) marketing-oriented categorization is frequently applied to services, indicating varying types of newness within the service offering, from both the supplier and customer perspective. Such notions of highly new (breakthrough or radical) or not-so-new (derivative or incremental) focus on the new service offering. The concept of development in the service attributes can also be extended to include the augmented service offer. Here innovation centers on expanding the basic service offering. This is usually conceived as innovation through forms of support (such as delivery, distribution, promotion, expertise, and customization). These definitions take an external final offering perspective. There is no categorical description or indication of the internal development resources or competencies linked to the service innovation (Menor, Tatikonda, and Sampson, 2002).
- *Service process innovation*: The cost and repositioning definitions suggested by Booz *et al.* (1984) encompass innovation in the process, rather than the offering itself. Process innovation within services concerns alterations to the business processes within the organization, such as the introduction of new technology or changes in working practices. Such a definition incorporates newness in the service concept, namely, how the service is offered. Hence this definition provides an indication of the degree of change from existing systems and routines, suggesting levels of internal newness.

The lack of definitional consensus creates problems in empirically researching service innovation. New services are often treated in aggregate, and clarity in definition, prior to investigations, is problematic. The scope of service offerings is also broad and diverse. Service innovation primarily occurs in

2 service innovation management

sectors such as banking and finance, leisure and hospitality, travel services, telecommunications services, information services, facilities management, education, professional/consulting services, and health care. Most academic research has been conducted in the financial-services sector, although high-technology services are receiving recent attention. Services may be offered to end consumers, businesses, or both.

DIFFERENCES BETWEEN PRODUCT AND SERVICE INNOVATION

The management of service innovation is frequently compared and contrasted with that of product innovation. Services differ from products in four fundamental ways and this has major consequences for service innovation management (Fitzsimmons and Fitzsimmons, 2001). First, the output of the service innovation process, namely, the service offering, is inherently a process rather than a tangible entity (although efforts are commonly made to make services less abstract and incorporate physical productlike attributes). As a result, traditional activities of the product innovation process, such as concept development and testing, are difficult to carry out. Further, absence of a tangible goal or outcome can impede a common vision for participants in the service innovation process. This can lead to inconsistency and misinterpretations in the development effort. As services lack the physical attributes of products, ad hoc modifications can be easily made by front-line staff in the delivery of the service. Research has shown that this can result in variable customer-service quality and poor company reputation. Hence, mechanisms to structure or model the service delivery operations are advocated. Further, such intangibility means service innovations are difficult to patent and susceptible to copying by competitors.

Secondly, the heterogeneity of services creates difficulties in standardizing the service experience. Variation at the delivery/consumption point limits the extent to which service innovation can be controlled or managed. It also helps explain why aspects of the service innovation management (such as emphasis on employee

training and customer-management skills) differ from product innovation. As with intangibility, the heterogeneous nature of services complicates implementation of traditional innovation activities, such as prototype or final-product testing with customers (*see* PROTOTYPE). Thirdly, the simultaneous act of production and consumption of services (simultaneity), and fourthly, the perishable nature of services, exacerbate problems of matching of supply, prevent the ability to hold stock, and put much emphasis on capacity planning for service providers. However, the close interaction of the customer with service providers in producing the service has also led to increased opportunities for customer involvement in innovation and service design.

THE SERVICE INNOVATION PROCESS

In essence, service innovation is a difficult and messy activity to manage. Substantive debate, in service innovation management research, centers on the nature of the innovation process in services. Innovation investigators are concerned with whether service organizations employ a formal or informal process in service innovation. Many academics suggest that few service providers have a formalized process (with specified stages or activities) in place. Some take the view that service innovation occurs because of intuition, flair, or luck.

Despite this, prominent scholars advocate the adoption of a systematic process and suggest it contributes to new-service success (de Brentani, 1995; Alam and Perry, 2002). Empirical work researching such structured service innovation processes has predominantly focused on identifying activities that concur with models offered for new-product innovation. These often take a sequenced and staged approach, although it is debatable whether activities occur concurrently or in sequential order. Indeed, a body of research emphasizes the iterative, cyclic, and nonsequential nature of new-service innovation (Johnson *et al.*, 2000; Menor, Tatikonda, and Sampson, 2002). Booz *et al.* 1984 suggested a six-stage model of strategy, idea generation, screening and evaluation, business analysis, development, testing, and commercialization that is frequently adopted in service innovation process research. Such formalized systems can provide rules and

procedures to help structure and guide the development process. Other research offers augmentations pertinent to services. Such new extensions enrich our understanding of the conditions and the environment that support or facilitate the service innovation process. The widely used model suggested by Johnson *et al.* (2000), for example, depicts a four-stage service innovation process, with 13 specific tasks, and identifies the components of the organization that are involved in the process.

As in product innovation, service researchers frequently adopt a staged or time-based approach to understanding or exploring the service innovation process. Such work investigates the core activities carried out at each stage. These are often referred to as *early*, *mid*-, and *late-stage activities*. Early stage activities in service innovation are equivalent to the fuzzy front end in product innovation (*see* FRONT END OF INNOVATION). They concern the creation and analysis of ideas and opportunities (*see* OPPORTUNITY IDENTIFICATION). Idea generation in service organizations is perceived as relatively easy. This perception is linked to the dominant nature of innovation in services, namely, incremental improvements and minor modifications to the service offering. Empirical research has shown that few ideas, in service organizations, are radical and most are copied from competitors, who are identified as the most important source (Johne and Storey, 1998). Not surprisingly, idea generation is found to be undertaken on an ad hoc basis (Easingwood, 1986). The high degree of service copying can also explain a low level of market-research use in service innovation. Further, the lack of prototyping and difficulties in reproducing the in-use service experience make market research problematic. However, academic studies suggest that service managers' perceptions of customer needs are frequently incorrect. Similarly, concept testing is difficult to implement. The challenges of precisely describing or demonstrating service benefits, at the concept stage, are acute, although recent advances in simulation techniques and technology go some way to meeting these challenges. Studies have also indicated that evaluation or screening of service ideas and concepts is usually informal. Beyond traditional financial measures, little

is known about the specific screening criteria employed. However, some research has drawn attention to service organizations' assessment of the potential impact of the new service offering on the image of the service organization. Brand image can act as a protective mechanism against competitive emulation. Hence organisations should ensure that service innovation aligns with a strong reputation.

In the development stage or activity set of service innovation, research tends to adopt two perspectives: the customer-facing service concept and the operations or delivery concept. The first domain is classically conceptualized as *front office* where service staff interact with customers. The latter area is viewed as a set of *back-office* operations and hidden from customers (Menor, Tatikonda, and Sampson, 2002). The customer-facing service concept prioritizes customer experiences and satisfactory customer-service quality. The service operations/delivery concept (Edvardsson and Olsson, 1996) is concerned with efficiencies and volume. It is suggested that this is where internal newness occurs and the chosen service concept is implemented. Of course, both these concepts must work together as an integrated whole. Efforts to align operational goals with customer preferences are emerging.

There has been limited empirical examination of how organizations design the development process. A notable exception is the early and much-cited work of Shostack (1984) who proposed a way to blueprint, in diagrammatic form, the tangible and intangible elements of the process. In effect, such models determine the prerequisites of the service development because the development is only realized through customer interaction.

The nature and effectiveness of late-stage activities, often termed *implementation*, have been studied from a number of perspectives. Several authors highlight the necessity of customer and staff training in implementing the service innovation. This is perceived in terms of customer use of the service innovation and managing customer expectations. Again, scholars point to the paucity of market testing by service organizations. It appears that the benefits of rapid postlaunch feedback, through ongoing customer interactions in service encounters, can

go some way toward compensating for the lack of formal testing procedures.

SUCCESS FACTORS FOR SERVICE INNOVATION MANAGEMENT

Relative to the research on success factors for new “products” (see SUCCESS FACTORS FOR NEW-PRODUCT DEVELOPMENT), which is deemed to have reached maturity, research engaged in understanding and articulating the factors that lead to success in service innovation is fragmented. Service innovation research has typically been of a qualitative and descriptive nature. Large-scale empirical studies, with broad samples investigating the antecedents to service innovation performance, have been minimal. A limitation to conducting such types of research lies in the problematic evaluation of service innovation performance or outcomes (see INNOVATION METRICS). Managers themselves struggle to develop financial criteria to measure service innovation performance, although it remains the dominant measure in practice. Service managers tend to be less systematic in the way they evaluate innovation than in tangible product scenarios. Further, determining the units of analysis in service innovation measurement is problematic. Innovation can be measured at a project or overall development/portfolio level (Johne and Storey, 1998). Metrics may also be used for the service innovation process or the actual service outcome (or both). Reflecting the nature of services, it is generally viewed that soft customer-based indicators (such as customer satisfaction) and internal measures, such as efficiency of service delivery and effectiveness of front-line staff, are more effective. These metrics are more extensively employed in service organizations.

Notwithstanding such performance-measurement problems, a small number of studies have examined factors correlated with success and failure in new services. Although such studies struggle to indicate generalized success factors, there are a few exceptions. de Brentani (1995), for example, found that success is generally associated with offering services that respond to market needs, reflect the organization’s reputation and resources, and are aligned with some form of service-development capability, such as implementation of a formal development

process. A limited number of recent large-scale studies support the positive role of a structured formal innovation process. They have found additional evidence for the positive role of technology and the use of interfunctional teams on the effectiveness of service innovation. Research has also proved that differences in the significance of various service innovation success factors depend on contextual factors, such as the level of service innovativeness (van Riel, Lemmink, and Ouwersloot, 2004).

Environment. Apart from such studies reported above, research on factors influencing service innovation success has largely been conducted in a piecemeal fashion, utilizing anecdotal or case-based evidence. Drawing from such studies, we can conclude that considerable attention has been paid to the organizational environment or climate in service innovation. Some studies have pointed to a supportive or positive environment as an important prerequisite to successful management of service innovation. Specifically, the support and commitment of senior management to service innovation, in terms of setting clear goals and providing necessary resources, has been highlighted (Johne and Storey, 1998). Empirical work suggests that senior management can play a critical role in enabling service innovation, such as providing structures that support information sharing or task rotation. Service studies have also pointed to the need for a clear strategic direction or corporate vision for innovation.

Employees. Substantial empirical research lends support to the notion that the service organization’s staff contribute to service innovation success, as they are integral to implementation and development. Employees fulfill a critical role in recognizing opportunities for innovation, through their contacts and knowledge of customers and competitors. They embody the new service at the moment of delivery. They can differentiate the service from competitors and help clients make the switching decision (Atuahene-Gima, 1996). However, employees are often reluctant to engage in innovation activities as it increases their workload. Research has explored management techniques to encourage and support staff-based innovation activities.

Attention is paid to the need for training, appropriate reward systems, and motivation techniques (Edvardsson and Olsson, 1996). The role of product champions who push the project through the innovation process has also been found to be important. Recent work has explored the way employees and teams work together and interact in service innovation. Drawing on knowledge and learning paradigms, this emerging school of thought focuses on competencies or routines in information or knowledge sharing among employees (van Riel, Lemmink, and Ouwersloot, 2004; Leiponen, 2006).

External actors. Despite the close interaction between supplier and customer in service delivery, empirical research into the role of customers in the service innovation process is embryonic. Since the 1980s the new-product development literature has suggested that close supplier/customer collaboration can bring success (*see VOICE OF THE CUSTOMER*). Concepts drawn from this work has only, since the late 1990s, been applied or explored in the service innovation domain. Traditionally, the customer is perceived as an inactive component of service innovation. The service organization has been tasked to encompass a customer orientation in the design of the innovation process or operations (Edvardsson and Olsson, 1996). This presupposes that the organization has a comprehensive understanding of its customers' needs. More recently, services researchers have explored an increasingly active role of the customer in service innovation. Research has shown that customers can be involved at different stages of the development process, with varying degrees of intensity, but with greater emphasis on involvement at the early stages of service innovation (Alam and Perry, 2002). Similar studies have unraveled the specific objectives of user involvement in innovation, such as time reduction and speedier service acceptance in the marketplace. Such work has articulated the particular innovation activities that customers perform. Explicit customer co-creation in idea-generating activities propels customers toward determining and, to some extent, designing the value they desire. It has been shown that this can lead to more innovative

ideas and service outcomes (Matthing, Sanden, and Edvardsson, 2004).

This greater understanding of the role of customers in the innovation process has fueled further investigation into the way service organizations integrate a broader set of external actors or stakeholders into their innovation process. Innovation in services can be perceived as an outcome of an amalgam of interactions and relationships with numerous actors outside the organization, such as customers, suppliers, distributors, and intermediaries. Managing innovation with a set of external relationships is complex and has started to receive scholarly attention (Syson and Perks, 2004). Organizations are increasingly moving beyond firm boundaries to innovate. Theoretical debate and empirical studies advancing the notion of interorganizational or open innovation (*see OPEN INNOVATION*) abound in the new-product domain. Managing interorganizational service innovation is likely to become a fertile area for research.

CONCLUSION

To date, most researchers have exploited findings from product innovation to better understand the management of service innovation. While our knowledge of product innovation practices is becoming mature, and a substantive theory is emerging, there is considerable debate around the applicability of such advances to service innovation. There are core intrinsic differences between services and physical products. Scholars have drawn from service management and marketing research streams to articulate these differences, which are centered on the outcome from service innovation and the characteristics of the services themselves. Service innovation researchers are moving beyond replication of product innovation advances and service-specific innovation constructs are emerging. However, rarely do organizations offer pure services or physical products. Increasingly, the offerings of organizations combine both product and service elements, and innovation occurs within both domains. Adoption of traditional "product" or "service" models, or the integration of both, is unlikely to capture or explain the complexities inherent in managing innovation in such contexts. To address these

dichotomies, scholars are beginning to draw on new paradigms to understand and explain the management of service innovation. Although still lagging behind “product” innovation in this respect, the incorporation of new knowledge areas into the discipline will ensure that service innovation management is studied from different perspectives. Such advances will build the foundation for the maturity of the discipline.

organizing for innovation

Richard Blackburn

INTRODUCTION

There are actually two halves to getting innovation to the market. One is having a good idea, which is obviously the easier part. And the second is actually getting that idea through the organization. We need to know how ideas take life, and in such a way that they can be navigated through all of the complexities and competing pressures for resources and focus and points of view that all organizations have (p. 3). Tim Brown, CEO/President of IDEO in Edmonson and Feldman (2005).

Being able to be empathic, not only to the end user but to the organization you're working with, is critical to this kind of work. The thing that kills most ideas is not that they're not good ideas, it's that they are not good ideas organizationally or culturally (p. 7). Tim Brown, CEO/President of IDEO in Edmonson and Feldman (2006).

IDEO may be as responsible for the phrase "designing for X" as any design consultancy in the world. IDEO's employees have created awareness within many organizations of the fact that products and services can be designed to achieve a variety of outcomes. Thus, in the phrase above "X" could serve as a stand-in for manufacturing, sustainability, safety, aesthetics, quality, cost, and so on. Picking one or more of these terms as the basis for a firm's design philosophy gives those involved with a design project valued guidance as to how they should proceed.

Similarly, the phrase "organizing for X" can also be used by organizations to determine the underlying values guiding how an organization chooses to put itself together. Firms can organize themselves for efficiency, for flexibility, for quality, for speed to market, and so on. For the purpose of this article, replace "X" with the word "Innovation." The article examines the options that organizations have available for putting themselves together in anticipation of providing innovative products or services to their competitive environment in a timely fashion.

KEY DEFINITIONS

Before beginning this discussion, it would be helpful to provide a couple of key definitions as well as delimit the boundaries of this discussion. In particular, Amabile's (1988) definitional distinctions between CREATIVITY and innovation (*see* INNOVATION TYPOLOGIES) are applied. She defined *creativity* as "the production of novel and useful ideas by an individual or small group of individuals working together" (p. 126). Innovation uses the results of the creative process as its raw material. Thus, from Amabile's perspective, "Organizational innovation is the successful implementation of creative ideas within an organization" (p. 126). For the purpose of what follows, creativity is taken as a given. The issue of interest here is how best to organize to insure the successful implementation of already developed creative ideas.

This article views the organizing process in the same vein as do others in the field, by equating organizing for innovation with how organizations align a variety of important organizational characteristics in service of innovation. This alignment process might also be referred to as *designing the organization*—in this case designing the organization for innovation. A far more expansive view of organizing is taken here than is by some. Organizing is more than simply understanding the organizational structures which might be more or less appropriate for innovation. Organizing, for the purposes of this article, includes consideration of a number of important organizational design characteristics that collectively influence the success an organization has in its innovation process.

Organizations function within a given context and can be described along a number of different characteristics. For example, organizations exist and hope to survive and prosper within a competitive environment. That environment can be described along a number of dimensions that affect managerial perceptions of the levels of certainty and uncertainty about what might happen in this environment in the future. Despite some organizations' best efforts, many aspects of the environment permeate the boundary of the organization affecting directly or indirectly input, throughput, and output

subsystems that keep organizations functioning. Organizations also operate within an external cultural milieu. Increased globalization requires that careful attention be paid toward the cultural differences in markets and in operations.

A more important cultural aspect with regard to innovation, however, is the concept of “corporate culture.” A corporate culture reflects the underlying values, assumptions, and mores that determine how employees are likely to feel and behave (Daft, 2007). Clearly, cultures can value either innovation or tradition. Innovative cultures are considered in greater detail later in this article.

Given perceptions of the external environment and culture, and limited to some extent by the assumptions and values of the corporate culture, top management teams have a number of other design-related or organizing-related decisions to make. First, they must choose the appropriate goals for the organization. Survival is typically the unstated formal goal, but beyond that goals might be related to becoming the largest, the fastest, the cheapest, and so on. Having identified a goal or set of goals, those at the top now have to determine the strategy that must be used to achieve those goals. For example, profitability as a goal can be achieved via a low margin–high volume strategy or a high margin–low volume strategy. Implementing the chosen strategy is often a challenging task, but in so doing top managers must make additional decisions about the appropriate structure, technology, systems, and so on, best able to effectively implement the strategy in pursuit of key organizational goals. Finally, organizations cannot exist without the ingredient that brings all of these elements to life—their people. Without the employees, the organization is merely an empty shell.

The key to organizational success, of course, is for top management to make the right choices regarding each of these important organizational decisions. The key to successful innovation is making the right choices with regard to accomplishing that particular strategy. And regardless of the individual choices to be made, one important overall guiding principle is that the nature of the decisions made and actions taken with regard to these various aspects must all *fit*. For

example, choosing the wrong goals (goals that do not fit), given the environmental and cultural factors, will likely lead to a less-than-successful organization. Should changes be made in goals, for instance, strategies, structures, technologies, systems, and people will likely have to change as well to insure achievement of this revised goal.

When one considers how best to organize for innovation, the puzzle becomes quite complex. To place realistic boundaries around this particular entry, this article focuses on only a subset of the characteristics considered above. It is assumed that someone reading this article has already appropriately examined the competitive environment (*see* CORE COMPETENCIES; COMPETITIVE ADVANTAGE) and made the determination that one of the most important goals for the organization is innovation. The strategy chosen to achieve that goal requires decisions about where to seek/find innovations (internal or external to the organization) (*see* LEAD USERS; OPEN INNOVATION), the timing for innovative products and services (first mover or fast follower, for instance) (*see* FIRST-MOVER ADVANTAGE), and the determination of those participating in the innovation process (internal networks or networks between/among other organizations). Those decisions then necessarily influence decisions about the structure, technology, systems, people, and culture that would best serve to support this innovation strategy in pursuit of the innovation goal. It is assumed that technology, systems, and people are given. Certainly, much could be written about the various technologies and systems that support innovation, but that is beyond the scope of this article. Likewise, the impact of individuals on innovation and the innovation process is substantial, but beyond the focus of this article. The literature about individual creativity is voluminous (*see* CREATIVITY). For all three characteristics, the reasonable assumption made is that the organization will find the technologies, systems, and people necessary to fit with the other aspects in this effort aimed at designing/organizing for innovation. The focus, over the remainder of this discussion, is on two issues: “culturing” for innovation and structuring for innovation.

INNOVATION CULTURES

Daft (2007) defines *culture* as “the set of values, norms, guiding beliefs, and new understandings that is shared by members of an organization and is taught to new members. It represents the unwritten, feeling part of the organization” (p. 361). Culture reflects the observable aspects and behaviors of how an organization functions (the artifacts, symbols, and ceremonies known to employees as well as the nature of personal interactions) as well as the unobservable aspects that reflect the deeper values and assumptions that guide organizational behavior but are quite difficult to identify. In fact, asking employees to discuss these deep-seated values and assumptions is difficult, because it would not be unlike asking a fish to describe water. Its ubiquity makes it nearly impossible to adequately and accurately describe it.

Burns and Stalker argued in 1966 that culture was central to organizing for innovation. They noted that firms need to develop “‘codes of conduct,’ which would enable people to ‘comprehend more eventualities and more information . . . and [in which] the limits of feasible action could be set more widely.’” (Burns and Stalker, 1966, p. 11 quoted in Dougherty, 1999, p. 182) So this concept and how it relates to organizing for innovation is first discussed.

Organizations typically have multiple cultures. However, there is likely an overall set of values and assumptions that guide nearly all employee behaviors through the firm. This overall culture has been greatly influenced both by the societal culture within which the organization was founded as well as the individual values and assumptions of founders and/or key leaders who influence(d) selections of corporate goals, strategies, and employees.

While it is possible to change a corporate culture, it is a very difficult task, given the strength of most cultures. Within this overall corporate culture, one can also find a series of subcultures developed as a function of, say, hierarchical level and/or work unit. Some cultural assumptions guiding behaviors of those at the top of the organization may differ from assumptions guiding behaviors of those at the bottom of the firm. Similarly, cultural assumptions within certain functions, research and development,

for example, will likely differ from some of the assumptions found in manufacturing units. For instance, some manufacturing organizations may develop strong or weak quality cultures (“Quality is Job 1”) or a health-care organization may develop strong or weak safety cultures. Of particular interest in this discussion is what might an innovation culture look like, and how might one be developed as part of the overall effort to organize for innovation?

There is sufficient evidence in the literature to support the general contention that the nature of an organization’s culture, its corporate culture, has a substantive impact on a number of dimensions of organizational performance. Starting with Schein (1992) early consideration of the role of culture in organizations up to a more recent consideration of the relative impact of corporate culture versus country culture (see GLOBAL PRODUCT DEVELOPMENT) on RADICAL INNOVATION (Tellis, Prabhu, and Chandy, 2009), the concept of culture has been linked to organizational performance. One need look no further than the differences in cultures that appear to exist between GM and Chrysler and Google, 3M, Apple, Sony, and so on, to appreciate that the nature of the innovation cultures among these organizations has greatly influenced their successes or lack thereof. Even within an industry, innovation culture differences seem to exist. The lay person likely sees some difference in the innovation cultures in Apple versus Microsoft that are reflected in a number of characteristics that distinguish each organization including their marketing, products, and packaging, for instance.

A variety of studies have advanced ideas about what should be the characteristics or dimensions of an innovative culture. The space available in this format limits the number of innovation culture models that can be examined to three. Scott and Bruce (1994) offer a relatively simple model of an innovation culture suggesting that innovation cultures are most often marked by organizational “support for innovation” (openness to change, supportive of new ideas from employees, and tolerant of diversity among employees) as well as “resource support” (the provision of people, time, material, and money in service of innovation).

Table 1 Important characteristics of an innovative culture, by rank.

| <i>Factors</i> | <i>Today</i> | <i>In 10 years</i> |
|---|--------------|--------------------|
| Customer focus | 1 | 1 |
| Teamwork and collaboration with others | 2 | 2 |
| Appropriate resources (time and money) | 3 | 6 |
| Organizational communication | 4 | 3 |
| Ability to select right ideas for research | 5 | 4 |
| Ability to identify creative people | 6 | 5 |
| Freedom to innovate | 7 | 7 |
| Ability to measure results of innovation | 8 | 8 |
| Encouraging both small ideas and big ideas | 9 | 9 |
| Innovation accountability and goals | 10 | 10 |
| Culture of risk tolerance | 11 | 12 |
| Organizational structures | 12 | 11 |
| Diversity | 13 | 13 |
| Balancing incremental improvements and breakthrough discoveries | 14 | 14 |

Reproduced with permission from AMA/HRI Innovation Survey 2006, p. 18.

At the other extreme, in terms of the number of possible dimensions that might comprise an innovation culture are the results published in 2007 of a survey sponsored by the American Management Association and conducted in 2006 among top executives as to the important dimensions of a culture of innovation (Bear *et al.*, 2006). Table 1 reflects the opinions of over 1300 global respondents to questions regarding the antecedents and consequences of innovation in their organizations now, and their predictions of the relative importance of these same cultural characteristics in 10 years (2016). The authors of this study suggest that there are 14 important characteristics of an innovative culture with customer focus, teamwork/collaboration with others, and the availability of appropriate resources (time/money) identified as the three most important.

Finally, Goffin and Mitchell (2005) propose an innovative culture whose dimensionality falls midway between the extremes considered above. They describe what they label as *the cultural web*. This web, based on the work of Johnson and Scholes (1999), is composed of six aspects of culture supporting an organization's "central paradigm" (pp. 266–268). The central paradigm is a "statement summarizing the main points

about how an organization 'thinks' and 'acts.'" Designed to reflect these most basic cultural assumptions are what they describe as the key aspects of culture as captured by the web:

1. *Organizational structure*: the formal organization. The discussion above would argue that rather than being a dimension of an innovation culture, structural choices are instead influenced by the cultural assumptions.
2. *Power structures*: where the power actually resides in an organization. These structures may or may not overlay the formal organizational structure.
3. *Symbols*: advertising, logos, office styles, titles, dress codes, language, and terminology that are unique to an organization.
4. *Stories*: tales that are shared among employees that capture the essence of key events in the firm's history.
5. *Routines and rituals*: the ways in which employees learn to act toward each other and to process work. These often become the taken-for-granted, unquestioned approaches to dealing with various organizational issues.
6. *Control systems*: formal processes, measurement systems, and reward and recognition systems. What these systems assess and

reward reveals what the organization values and on what employee attention should be focused.

For each of these six dimensions, Goffin and Mitchell (2005) offer what they argue are best practices decanted from three major studies of innovation cultures (Jelinek and Schoonhoven, 1990; O'Reilly and Tushman, 1997; Zien and Buckler, 1997). Their suggestions about ways in which the last five of their cultural aspects can support an innovation culture (pp. 274–278) are summarized below. Organizational structure and innovation will be considered separately in the final section of the article.

1. *Power structures*: Substantial power differences tend to reduce innovation and innovative opportunities. A balance of power within a hierarchy and a willingness to cooperate across units contribute to higher levels of innovation. Training and CROSS-FUNCTIONAL TEAM opportunities can encourage this balanced power structure.
2. *Symbols*: All types of communication, internal and external as well as formal and informal, require a focus on innovation: this involves walking the walk and talking the talk; displays of innovations in prominent locations in the organization and on appropriate web pages. The use of unique plaques and certificates to recognize innovators and their innovations should also be publicly available and displayed.
3. *Stories*: “Managers can be transformational leaders (for innovation) if they develop and constantly tell enlightening stories (about innovation) in staff meetings, interviews, and outside speeches” (Goffin and Mitchell, 2005, p. 275).
4. *Routines and rituals*: Programs that encourage the development of new ideas for both product and process improvements may be as structured as internal venture funding of new ideas, encouraging the use of web sites that allow employees to vote on ideas posed by other employees, or allowing new employees to provide formal feedback on what they feel should be done differently. On the other side of the coin, tolerating

mistakes and/or establishing a mind-set that failure may be a better way of learning than success are two ways of encouraging the risk taking associated with successful innovation. One of the key cultural assumptions of IDEO, the world-renowned design consultancy, is described by its cofounder Tom Kelly: “Failure is part of the culture. We call it enlightened trial and error” (in Thomke and Nimgade, 2000, rev. 2007, p. 4).

5. *Control systems*: Because what gets measured and rewarded is what gets done, the design of metrics and their link to rewards for innovation must be carefully considered. If innovation is desired, then evaluation and reward systems have to measure and reinforce innovative behavior (see INNOVATION METRICS).

STRUCTURING FOR INNOVATION

This final section examines what Goffin and Mitchell (2005) consider as part of corporate culture, but which, it is felt, is a derivative of that culture, namely, the organization's structure. As has been the case with innovation and culture, definitions of structure are numerous. For our purposes, we discuss the formal structure of the organization—how the organization puts its various work units together to accomplish its goals.

There are a number of tensions that those at the top of organizations have to manage as they build their firms. For instance, there is the tension between differentiation (taking complex tasks apart so that they can be done more quickly and efficiently) and integration (putting the results of those differentiated tasks back together into a useful good or service). There is the tension between efficiency (producing at the lowest possible cost) and flexibility/adaptability (producing goods and services to meet specific customer needs).

Dougherty (1999) describes four different tensions that organizations confront when they attempt to organize for innovation. The first is the external-internal tension. This tension manifests in two ways. It can refer to the extent to which the market makes certain innovation demands on the organization, only some of

which the internal organization elements are able to provide. This tension can also relate to how organizations manage the extent to which innovation is sought from sources outside the firm or the extent to which firms outsource the development of innovative ideas to other firms (see LEAD USERS; VOICE OF THE CUSTOMER; FRONT END OF INNOVATION). How to draw organizational boundaries and how to manage across those boundaries contributes to a variety of possible structures.

Second, there may be a tension between the old and the new. “(T)he complexity of work . . . reinforces a tendency to separate and compartmentalize work, locates power in the established business, not new ones, and hinders integrated problem-solving” (Dougherty, 1999, p. 178). This reflects the tension between exploitation (continuing to reap marginal revenues from minor improvements in the current line-up of goods and services) and exploration (the capability to develop new and different goods and services) (March, 1991).

A third tension may arise between what Dougherty calls *strategic determination* and *strategic emergence*. This refers to the innovation required by top-down strategic decisions versus innovations that are allowed to bubble up from the bottom of the firm. The tension here is a lack of really new ideas if top-down innovation only supports changes at the margin versus the possible inability of most bottom-up innovations to build on previous work and/or to fit with the organization’s strategy.

The final tension is the one experienced by those who struggle between the freedom to be innovative and the responsibility to work toward common organizational goals. Larger firms tend to emphasize responsibility over freedom—doing things right; not necessarily doing the right things. Dougherty asks, “How can large, complex organizations solve the problems of normal functioning . . . and still embody the tensions which power innovation” (Dougherty, 1999, p. 181).

As organizations attempt to manage these tensions and organize themselves for innovation, they have a number of structural options available. If efficiency and exploitation are important,

then the costs savings associated with a functional structure suggest that functional innovation teams may be beneficial. These include teams of employees located within the same functional unit. This approach frequently limits the innovative ideas to those affecting a single function, with the teams often providing incremental innovations at best to the firm.

Typically, however, many (most) innovations (most new-product or service innovations) are too complex to be isolated within a single function. In this case, the use of CROSS-FUNCTIONAL TEAM may be the appropriate structural solution. These teams may be colocated or, given the precipitous decline in the costs of communication and computer technology, operate virtually where key functional team members operate at a distance from each other (see VIRTUAL TEAMS). These cross-functional teams usually operate within an existing organizational structure with team members still responsible to their functional managers, but with only “dotted line” responsibility to the leadership of the cross-functional team. One difficulty that often besets cross-functional teams is that the team manager (if one exists) does not have direct authority over team members, meaning that his/her power, influence, and access to necessary resources may be limited.

One structural solution to this problem is in the formation of the heavyweight cross-functional team. Under this structure, the team leader has direct authority over team members, while functional managers now have “dotted line” responsibility for their respective team members. The team leader’s position in this structure is at the same hierarchical level as that of the functional managers supplying team members, and he/she can exercise the necessary power and influence over team members as well as be better positioned to acquire the necessary resources.

Yet another structural option that provides even greater autonomy to those charged with developing innovative products or services is the autonomous team. These teams have strong leaders, and they are structured so as to be independent of the broader organizational hierarchy and culture. Lockheed’s attempt to design a new jet fighter in the early 1940s is probably the first formal use of what they dubbed

Table 2 The scope of the ambidextrous organization.

| <i>Alignment of</i> | <i>Exploitative Business</i> | <i>Exploratory Business</i> |
|---------------------|--|---|
| Strategic intent | Cost, profit | Innovation, growth |
| Critical tasks | Operations, efficiency, incremental innovation | Adaptability, new products, breakthrough innovation |
| Competencies | Operational | Entrepreneurial |
| Structure | Formal, mechanistic | Adaptive, loose |
| Controls, rewards | Margins, productivity | Milestones, growth |
| Culture | Efficiency, low risk, quality, customers | Risk-taking, speed, flexibility, experimentation |
| Leadership role | Authoritative, top down | Visionary, involved |

the “*skunkworks*.” It is also the case that any of these team-based structures can operate with colocated team members but can also be structured virtually with team members located at a distance from each other.

These structural options above seem for the most part to be “grafted” on to the existing organization structure. While this is not necessarily a problem, particularly if other key organizational characteristics (importantly, corporate culture) are supportive of the innovation goals and strategies, more recently, some have suggested that organizations consider more substantive structural changes that produce what is described as the *ambidextrous organization* (Daft, 2007; O'Reilly and Tushman, 2004).

One of the tensions or trade-offs that organizations confront in an environment calling for more effective innovation is between the flexibility of the organic design and the structure of the mechanistic design. As Daft notes, “The challenge for managers is to create both organic and mechanistic conditions within the organization to achieve both innovation and efficiency” (Daft, 2007, p. 407). The issue is that while organic organizations are better at getting employees to generate innovative ideas, they are not the best means for actually implementing ideas. On the other hand, mechanistic designs may be required to actually implement innovative ideas once they have reached that stage of the development process. As O'Reilly and Tushman (2008) note, “... the routines, processes, and

skills required for exploitation are fundamentally different than those required for exploration . . .” (p. 188).

Enter the ambidextrous organization. This type of organization is designed to behave organically when exploring for new ideas and mechanistically when determining how to exploit these innovations. This design or structure can be applied within a unit or between units within the larger organization. In their research, O'Reilly and Tushman (2004) found that organizations that have been successful in both exploiting the success of their present product/service line(s) and exploring future innovations structurally separate the exploratory units from the exploitative ones. But “at the same time, they maintain tight links across units at the senior level” (O'Reilly and Tushman, 2004, p. 2). Table 2 provides information as to the design differences that arise in the units that might comprise an ambidextrous organization.

Each of these structural options comes with its own set of advantages and disadvantages, and the choice of the appropriate structure depends on how well a particular structural approach fits with the other elements of the organization's design. For instance, Daft (2007) suggests that the culture of an organization should reinforce the strategy and structure of an organization (and vice versa). The importance of the appropriate fit among the various organizational characteristics identified above should not be underestimated.

CONCLUSION

In summary, Kanter (1988) asserts that by its nature the innovation process is uncertain, knowledge intensive, controversial, and cross-functional. If these characteristics of innovation are still accurate, then her remarks made more than 20 years ago are still true today as we think about the best ways to organize for innovation.

It (innovation) is most likely to flourish where conditions allow flexibility, quick action and intensive care, coalition formation, and connectedness. It is most likely to grow in organization that integrated structures and cultures emphasizing diversity, multiple structural linkages both inside and outside the organization, intersecting territories, collective pride and faith in people's talents, collaboration and teamwork (p. 172).

Similarly, the conclusions drawn by the authors of the AMA/HRI Innovation Survey are also compelling:

The future challenge for companies will be to develop an 'agile mindset' that allows them to quickly respond to changes in the marketplace, new technologies, geopolitics and other factors. The standard organizational pyramid with the vertical hierarchy of boxes, while not disappearing entirely, is likely to lead to a more over-lapping and highly linked set of satellites connected by information technology. A growing number of organizations will be characterized by an integrated and dispersed set of mobile, multi-functional expert teams rather than by separate functions and distinct regional offices. The key will be to quickly focus and organize resources to support strategic initiatives, including innovation goals. (Bear *et al.*, 2006, p. 45).

lead users

Nikolaus Franke

WHO ARE LEAD USERS?

Lead users represent valuable external sources for companies seeking ideas and concepts for RADICAL INNOVATION, be they products or services. The need to systematically transcend the company's internal resources when innovating, particularly at what is called the FRONT END OF INNOVATION of the innovation process, is highlighted in the literature on OPEN INNOVATION.

Lead users are defined as members of a user population who display two key characteristics: first, they anticipate relatively high benefits from obtaining a solution to their needs—and may innovate as a result. Second, they are at the leading edge of important trends in a given marketplace—and so are currently experiencing needs that will later be experienced by many users in that marketplace (von Hippel, 1986).

In a number of studies from the late 1970s and 1980s onward, Eric von Hippel of Massachusetts Institute of Technology (MIT) and several of his colleagues have observed that in very different industries—ranging from high-tech areas such as scientific instruments or thermoplastics to consumer markets such as outdoor equipment or skateboards—a huge percentage of the most important innovations were originally developed by the product users, not by the producing firms (see von Hippel, 1988; von Hippel, 2005 for overviews). In this context, the term *user* refers to the functional role of the institution and means that with respect to the product in question, the institution expects to derive benefits from its own product *use*, not from *selling* the product. Therefore, “users” may be individual end users (e.g., consumers in the food market) or firms (e.g., a high-tech manufacturer who uses a specific machine in its internal production process).

The finding that users can be very active in innovation seemed to contradict canonical market research experience from “VOICE OF THE CUSTOMER” techniques, which holds that customers are at best capable of articulating unsatisfied present needs but are hardly able to provide information about future needs or

even to provide ideas, concepts, and solutions to match those needs. This puzzle was resolved by the introduction of the “lead-user” concept. Although it may be true that many customers are unable to provide active input in new-product development tasks, there is a specific subgroup of users—known as *lead users*—who are indeed creative and innovative. Lead users are able to provide direct input in new-product development tasks and have often developed prototypes (see PROTOTYPE) of new-product solutions for themselves (personally or for the company they work in) or for their communities (von Hippel, 1986; Franke and Shah, 2003; Lüthje, 2004; Lettl, Hiennerth, and Gemünden, 2008). On this basis, Urban and von Hippel (1988) proposed the “lead-user method,” which allows companies to benefit from the creative potential of lead users.

THEORETICAL FOUNDATIONS OF THE LEAD-USER CONSTRUCT

The original theoretical thinking that led to the definition of “lead users” as having (i) high expected benefits from an innovation and (ii) a position ahead of an important market trend was built on findings from two different streams of literature (von Hippel, 1986; 2005).

The “high expected benefits” component of the lead-user definition was derived from research on the economics of innovation. Studies of industrial product and process innovations have shown that the greater the benefit an entity expects to obtain from a required innovation, the greater that entity's investment in obtaining a solution will be. The benefits a user expects can be higher than those expected by a manufacturer, for example, if the market is new and uncertain, if customer preferences are heterogeneous and change quickly in the market, or if the costs of innovation are lower for users than for manufacturers owing to the “stickiness” of preference information. Naturally, the benefits a user expects will vary depending on situational variables. Component 1 of the lead-user definition was therefore intended to serve as an indicator of innovation likelihood.

The second component of the lead-user definition, namely, being “ahead of an important marketplace trend,” was included because

2 lead users

of its expected impact on the commercial attractiveness of innovations developed by users residing at that location in a marketplace (von Hippel, 1986). Studies on the diffusion of innovations regularly show that some adopt innovations before others. Furthermore, classic research on problem solving reveals that subjects are heavily constrained by their real-world experience through an effect known as *functional fixedness*. For example, those who use an object, or see it used in a familiar way, find it difficult to conceive of novel uses. Taken in combination, these findings led to the hypothesis that users at the leading edge would be best positioned to understand what many others will need later. After all, their present-day reality represents aspects of the future from the viewpoint of those with mainstream market needs. Component 2 of the lead-user definition therefore indicates

the commercial attractiveness of an innovation created by such a user.

Note that these two components of the lead-user definition are conceptually independent. They stem from different areas of literature, and they serve different functions in lead-user theory. Although they may be correlated in some cases and to some degree, especially as a position ahead of the trend may well be accompanied by a high need for innovative solutions, this is not necessarily always the case. Therefore, the lead-user construct can be described as consisting of two (formative) dimensions.

These theoretical considerations were tested and confirmed in a study of 456 kite surfers and their user innovations (Franke, von Hippel, and Schreier, 2006). Figure 1 shows the main findings in graphic form: first of all, we see

Figure 1 Innovation likelihood and innovation attractiveness as a function of the two lead-user dimensions (adapted from Franke, von Hippel, and Schreier, 2006).

that both components are indeed relatively independent. Users (represented by small dots or bubbles) are broadly distributed, and a considerable number of users are far ahead of the trend but would hardly expect any benefit from innovating. At the same time, many users would derive high benefits from an innovation but are not at all ahead of the trend. Second, moving from left to right (i.e., from low to high benefit), we can see that the proportion of innovators (represented by the gray bubbles) rises relative to the number of noninnovating users (represented by the small dots). Third, moving upwards (i.e., from a position behind the trend to a position ahead of the trend), we can see that the attractiveness of innovations (represented by the size of the gray bubbles) increases. Hence, both the proportion of users with innovative ideas and the commercial attractiveness of the innovations they develop are highest in the lead-user quadrant (top right) of Figure 1.

The graph also illustrates what Morrison, Roberts, and Midgley (2004) discovered, namely, that the lead-user construct is distributed over a continuum: users are not simply “lead users” or “non-lead users” (as some earlier literature appears to suggest); instead, they may have *more or fewer* lead-user characteristics.

Recent studies have found that an individual’s “lead userness” with respect to a specific market is correlated with other characteristics, such as innovativeness, adoption behavior, or opinion leadership (Schreier and Prügl, 2008). This suggests that lead users may very well constitute valuable resources in other phases of the innovation process, such as NEW-PRODUCT FORECASTING, PRODUCT TESTING and CONCEPT TESTING, PRODUCT DESIGN, and the DIFFUSION OF INNOVATION.

If lead-user innovators are individuals, the question arises as to how they tackle the often

complex task of product development. An individual may well develop an idea, but developing the idea into a functioning prototype often requires diverse and specific knowledge, which a lone individual is unlikely to possess. As a result, lead users often organize into communities in order to complement their capabilities, both in off-line communities (Franke and Shah, 2003) and in online communities such as open-source networks (*see* OPEN SOURCE), or other forms of virtual institutions. This makes lead users easier to identify for firms seeking to benefit from their creative potential.

THE LEAD-USER METHOD

The lead-user method proposed by Urban and von Hippel (1988) is a managerial heuristic that enables companies to search for commercially attractive user innovations and identify new business opportunities systematically (*see* OPPORTUNITY IDENTIFICATION). Usually, this method is described as consisting of four phases (Figure 2): (i) the start phase, (ii) the identification of major needs and trends, (iii) the identification of users leading those trends, and (iv) the lead-user workshop, in which concepts are designed (von Hippel, Thomke, and Sonnack, 1999; Lüthje and Herstatt, 2004).

The start phase involves defining objectives (e.g., “finding an innovative solution to problem X” or “identifying an innovative product concept in market Y”) and setting up a CROSS-FUNCTIONAL TEAM.

In the second phase, the three to five most important trends are selected. This selection is usually based on interviews with experts, information from online forums, and literature research. Their function in the process is to narrow the problem and to allow a systematic search for lead users. The trends are those

Figure 2 The lead-user method.

4 lead users

Figure 3 Search strategies: screening and pyramiding (adapted from von Hippel, Franke, and Prügl, 2009).

dimensions in which lead users are far ahead of the mass market.

The third phase involves searching for lead users. Earlier studies usually employed a mass screening approach in which a large sample of users (typically from customer databases) was systematically filtered to identify those users who score highest in both lead-user dimensions. More recently, lead-user studies have increasingly turned to the pyramiding method for the purpose of lead-user identification (von Hippel, Thomke, and Sonnack, 1999). In the latter approach, researchers start with a few users and ask them who has especially high needs and is leading the trend. Those users are then contacted and asked the same questions, and the process continues until a sufficient level of “lead useriness” is achieved (which is usually the case after two or three steps). Recently, experiments have demonstrated the superior efficiency of the pyramiding search strategy compared to screening as shown in Figure 3 (von Hippel, Franke, and Prügl, 2009).

Another advantage of the pyramiding approach is the possibility of identifying individuals outside a predefined population or sample. Particularly analogous markets, that is, markets that are different from the target market but characterized by the same trends, are valuable sources in the search for lead users. Consider the example of a lead-user study that aims to find methods of preventing infections in clinical surgery. For this purpose, one important trend would be “methods for increased air purity.” Outside of leading hospitals, experts from the analogous field of chip production or CD production may also be able to provide valuable creative input. Two arguments can be brought forward as to why it might make sense to ask such people: first, they might possess solution-related knowledge that is worth transferring from the analogous field to the target field, and second, they are less likely to be blocked by existing solutions in the target field.

In the fourth and final phase, the lead users identified are invited to a two- or three-day

workshop in which company members from different areas (e.g., RESEARCH & DEVELOPMENT, production, and marketing) also participate. At these workshops, classic techniques such as BRAINSTORMING, group discussions, and others are used to capitalize on the CREATIVITY of the participants. It is important for the company to address the issue of INTELLECTUAL PROPERTY RIGHTS intellectual property rights prior to the workshop and to ensure that the ideas and concepts generated can be commercialized without the risk of legal infringements. In many cases, this is less problematic than one would suppose. Harhoff, Henkel, and von Hippel (2003) have shown that, in many cases, it is economically profitable for a user to reveal his/her innovations freely (e.g., because he or she will profit from the use of the resulting product).

Two studies have compared the commercial success of the lead-user method with the output of more traditional methods of idea generation (such as focus groups in quantitative terms and found that the ideas generated by a process using input from lead users exhibit a far higher level of commercial attractiveness (Urban and von Hippel, 1988; Lilien *et al.*, 2002). In the latter study, the authors compared 47 real funded projects at 3M. They found that the projected commercial success of projects based on the lead-user method (\$146 million) was, on an average, 8 times higher than that of projects based on traditional methods (\$18 million). The projects also differed significantly in terms of novelty, originality, strategic importance, and radicalness. This underscores the potentially high value of lead users in marketing and new-product development.

intellectual property rights

Ludmila Striukova

DEFINITION

Intellectual property (IP) refers to *intangible assets* related to knowledge and ideas. Protection of IP differs from protection of tangible assets, as intellectual assets are generally costly to create, but easy to copy. IP is protected by registered rights, such as design rights, trademark and patents, and unregistered rights, such as copyright and trade secrets.

The main rationale behind intellectual property rights (IPRs) is to protect the inventor and to ensure that the inventor can appropriate sufficient returns from innovation, and to encourage further innovation. Indeed, strong IP protection can be beneficial to both small (Grindley and Teece, 1997; Gans and Stern, 2003; Rivette and Kline, 2000) and large (Kalamas *et al.*, 2002) companies. On the other hand, there is evidence that a too rigid IP regime can hinder innovation (Merges and Nelson, 1990; Scotchmer, 1991).

COPYRIGHT

Copyright protects original literary, dramatic, musical, and artistic work. However, it protects the expression of ideas, rather than the ideas themselves. The original copyright law in England and Scotland (1709) gave copyright for 14 years plus additional 14 years if the author was still alive. The duration of copyright, however, has since been increased. Nowadays, in most countries, copyright lasts for the life of the author plus 70 years. Furthermore, recordings are protected for 50 years in Europe and 95 years in the United States. Main contemporary issues related to copyright are the digitalization of data and software-related issues. and software-related issues are the main contemporary issues involving copyright.

While the protection provided by copyright has been considered for centuries as rather adequate, its effectiveness has been recently challenged by the advent of digital technology. Traditionally, copyright was infringed only by a limited number of individuals or companies, which is one of the reasons for its success.

However, the fact that digital goods can be reproduced at nearly no cost without losing quality has enabled almost anybody to become an infringer. Because of that, the protection of copyright has become an issue for music and film industries (among others) who claim that they lose millions of dollars per year because of the illegal distribution of digital goods and are in a constant struggle to stop individuals from sharing copyrighted content among themselves. Napster, for instance, one of the first popular file-sharing services, was shut down in 2001 when it was found liable of infringement, not because Napster itself infringed any copyright, but because it enabled copyright infringement.

Similarly, in 2005, the Authors Guild, the Association of American Publishers and individual authors and publishers sued Google, which scanned books and allowed its users to search through them. The lawsuit was settled in October 2008 when Google agreed to pay compensation to the copyright holders whose books had already been scanned, to cover the cost of creation and maintenance of a register with information about books and their usage. Also, copyright holders were given control over how much of the content is included and they now receive a percentage of the revenues generated by this activity.

Though the outcome of the suit provides copyright holders with a remuneration, it also undermines one of the most important goals of Google Books, which was to provide access to rare or out-of-print books or to provide access to those who live far from bookstores or public libraries. This may happen if the copyright holders choose not to include their books or if the books are “orphan works,” that is, when copyright owners cannot be identified. Furthermore, the settlement does not allow short snippets of text to be included in Google search, despite this falling under “fair-use” category of copyright law.

Because of the steep increase in the number of copyright infringers and the quasi impossibility of initiating litigation against all of them, copyright holders have changed strategy and have attempted in advance to prevent infringement from taking place. Digital right management (DRM) is a set of technologies that aims to

prevent consumers from illegal copying and sharing. The general idea of DRM is to distribute encrypted media files that need to be decrypted before use. Such decryption requires connecting to a central server that holds a database of legitimate users and of rights each user has in regard to the usage of a particular digital product. While DRM was originally designed as fit to curb piracy, there are numerous ways to circumvent existing DRM systems (Rayna and Striukova, 2008a).

In addition, largescale adoption of DRM technologies needed for it to impact on piracy has been hindered by concerns such as the breach of privacy caused by personal data necessarily collected by the central servers as well as the lack of flexibility introduced by these technologies. Technologies such as DRM make it possible to collect personal data on regular basis even without customers' knowledge and to be used for price discrimination. Rayna and Striukova (2008b) propose two solutions to the increasing problem of loss of piracy: keep the current DRM technology, but to reward customers for disclosing their personal information, or to establish anonymous and more flexible DRM systems.

Another current issue associated with copy-right is related to the protection of software. The source code of software is protected by copy-right, however, there have been cases when the structure of the program and its "look and feel" have been copied and while, the source code was not copied and differed between the two pieces of software, this has nonetheless be ruled out as a copyright infringement.

TRADE SECRET

A trade secret is a piece of information that provides an organization with a competitive advantage over other companies; for example, formulae, plans, and manufacturing processes. It is indefinite, however, as with any secret, this advantage is lost if someone (presumably a competitor) uncovers it. A company's projected sales figures may also constitute a trade secret because that information is valuable to a competitor.

A good example is the formula for Coca-Cola, which has been kept a trade secret for more than 120 years. The strong protection against

competitors provided by the trade secret led to Coca-Cola not being sold in India until 1991, because Indian laws required, before this date, that the formula had to be revealed prior to commercialization. Revealing trade secrets can be made illegal by making employees sign nondisclosure agreements. In 2007, three employees of Coca-Cola received prison sentences for trying to sell, before its release, samples of a new flavor of Coca-Cola to PepsiCo for \$1.5 million.

DESIGN PROTECTION

Design rights protect the appearance of the whole or part of a product, in particular contours, shape, and texture. Design protection can be registered and, subsequently, unregistered. In Europe, registration of industrial design can last up to 25 years, subject to renewal every 5 years. In Japan, registration of a design grants a protection for 15 years. In the United States, design is protected by utility patents. In addition, in the United Kingdom, unregistered design is protected automatically for 15 years. It can be noted that two-dimensional design (e.g., a drawing or a logo) also can be a subject to copyright protection. However, copyright protects only the two-dimensional object (e.g., a sketch of a dress) and cannot be applied when the project becomes three-dimensional (a dress itself). Design protection is important for many industries; however, some industries, like the fashion industry, do not impose strict enforcement. First of all, the life of a fashion design is so short that it does not make sense for companies to apply for design protection and to subsequently enforce it; furthermore, copying in fashion industry speeds diffusion and makes the obsolescence of fashion designs more rapid, resulting in new models and designs (Raustiala and Sprigman, 2006).

TRADEMARK

Originally, the purpose of a trademark was to certify the origin of goods. However, nowadays, its role has changed, since trademarks are often licensed out and one company can hold multiple trademarks. In practice, a trademark is used by companies to attract consumers when the brand

name protected by the trademark has earned a positive reputation. To be of value, however, a trademark should be known and appreciated by a large number of people; maintaining this may therefore be quite costly (Smith, 1997).

A trademark is initially granted for 10 years and can then be renewed indefinitely as long as it is in use. If a trademark becomes generic (i.e., the name has become a generic designation of a particular kind of product in the popular language, such as hoover, elevator) it may be revoked. This may also happen if a trademark is no longer in use.

The breadth of trademark has been enlarged by the advent of the Internet. Indeed, domain names are now considered as an extension of the trademark and, therefore, priority is given to the trademark holder when an application is made for a domain name.

PATENT

A patent grants an inventor limited monopoly in exchange for a disclosure of information about their invention. There are four broad theories about the principal purposes of patents (Mazzoleni and Nelson, 1998): patents motivate useful invention and without a strong patent system there will be no invention, facilitate wide knowledge about the use of inventions by inducing inventors to disclose their inventions when otherwise they would rely on trade secrets, induce the investment needed to develop and commercialize inventions and enable the exploration of broad prospects. Granting broad patents on early stage inventions enables inventors to carry out subsequent research and development within the area of the patent claim and be protected by the same patent.

Patents last for 20 years from the date of filing. To be granted a patent, an invention has to be new, nonobvious (novel), and capable of industrial application. The nonobvious clause was only introduced in the United Kingdom in 1902 and in the United States in 1966 (Graham vs. John Deere).

In the United States, the rights are given to those who were first to create an invention and not to those who were first to file for a patent. Also, in the United States, the inventors have one year after they commercialize their invention

to file for a patent. Patents are a territorial right and have to be filed for, in different countries. In the European Union, the patent system has moved toward a greater harmonization and the European Patent Office (EPO) was opened in 1978 to centralize and ease patent applications. However, European patents still do not exist and applicants still need to apply (and pay) for different countries. Yet, the creation of the EPO has facilitated the application process by establishing a one-stop central application service in Europe. It is to be noted that the EPO is only in charge of granting patents, which then have to be enforced separately in the different countries. Also, sometimes, a patent protecting one invention can be valid in one country, but judged to be invalid in another country. Until recently, patents had to be translated in all European languages, however, since May 2008, most of the European countries relinquished the requirement that patent has to be translated into their national language, saving patent applicants up to 40% in fees.

The domain of application of patents has evolved over time. In the United States, it became possible to patent software in the 1980s, and business methods in 1998. In the European Union, "pure" business methods are not patentable, however, if a method is technical it can be related to doing business and still be patentable.

PATENT MANAGEMENT

The changing role of patents made companies take a more strategic approach to patent management (*see also* LAUNCH STRATEGIES; GROWTH STRATEGIES; MANAGING MATURE PRODUCTS). While patents have existed now for a long time, the value that resides in them has long been overlooked by firms and it is only recently that companies started to create special departments to acquire and manage IP, aiming at maximizing value through IPRs. According to Reitzig (2003), factors affecting the value of a patent include its lifetime, its breadth, and family size, disclosure, the difficulty of inventing around, legal argument, and backward and forward citations. The value of a patent portfolio may be higher than the sum of the value of individual patents, since patent portfolios might,

4 intellectual property rights

for instance, allow companies set standards. The value can only be created if companies have enough resources to monitor patent infringements and subsequently sue the infringers (when patents are infringed it is possible to sue the infringer to recover the profits related to in-house commercialization of products or licensing out, which were lost owing to the infringement).

To use patents effectively (i.e., to create both financial and nonfinancial value), patents can be used in various governance structures: licensing-in, licensing-out, cross-licensing, and patent pools.

Licensing is typically seen as an agreement between the licensor and licensee, where the former permits the latter to use the property rights in commercial applications. This agreement is usually officially signed and it implies that the licensor remains the proprietor of the rights, whereas the licensee pays fees (royalties) to use the patent.

In terms of exclusivity, licenses can be granted either on an exclusive basis (to a single licensee) or on a nonexclusive basis (to many licensees). Exclusive licenses can be restricted by time, geographical territory or market, or by technological field of usage. An exclusive license provides the licensee with a potentially large market power. This type of license is sometimes demanded by companies who plan to invest a substantial amount of money in product development and/or manufacturing. However, there is usually less risk involved for licensor under nonexclusive agreements because having more than one licensee increases the chances of a final product being successful.

In addition to the exclusivity, licensing agreements have other types of clauses (OECD, 2004). Examples of such clauses are as follows: “requirements to work inventions” clauses to make sure that the licensee really tries to commercialize a technology within a reasonable period of time; “requirements to work invention” to permit the patent owner to stop the contract in cases where technology commercialization never takes place; and “reach-through” clauses to secure a licensor’s future revenues from licensed technologies, by including contract royalties on future products developed by using a licensed technology; and “property rights on improvements” as both the

licensor and licensee are to obtain the rights on these improvements.

Both licensing-in and licensing-out agreements help companies to share risk or liability and also to avoid or to settle litigations and accelerate the development of their technologies. In addition, licensing-in agreements provide firms with the opportunity to develop technology beyond their expertise. Furthermore, in terms of R&D, licensing in helps save on research costs, while licensing out enables to recover all or part of the money spent on R&D. In addition, licensing-out agreements help generate profit. In the case of licensing-out agreements, companies can also achieve a wider diffusion of their technology, which adds value to existing products and also permits companies to test new applications for both new and proven technologies. Other advantages of these agreements is that they enhance customer loyalty, they match promising technologies with the resources needed to bring them to the market, they help to get around trade barriers, they help set standards and, finally, they build relations leading to further collaboration. In addition, licensing-out agreements give an opportunity for companies to increase the scope of usage of their patents. They also give the licensor a chance to profit from the technology entering a new or a foreign market without investing additional resources.

One of the disadvantages of licensing-in is the dependence on the quality of the patents involved in the agreement. For example, the value of the licensed-in patent can be reduced if this patent is less useful than expected or if a third party is infringing the licensor’s patent. Licensing-in often implies sharing the patent with other company/ies and, therefore, can force companies to invest more in product development or in marketing. The licensed technology might also become obsolete rapidly and, therefore, the revenue stream will stop, which, in turn, will make the licensed patent a liability rather than an asset. Moreover, the license might be stopped or not be extended by the licensor, which, of course, results in companies losing their customers, revenue, and even, sometimes, reputation. In the case of licensing-out the licensor very often depends on how well and how quickly the licensee develops the licensed patent into a commercial product and the subsequent

success of this commercial product. Another risk is that the revenue generated from licensing patents out can be sometimes lower than the costs of monitoring the licensee's activities. Very often the patent has to be adapted for the licensee, which might result in higher costs for the licensor and, as a consequence, in lower revenue. Licensing-out agreements also might diminish the licensor's control over standards and specifications and, furthermore, its reputation might be damaged or even destroyed by the actions of the licensee.

Cross-licensing agreements usually exist between two parties, and in some rare cases more parties are involved. Cross-licensing agreements imply that companies exchange selected patents on a royalty-free basis, as, in theory, the patents brought by each company in the agreement have the same value. Generally, companies cross-license all the patents within a field of use for a fixed period (this includes existing patents and those that are still pending). The period of cross-license and residual rights reflect the technology life cycle.

There are two main motivations for cross-licensing: they provide companies with freedom to invent without the risk of patent suits and cut down the transaction costs of identifying and monitoring infringements. This type of agreement can be quite extensive and is based on a contract between the parties not to sue each other for infringing of patents they put in the agreement. The agreement may also include pending patents or any other related patents granted in the future. Basically, a cross-licensing agreement can help solve the problems attributed to a patent thicket, which is, according to Shapiro (2001), an overlapping set of patents requiring multiple licensees for those who plan to commercialize a certain technology. Cross-licensing agreements, in this case, reduce the uncertainty associated with the investments in R&D.

The last form of patent governance is patent pools. Patent pools are defined as follows: "A patent pool involves a single entity [. . .] that licenses the patents of two or more companies to third parties as a package" (Shapiro, 2001). Patent pools are characterized by multi-party ownership. They may include either only current patents or also any future changes in

these patents. A typical pool makes all the pooled patents available to each member of the pool. Pools also usually offer standard licensing terms to licensees who are not members of the pool. In addition, a typical patent pool allocates a portion of the licensing fees to each member according to a preset formula or procedure.

The basic economic rationale of patent pools is that they significantly reduce the transaction costs of exchanging rights, when compared to a series of bilateral licensing deals. When patent pools are not used as a cover for a cartel, they increase significantly the efficiency of the patent system, as many industries have discovered over time. Department of Justice and Federal Trade Commission (1995) in the United States assert that patent pools need not be open to all who would like to join unless (i) excluded firms cannot effectively compete in the relevant market for the goods incorporating the licensed technologies and (ii) the pool participants collectively possess market power in the relevant market.

The advantages and disadvantages of patent pools overlap with those of cross-licensing agreements. Participation in both types of agreements results in considerable financial savings, through both reduction of royalty stacking and reduction of transaction costs. Some other advantages are related to the creation of relationships between partners. Both governance structures, especially patent pools, are very useful in setting standards. Other advantages are attributed to the sharing and coordinated launch of technology and also clearance of other companies' blocking position. The disadvantage of both cross-licensing agreements and patent pools is believed to be such that agreements might discourage investment in R&D and that members might defect and breach the contract.

Cross-licensing agreements are often more favorable than patent pools because the agreements usually do not involve royalties. In the former, when royalties are involved, they are very often easy to negotiate, which is rarely the case with patent pools as they are multiparty agreements and require a lot of negotiations. As for patent pools, their ultimate advantage lies in the fact that they include a lot of partners at the same time and, in this sense, offer access to a greater amount of skills and resources.

A specific problem related to patent pools is that the great number of patent owners may make it difficult to administrate the pool, to coordinate its development, to negotiate, and to allocate royalties. Patent pool administration costs should not offset transaction savings. A further difficulty is that not all the patents included in patent pools are essential. The fact that only essential patents should be included in the portfolio is the most important feature of a patent pool because it helps ensure that the portfolio patents are not competing with each other. Essentially, all of the patents included in a pool must be the ones that can be used to block the implementation of the standard embodied in the patent pool. It should then lower the costs of the manufacturers who need access to these patents, because prospective licensees will be able to negotiate just once, rather than many times, for all required patents. On the other hand, patent pools may increase the costs of licensees if they include patents that would not otherwise be needed by the licensees.

The Bayh-Dole Act in the United States in 1980s, which made it possible for the United States universities to commercialize their patents, resulted in universities joining the patent race. Similarly, universities in other countries followed the same pattern. Commercialization of university patents is controversial, since depending on the legal system, patents can either belong to universities or to the researchers. Also, university patents usually are results of publicly funded research so there is a debate as to whether it is acceptable to privately appropriate the returns of public investment.

CONCLUSION

The absence of common IPR law means that companies need to protect their IPR in different regions and even in different countries, which is a luxury for small companies. IPRs, therefore, are only valuable when companies have means to monitor infringement and take the required legal actions. Attempts are now being made by the regulatory authorities to ensure that IPR serve their original purpose of encouraging innovation. For instance, the Adelphi Charter was created in 2005 to address the ever-expanding nature of intellectual property (IP), which puts the future

development of creativity and innovation under question.

By establishing a culture of identifying, cultivating, and strategically using their IP assets, companies can increase their revenue, have an edge over their competitors, and position themselves well in the market. A company, however, should focus their resources on inventing, rather than litigating over their innovation, as IP is a necessary but not sufficient ingredient for a company's success.

Voice of the Customer

Steven P. Gaskin, Abbie Griffin, John R. Hauser, Gerald M. Katz, and Robert L. Klein

DEFINITION

The *Voice of the Customer* (VOC) is a term used in business to describe the process of capturing customers' requirements. The VOC is a product-development technique that produces a detailed set of customer wants and needs, which are organized into a hierarchical structure, and then prioritized in terms of relative importance and satisfaction with current alternatives.

The VOC process has important outputs and benefits for product developers. VOC provides

- a detailed understanding of the customer's requirements
- a common language for the team going forward
- key inputs for the setting of appropriate design specifications for the new product or service
- a highly useful springboard for product innovation.

There are four aspects of the VOC – customer needs, a hierarchical structure, priorities, and customer perceptions of performance.

DESCRIPTION AND COMMENTARY

VOC studies typically consist of both qualitative and quantitative market-research steps. They are generally conducted at the start (or “fuzzy front end”) of any new product, process, or service design initiative to better understand the customer's wants and needs (*see* FRONT END OF INNOVATION). The VOC can also be a key input for new-product definition, QUALITY FUNCTION DEPLOYMENT (QFD), or the setting of detailed design specifications (*see* PRODUCT SPECIFICATIONS). It is critical that the product development core team own and be highly involved in this process. They must be the ones who take the lead in defining the topic, designing the sample (i.e., the types of customers to include), generating the questions for the dis-

cussion guide, either conducting or observing and analyzing the interviews, and extracting and processing the needs statements. Only by being highly involved can the team fully internalize the VOC and make effective product-design decisions (*see* PRODUCT DESIGN).

As noted in the definition, there are four aspects of the VOC – customer needs, a hierarchical structure of the needs, priorities, and customer perceptions of performance.¹

Customer needs. A customer need is a description, in the customer's own words, of the benefit to be fulfilled by the product or service. For example, when describing diagonal lines on a computer monitor, a customer might want them “to look like straight lines with no stair-step effect.” Note that *the customer need is not a solution*, such as a particular type of monitor (XGA, Megapixel, flat screen, flat panel, etc.), nor a physical measurement (number of noticeable breaks in the line), but rather a detailed description of how the customer wants images to appear on the monitor (Griffin and Hauser, 1993).²

The distinction between physical measurements and customer needs has proven to be one of the keys to the success of marketing tactics. As illustrated in Figure 1, the “lens” model suggests that customers see the world through the lens of their perceptions (their needs) (Brunswick, 1952). The lens model says that customers choose (buy a product or service) if they prefer that product over others and it is available to them in the marketplace. However, preferences are based on how customers perceive the world. This perception may or may not be totally accurate. It is based, of course, on the product's features, but it is also based on the image created by advertising, packaging, word of mouth, social context, and so on. Marketing is an integrated activity that attempts to design the product (physical features) and the marketing to influence customer perceptions. Within the context of the lens model, the VOC identifies the dimensions of customer value (customer needs) and how customers form preferences with respect to those needs (importance of those customer needs). The VOC might also identify how advertising, and so on, affect perceptions, availability, and perceived price.

Figure 1 The lens model of customer choice.

Knowing customer needs is critical to both product development and marketing. For example, if a product-development team focuses too early on solutions, they might miss creative opportunities. A computer-monitor team might be tempted to focus on the size of the monitor or the shape. However, readability might also depend on the ambient room light and reflections, the colors that the software designer chooses, the ratio of the height of small letters to that of capital letters, and even the style of the typeface (serif or sans serif, proportional or fixed, etc.). All of these design attributes interact with the size and shape of a monitor to affect the customer need of “easy-to-read text.” Some may be less costly and more effective, some may be synergistic with changing the monitor’s size and shape, but all should be considered before a final design is chosen for the monitor.

Discussions with customers usually identify 75–150 phrases that might be considered an articulation of customer needs. Such phrases might include basic needs (what a customer assumes a monitor will do), articulated needs (what a customer will tell you that he, she, or they want a monitor to do), and exciting needs (those needs which, if they are fulfilled, would delight and surprise the customer) (*see also* KANO MODEL OF CUSTOMER SATISFACTION). It is extremely important that these customer needs be stated *in the customers’ own words*, and not in industry or company jargon, in order to not lose the meaning.

Identifying customer needs is primarily a qualitative research task. In a typical study, between 10 and 30 customers are interviewed for approximately one hour in a one-on-one setting. For example, a customer might be asked to picture him- or herself viewing work on a

computer. As the customer describes his or her experience, the interviewer keeps probing, searching for better and more complete descriptions of how he or she views data, images, video, or anything else, how he or she works with those images, working conditions, ambient lighting, and so on. The goal is to experience the experience of the customer. Sometimes, the interviews take place at the site where the customer uses the product – for example, VOC interviews have been conducted on oil-drilling platforms for manufacturers of oil-drilling equipment. This method of data collection is sometimes referred to as *customer visits* (McQuarrie, 2008), *contextual inquiry*, or *ethnography*.

The interviews are called “*experiential*,” because they focus on the customers’ experiences. In the interview, the customer might be asked to voice needs relative to a number of real experiences. The interview ends when the interviewer feels that no new needs can be elicited from that customer.

While it is tempting to simply ask customers, “What are your needs?” customers often have difficulty articulating them. It is much better to infer customer needs from experiential interviews or observation.

Hierarchical structure. The average marketing manager cannot work directly with the 75–150 detailed customer needs found in the first step of the VOC process. A simpler structure is needed that focuses both strategy and tactics. The “Voice of the Customer” structures customer needs into a hierarchy of primary, secondary, and tertiary needs. *Primary needs*, also known as *strategic needs*, are the 2–10 top-level needs that are used by the team to set the strategic direction for marketing. Each primary need is elaborated

into 3–10 secondary needs. *Secondary needs* indicate more specifically what the marketing manager must do to satisfy the corresponding primary (strategic) need. (Secondary needs are also known as *tactical needs*.) *Tertiary needs*, also known as *operational* or *detailed needs*, provide greater detail so that engineering, R&D, and, perhaps, the advertising agency, can develop a detailed set of product characteristics or advertising copy that satisfies the primary and secondary needs.

For example, a VOC analysis for movie theaters identified the following 17 secondary (tactical needs) structured into 6 primary (strategic needs):

- Theater selection
 - Offers a good selection of movies and show times
 - Easy to get information about show times
 - I can always get into the movie I want to see
 - A variety of easy and economical ways to buy tickets
- Getting to the theater
 - The theater is conveniently located
 - There is safe, convenient parking
- Food/refreshments
 - Good food is available at a fair price
 - Concessions are well run
- The theater building
 - Quick and easy access to everything I need
 - Handles crowds well
 - Friendly and available customer service
 - Clean, well-equipped restrooms
 - A comfortable feeling inside the theater
- Inside the theater auditorium
 - Clean, comfortable seating
 - Auditoriums are clean
- The movie experience
 - A great view and sound so I'm right in the action
 - No disturbances during the show.

There are a number of ways to group the 75–150 tertiary (operational) needs into a more aggregate set of tactical needs, and then further into an even smaller set of strategic needs. The easiest way is to have the product-development

team do so as a group. However, while convenient, this approach has the important limitation that the results tend to reflect the company's organizational chart, that is, how the product is developed and produced, rather than the way customers think. It is far better to have customers group the needs. One way this can be done is through the use of one or a few focus groups. A moderator guides the process and makes sure the groupings make sense and are sufficiently disaggregate (i.e., that there are sufficiently many tactical needs so that they do not cover multiple topics). A more statistically representative method is to survey a random sample of current and potential customers and have them sort the needs individually into piles based on similarity. This results in a co-occurrence matrix, which can be analyzed using a hierarchical clustering routine. The output is a dendrogram, which shows how the needs should be grouped for any total number of needs, from the total number of detailed needs down to two or more strategic needs. The final number of primary and secondary needs are then determined judgmentally on the basis of the output of the cluster analysis.

Priorities. Some needs have higher priorities for customers than others. The marketing manager uses these priorities to make decisions that balance the cost of fulfilling a customer need with the desirability (to the customer) of fulfilling that need. For a movie theater company, for example, the strategic decision on whether to provide or communicate improved movie-viewing experience depends upon the cost and feasibility of improving the experience and the priority to the customer of an improved viewing experience relative to the customer's other needs. In the VOC, these priorities apply to perceived customer needs rather than product features or engineering solutions. As an example, a quantitative survey of people who go to movie theaters yielded the following importance weights for the 17 secondary needs (Figure 2).

A number of new techniques have been developed recently to prioritize customer needs. One, called *teaching agents to choose*, is an incentive compatible direct-elicitation technique.³ During the survey, respondents

Figure 2 Importance ratings for movie theater needs.

give instructions to a hypothetical “agent” about what rules to use when deciding to choose which product to buy. Priorities of the needs can be estimated by tallying the frequency of mention of the needs referenced in these rules. Another technique, MaxDiff, involves an exercise where respondents pick the most and least important of a series of subsets of needs. The resulting scores are not subject to scale usage bias, which can lead to problems, particularly in international studies.

Customer perceptions of performance. Customer perceptions are also derived from quantitative market research about how customers perceive the performance of products that compete in the market being studied. If no product exists as yet, the perceptions indicate how customers now fulfill those needs. (For example, existing

patterns of medical care serve as generic competition for health-maintenance organizations. Automobile and bus transportation serve as generic competition for Southwest Airlines.) Knowledge of which products fulfill which needs best, how well those needs are fulfilled, and whether there are any gaps between the best product and “our” existing product provide further input into marketing decisions.

Customer perceptions are often displayed via a “snake plot,” called so because each product’s performance “snakes” across the page. These data are often obtained via a questionnaire in which each respondent rates each product (that they consider) on each of the secondary customer needs.

For example, when people who go to movie theaters were asked to rate how well the theater they attend most often performed on

Figure 3 Performance ratings for movie theaters.

the secondary needs, we obtained the plot in Figure 3.

EXAMPLES OF VOC’S ROLE IN PRODUCT DEVELOPMENT

During a VOC for the renal division of Baxter Healthcare, users expressed a need to quickly understand the nature and seriousness of the various alarms that typically sounded throughout the day. The product’s designers developed a traffic-light device with colored lights that indicated the gravity of the problem at a glance.

A few years ago, Intel, the world’s largest manufacturer of microprocessors, embarked on a very public strategy to develop specialized microprocessors for various applications. To

better understand customer needs surrounding these applications, the company began to develop its own VOC. Using a combination of ethnography and sit-down interviews, followed by group affinity processes and large-scale quantitative prioritization surveys, the company has now conducted more than 20 such studies on a host of topics, ranging from extremely simple consumer applications, to highly advanced applications with IT Directors at very large companies.

One of the most compelling products to emerge from this strategy is the v-Pro™ micro-processor for business desktop computers. The v-Pro™ technology addresses a number of critical problems for IT Directors who must manage a large “fleet” of company computers, and

ensure their security from external corruption and tampering. The v-Pro™ offers several new features – which have proven to be extremely attractive to IT Directors – that emerged from the identification of key unmet needs in the VOC process. Launched in mid-2006, the v-Pro™ became the fastest product in Intel's history to exceed \$1 billion in revenue.

PPG Industries, a leading manufacturer of industrial coatings and other commercial materials, trained product development teams across most of its major divisions in the use of VOC. These teams then conducted a number of highly successful VOC studies throughout the world, on topics as diverse as applications for polyurethane coatings, auto paint used in body shops, and eco-friendly uses for fiberglass. Products that emerged from these applications include a chemical-agent-resistant coating used in military applications, a new material used for golf-ball covers, and an advanced fiberglass product used in wind-power generation. This latter product allowed PPG to acquire a major share of this rapidly expanding industry.

As may be seen in these examples, gathering the VOC is an extremely important part of the “fuzzy front end” of the new-product development process. It forms a solid basis for design and marketing decisions from concept development through product launch.

ENDNOTES

¹ The Voice of the Customer has its origins in the QFD process, where it is used to develop the customer needs that are linked to performance

measures. This is why the definition used here is narrower than the generic use of VOC, which can refer to customer feedback in any form. See Griffin and Hauser (1993).

² Much of the material used here is drawn from an MIT Sloan Courseware document by John R. Hauser, “*Note on the Voice of the Customer*,” MIT, Cambridge, MA 2008. MIT Sloan grants the nonexclusive right to use this material. MIT Sloan retains a nonexclusive right to this material.

³ “Incentive compatible” means the incentives for survey respondents are set up in a way that they benefit most from responding in a desired way (in this case, telling the truth).

success factors for new-product development

Robert G. Cooper and Elko J. Kleinschmidt

INTRODUCTION

Product innovation – the development of new and improved products – is crucial to the survival and prosperity of the modern corporation. New products currently account for up to 33% of company sales (Griffin, 1997; American Productivity & Quality Center, 2003), while product life cycles (*see* PRODUCT LIFE CYCLE; TAKEOFF) are getting shorter: a 400% reduction over the last 50 years, the result of an accelerating pace of product innovation. But many products do not succeed: approximately one in ten product concepts succeeds commercially and only 51% are launched on time (American Productivity & Quality Center, 2003). Further, only one in four development projects is a commercial success (Cooper, 2001), while companies scrap almost one-third of new-product projects incurring losses of \$80 billion annually.

The huge amounts at stake coupled with the high odds of failure make product innovation one of the riskiest endeavors of the modern corporation. Thus many managers, researchers, and pundits have sought answers to the age-old question: what makes a new product a winner? And why are some businesses so much more successful at product development than the rest?

We look at the critical success factors that distinguish new-product winners. These factors are based on studies that focus on individual new-product projects (factors 1–7 below); and also on studies that assess the business's overall new-product performance (factors 8–13 below).

WHAT MAKES NEW PRODUCTS SUCCESSFUL

Factor 1: A unique superior product. A superior and differentiated product is the number one driver of success and profitability, with success rates reported to be three to five times higher than for “me too,” reactive products (Cooper, 2001; Cooper and Kleinschmidt, 1996). Well-known studies (NewProd Studies by Cooper *et al.*, *see* Cooper, 2001) show the dramatic impact of product superiority: For example, such products (the top 20%) when compared to those with

the least degree of differentiation (the bottom 20%)

- have an exceptional commercial success rate of 98.0%, versus only 18.4% for undifferentiated ones;
- have a market share of 53.5% of the defined target market, versus only 11.6% for “me too” new products;
- have a rated profitability of 8.4 out of 10 (versus only 2.6 out of 10 for undifferentiated products; here 10 = exceptional profits, far exceeding the company's minimum hurdle);
- meet company sales and profit objectives to a greater degree than do undifferentiated products.

The same studies show, however, that reactive products, undifferentiated products, and technically driven products that lack customer benefits are the rule rather than the exception; and the majority fail.¹

What do these superior products with unique customer or user benefits have in common? These winning products

- feature good value for money for the customer, reduce the customer's total costs (high value in use), and boast excellent price/performance characteristics;
- provide excellent product quality relative to competitors' products, in whatever manner the user measures quality (*see* COMPETITIVE ADVANTAGE);
- are superior to competing products in terms of meeting users' needs, offer unique features not available on competitive products, or solve a problem the customer has with a competitive product;
- offer product benefits or attributes easily perceived as useful by the customer, and benefits that are highly visible (*see* VALUE PROPOSITION).

Note that the product must be superior in the eyes of the customer, not just the eyes of the engineer, scientist, or designer: often developers heavily overestimate the customer benefits and desirability of their products (Cooper, Edgett, and Kleinschmidt, 2003).

2 success factors for new-product development

Factor 2: A strong market orientation – market driven, customer focused. A thorough understanding of customers' needs and wants, the competitive situation, and the nature of the market is an essential component of new-product success (see VOICE OF THE CUSTOMER). This finding is supported in virtually every study of product success factors (Cooper, 2001). Recurring success themes include

- need recognition
- understanding user needs
- market-need satisfaction
- constant customer contact
- strong market knowledge and market research
- quality of execution of marketing activities
- more spending on the up-front marketing activities.

Even in the case of technology-driven new products (where the idea comes from a technical or laboratory source), the likelihood of success is greatly enhanced if customer and marketplace inputs are built into the project soon after its inception.

Conversely, a failure to adopt a strong market orientation in product innovation, an unwillingness to undertake the needed market assessments and to build in the Voice of the Customer, and leaving the customer out of product development spell disaster. Poor market research, inadequate market analysis, weak or no market studies, test markets, and market launch, and inadequate resources devoted to marketing activities are common weaknesses found in almost every study of why new products fail (Cooper, 2001).

A strong market orientation must be built into every stage of the new-product process to achieve success (Cooper, 2001):

- *Idea generation:* focusing on the customer, and using the customer as a source of ideas (see IDEA MANAGEMENT).
- *Product design:* employing market research as an input to product design, not just an after-the-fact check (see PRODUCT DESIGN).
- *During development:* maintaining constant customer contact and feedback (e.g.,

continuous customer testing of facets of the product) (see PRODUCT TESTING).

- *After development:* undertaking customer trials, preference tests, and test markets to verify market acceptance and launch plan (see PRETEST MARKET MODELS).
- *Launch:* employing a well-designed, carefully targeted, properly resourced launch, guided by a well-conceived marketing plan based on solid market information (see LAUNCH STRATEGIES).

Factor 3: The world product – a global orientation in product development. The world is the business arena today, and thus company growth and profitability are dependent on strategies of globalization and new-product development (see GLOBAL PRODUCT DEVELOPMENT). In global markets, new-product development plays a primary role in achieving a sustainable competitive advantage (Kleinschmidt, de Brentani, and Salome, 2007).

A recent study found that multinational firms that take a global approach to new-product development outperform those that concentrate their research spending in their home market (The Economist, 2008, November 22–28, p. 74). Further, an investigation by de Brentani and Kleinschmidt (2004) and Kleinschmidt, de Brentani, and Salome (2007) also showed that firms that are strongly globally minded in their new-product development perform significantly better. International products targeted at world and nearest-neighbor export markets are the top performers (Cooper, 2001). By contrast, products designed for only the domestic market, and sold to domestic and nearest-neighbor export markets fare more poorly. The magnitude of the differences between these international and exported new products versus domestic products is striking: differences of two- or three-to-one on various performance gauges.

Increasing globalization of markets demands global products. To define the new-product market as “domestic” and perhaps a few other “nearby convenient countries” severely limits market opportunities. For maximum success in product innovation, the objective must be to design for the world and market to the world. Sadly, this international dimension is an often

overlooked facet, or one which if included, is handled late in the development process or as a side issue (*see also* LOCALE OF INNOVATION).

An international orientation means defining the market as an international one, and designing products to meet international, not just domestic, requirements. The result is either a global product (one version for the entire world) or a glocal product (one development effort, one product concept or platform, but perhaps several product variants to satisfy different international markets). An international orientation also means undertaking market research, concept testing, and product testing in multiple countries, rather than just the home country; and it means relying on an international or global project team (only one new-product project team in five is reported to be a global development team) (Cooper, 2001).

Factor 4: Predevelopment work – the up-front homework. The steps that precede the design and development of the product make the difference between winning and losing (Cooper, 2001). New-product projects that feature a high quality of execution of activities that precede the development phase – the fuzzy front end – are more successful:

- a success rate of 75.0% (versus only 31.3% for projects where the predevelopment activities are found lacking);
- a higher rated profitability (7.2 out of 10 versus only 3.7 for projects where predevelopment activities are poorly undertaken);
- a market share of 45.7% (versus 20.8%) (Cooper, 2001).

Successful businesses spend about twice as much time and money on these vital up-front or predevelopment activities, such as initial screening, preliminary market and technical assessments, detailed market studies or marketing research (success factor 2), and business and financial analysis just before the decision to “Go to Development” (Cooper, 2001).

Most businesses confess to serious weaknesses in the up-front or predevelopment steps of their new-product projects. Small amounts of time and money are devoted to these critical steps:

only about 7% of the project’s expenditure and 16% of the effort. Far from adding extra time to the project, research reveals that homework pays for itself in reduced development times, the result of sharper and more stable product definition, and fewer surprises (and time wasters) later in the project (Cooper, 2001).

Factor 5: Sharp and early product definition.

Successful products have much sharper definition prior to development. Products that have these sharp definitions are 3.3 times as likely to be successful and have higher market shares (by 38 share points on average); they are much more profitable than poorly defined products, and they meet company sales and, more so, profit objectives (Cooper, 2001).

This definition includes

- specification of the target market: exactly who the intended users are;
- description of the product concept and the benefits to be delivered;
- delineation of the positioning strategy (including the target price) (*see* PRODUCT POSITIONING);
- and a list of the product’s features, attributes, requirements, and specifications (*see* PRODUCT SPECIFICATIONS).

Unless these four items are clearly defined, written down, and agreed to by all parties prior to entering the development stage, the odds of failure increase by a factor of 3, for the following reasons (Cooper, 2001):

- Building a definition step into the new-product process forces more attention to the up-front or predevelopment activities.
- The definition serves as a communication tool and guide. All-party agreement or “buy in” means that each functional area involved in the project has a clear and consistent definition of what the product and project are, and is committed to it.
- This definition also provides a clear set of objectives for the development phase of the project, and the development team members. With clear product objectives, development typically proceeds more efficiently and quickly: there are no moving goalposts and no fuzzy targets.

4 success factors for new-product development

Factor 6: The way project teams are organized. Product innovation is very much a team effort. On doing a post mortem on any bungled new-product project, invariably one will find each functional area doing its own piece of the project, with very little communication between players and functions – a fiefdom mentality; and no real commitment of project team members to the project. Many studies concur that how the project team is organized and functions strongly influences project outcomes (*see also ORGANIZING FOR INNOVATION*).

Product development must be run as a multi-disciplinary, cross-functional effort (*see also CROSS-FUNCTIONAL TEAM*). Good organizational design means projects that are

- organized as a cross-functional team with members from R&D, engineering, marketing and sales, operations, and so on (as opposed to each function doing its own part independently);
- where the team is dedicated and focused (i.e., devotes a large percentage of their time to this project, as opposed to spread over many projects or other work);
- where the team members are in constant contact with each other, via frequent but short meetings, interactions, project updates, and even colocation;
- where the team is accountable for the entire project from beginning to end (as opposed to accountability for only one stage of the project);
- where there is a strong project leader or champion who leads and drives the project (*see also LEADERSHIP ROLES IN PRODUCT DEVELOPMENT*).

While the ingredients of good organizational design should be familiar, surprisingly, many firms have yet to get the message (American Productivity & Quality Center, 2003; Cooper and Kleinschmidt, 1996).

Factor 7: Leveraging core competencies. Leverage and synergy is the common thread that binds the new business to the old. When translated into product innovation, the ability to leverage existing and in-house strengths, competencies, resources, and capabilities increases the odds of

success of the new-product project (*see CORE COMPETENCIES*). By contrast, “step-out” projects take the firm into territory that lies beyond the experience and resource base of the company, and increase the odds of failure (Cooper, 2001).

The reasons for the impact of leverage are clear:

1. Resources are available and at marginal cost.
2. Operating within one’s field of expertise – either familiar markets or familiar technologies – provides considerable “domain knowledge,” which is available to the project team.
3. The more often one does something, the better one becomes at doing it – the experience factor. If new-product projects are closely related to (leveraged from) current businesses, the chances are, there has been considerable experience with such projects in the past, hence lower costs of execution and fewer misfires.

Two types of leverage are important to product innovation:

- *Technological leverage:* the project’s ability to build on in-house development technology, use inside engineering skills, and use existing manufacturing or operations resources and competencies.
- *Marketing leverage:* project/company fit in terms of customer base, sales force, distribution channels, customer-service resources, advertising and promotion, and market-intelligence skills, knowledge, and resources.

These two dimensions of leverage – technological and marketing, and their ingredients – become obvious checklist items in a scoring or rating model to help prioritize new-product projects. If leverage is low, yet the project is attractive for other reasons, then steps must be taken to bolster the internal resources and competencies. Low leverage scores signal the need for outside resources – partnering or outsourcing. But neither solution is a panacea: there are risks and costs to both routes to securing the needed resources and competencies (Campbell and Cooper, 1999).

Innovation versus incremental product development. The term *new products* encompasses a wide range of development projects, from product improvements to true innovations (see INNOVATION TYPOLOGIES). Note that most “new products” are not truly new to the world products or breakthroughs (see RADICAL INNOVATION); rather they are incremental innovations such as cost reductions, improvements, product-line extensions, and new items in existing product lines. Such incremental products, often called *sustaining innovation*, are necessary to keep the firm’s product portfolio current and competitive, and are based on exploiting existing company knowledge, markets, and customers; not surprisingly, they represent the great majority (approximately 90%) of all new projects (Cooper, 2001; Cooper, Edgett, and Kleinschmidt, 2003).

Seeking success by applying some of these seven success factors above could lead to a “success trap.” For example, accumulated decision-making experiences will favor incremental projects over true innovations (March, 1991; Levinthal and March, 1993; Teece, Pisano, and Shuen, 1997). Additionally, rigorously applying factors 2, 5, and 7 – a strong market orientation, seeking sharp, early product definition, and leveraging core competencies – could lead to picking closer-to-home and less risky development projects. Thus, employing factors 1–7 will certainly increase new-product success rates, but some factors, when made difficult to achieve real breakthroughs that are aimed at new markets, may require new technical and market knowledge; these factors are typically difficult to define in the early stages. The result could be high success rates, but lower overall new-product performance for the firm – a “win the battle, but lose the war” outcome.

WHAT DISTINGUISHES THE TOP-PERFORMING BUSINESSES

A number of success factors have been uncovered by research into what makes some businesses more successful at product innovation. Factors 8–13 below are some of the more important factors that separate the top-performing businesses from the rest in product development.

Factor 8: The right organizational culture.

There is ample research-based evidence that a strong innovation culture has a positive impact on performance. Characteristics of this culture include (de Brentani and Kleinschmidt, 2004; Kleinschmidt, de Brentani, and Salome, 2007)

- managers and employees that believe in the importance of new products for the company’s continued success, domestically and internationally;
- a mind-set that motivates employees to holistically endorse a belief in creating newness;
- company behavior that is comfortable with, even aggressive about, new ideas, change, risk, and failure;
- an atmosphere where entrepreneurship and risk taking are encouraged and rewarded;
- individuals or teams that are not inadvertently punished when new products do not achieve expected results;
- openness and informal communication and involvement, thinking outside the box, and adaptability to change, as preferred modes of operation.

The best companies in the APQC best practices study (2003) emphasize employee recognition for new-product performance (Griffin, 2008). A positive culture also means senior managers refraining from “micro-managing” projects and second-guessing project team members; and resources and time being made available for creative people to work on their own “unofficial projects,” for example, via free scouting-time or bootstrapping funds; and permitting skunk works projects outside the official bureaucracy. Idea-submission schemes (where employees are encouraged to submit new product ideas), and open project review meetings (where the entire project team participates), are other facets of a positive climate (Cooper, Edgett, and Kleinschmidt, 2003). Most businesses, however, are quite weak on almost all these ingredients of a positive culture or climate, with typically less than one-third of businesses employing these practices. By contrast, top-performing businesses embrace these practices to a greater extent.

6 success factors for new-product development

Factor 9: A product innovation and technology strategy for the business. We live in turbulent times. Technology advances at an ever increasing pace; customer and market needs are constantly changing; competition moves at lightning speed; and globalization brings new players and opportunities into the game. More than ever, businesses need a product innovation and technology strategy to help chart the way (Cooper, 2000) to achieve success (de Brentani, Kleinschmidt, and Salomo, 2009).

Having a new-product strategy for the business is strongly linked to positive performance (American Productivity & Quality Center, 2003). Top-performing businesses in product development clearly define new-product goals for the business; for example, what percentage of the business's sales, or profits or growth will come from new products (*see also OPPORTUNITY IDENTIFICATION*). And the role of product innovation in achieving overall business goals is clearly articulated. Most important, an innovation strategy has a longer time horizon and commitment; surprisingly, only 38.1% of businesses having a longer term new-product strategy, but most top performers do (American Productivity & Quality Center, 2003).

Top-performing businesses focus their R&D efforts by delineating strategic arenas: strategic areas on which the business will concentrate its new-product efforts (*see RESEARCH & DEVELOPMENT*). Defined arenas might include industry sectors, specific markets, product types, or technology types.

Strategic buckets is a method applied by top performers to ensure strategic alignment of product innovation with business goals (*see PORTFOLIO MANAGEMENT*). The strategic-buckets method dedicates resources (funds or person days) to different project types, for example, incremental versus innovative projects, or across strategic arenas, thereby fostering the right mix and balance of development projects.

Finally, strategic product road maps are also employed by top performers. A road map is simply a management group's view of how to get where they want to go or how to achieve their desired objective. The road map portrays a series of major development initiatives – product

and technology developments – sequenced over time, typically five to seven years into the future.

Factor 10: Resource commitment. Too many projects simply suffer from a lack of time and money commitment. The results are predictable: much higher new-product failure rates (Cooper, 2001; Cooper and Kleinschmidt, 1996) and poorer new-product performance for the business overall (de Brentani and Kleinschmidt, 2004). Some facts, in this context, are listed below:

- A strong market orientation is missing in the typical new-product project; and much of this deficiency is directly linked to a lack of marketing resources available for the project.
- Another serious pitfall is that the front-end homework does not get done. Again much of this deficiency can be directly attributed to a lack of resources: simply not enough money, people, and time to do the work.

The reason is that as the competitive situation has toughened, companies have responded with restructuring and doing more with less. Consequently, resources are limited or cut. This short-term focus takes its toll. Certain vital activities, such as market-oriented actions and predevelopment homework are highly under-resourced, particularly in the case of product failures.

Best-practice companies commit the necessary resources to new products much more than do most firms (American Productivity & Quality Center, 2003; de Brentani and Kleinschmidt, 2004). While product development resources are in short supply across the board – with less than 30% of businesses indicating “sufficient resources” from four key functional areas – top-performing businesses appear to be much better resourced. Equally important, these resources are focused and dedicated, with project team members not working on too many projects or doing other tasks. Indeed, about half the top performers have a ring-fenced product innovation group that does nothing but work on new products (this is a dedicated cross-functional group – technical, marketing, even sales and operations – whose full-time job is to work on new-product projects, and which typically

reports to a senior executive). Finally, resources are available early in the project to undertake the essential up-front homework and early-stage market research outlined above.

Factor 11: Top management support. Top management support is a necessary ingredient for product innovation and is directly linked to the business's performance in product development (Cooper, 2001; de Brentani and Kleinschmidt, 2004; Kleinschmidt, de Brentani, and Salome, 2007). But it must be the right kind of support. The top management's role in product development is as a facilitator – to set the stage – and not as an actor, front and center.

One important role of senior management is to lead the innovation effort in their business. In other words, they articulate a new-product strategy for the business, something that is often missing. Management in top-performing businesses also commits the necessary product development resources, and keeps the commitment (American Productivity & Quality Center, 2003). They support a disciplined process to drive products to market. These three factors – an articulated new-product strategy, adequate resources, and a disciplined new-product process – are the strongest drivers of a business's new-product performance (Cooper, 2001; Cooper and Kleinschmidt, 1996).

The senior management has a major impact on and fosters a positive climate and culture for innovation within the business, supporting innovative activities and projects at every opportunity with actions, not just words. Finally, the senior management empowers project teams and supports committed champions by acting as mentors, facilitators, “godfathers,” or executive sponsors to project leaders and teams – acting as “executive champions.”

Factor 12: Tough Go/Kill decision points and better focus (portfolio management). Most companies suffer from too many development projects and not enough resources to mount an effective or timely effort on each, that is, there is a lack of focus. This stems from inadequate project evaluation and poor project prioritization. Project evaluations are consistently cited as weakly handled or nonexistent: decisions involve the wrong people from the

wrong functions (no functional alignment); no consistent criteria are used to screen or rank projects; or there is simply no will to kill projects at all (Cooper, Edgett, and Kleinschmidt, 2001; Cooper and Kleinschmidt, 1996).

The desire to weed out bad projects coupled with the need to focus limited resources on the best projects means that tough Go or Kill and prioritization decisions must be made. Some companies have built funnels into their idea-to-launch process via a number of decision points in the form of gates. At successive gate reviews, the senior management rigorously scrutinizes projects, makes Go or Kill and prioritization decisions based on visible Go/Kill criteria, and culls out the weaker or less-valuable projects.

Project selection and picking winning new-product initiatives is only part of the task, however. Other goals are selecting the right mix and balance of projects in the development portfolio, seeking strategic alignment in the portfolio, and ensuring that the business's development spending mirrors its strategic priorities. Many businesses have moved to more formal portfolio management systems (*see* PORTFOLIO MANAGEMENT) to help effectively allocate resources and prioritize new-product projects (Cooper, Edgett, and Kleinschmidt, 2001).

A vital issue in portfolio management is achieving the right mix and balance of development projects in the portfolio. Development portfolios in top-performing businesses contain a higher proportion of more innovative development projects, while portfolios in the typical firm have far too many low-value, noninnovative projects. To foster more innovative development projects, top-performing businesses articulate a product innovation strategy that specifies the quest for true innovations (success factor 9) (American Productivity & Quality Center, 2003). They set aside sufficient resources for innovative development work via strategic buckets – PORTFOLIO MANAGEMENT outlines how to achieve the correct balance between riskier, longer-term and more innovative development projects versus shorter-term, incremental innovations. Additionally, the top management supports such innovative projects and is not afraid to invest in riskier developments

(success factor 11). Finally, top-performing businesses employ flexible development or idea-to-launch processes that accommodate more innovative products, or have adopted quite different processes for such high-risk projects (Cooper, 2006) (THE STAGE-GATE IDEA TO LAUNCH SYSTEM deals with the issue of adaptive, scalable, and flexible development processes in more detail).

Factor 13: A multistage, disciplined new-product process. A systematic new-product process – a Stage-Gate® system² – is the solution that many companies have turned to in order to overcome the deficiencies that plague their new-product programs (Cooper, 2001). A Stage-Gate® process is simply a road map or “play book” for driving new products from idea to launch, successfully and efficiently. For major projects, the system consists typically of five stages from Discover through to Launch, with critical best-practice activities laid out for the project team to execute within each stage. Each stage is preceded by a gate or Go/Kill decision point, where an investment decision is made to continue with the project, or to cut one’s losses and kill a bad project.

Almost every top-performing company has implemented such a stage-and-gate system to drive their new-product projects through to commercialization, according to the APQC benchmarking study (2003). The payoffs of such processes have been frequently reported: improved teamwork, less recycling and rework, improved success rates, earlier detection of failures, a better launch, and even shorter cycle times (by about 30%) (see THE STAGE-GATE IDEA TO LAUNCH SYSTEM for the details on the idea-to-launch or Stage-Gate® process).

CONCLUSION

Product innovation is a vital task for the modern corporation. The company’s success at new-product conception, development, and launch may well decide the fate of the entire business. But many companies miss the mark when it comes to the 13 critical success factors outlined in this article, and the results are predictable – a mediocre new-product effort. These success factors are fact based and

proven, and when implemented proficiently, lead to higher success rates at the new-product project level and a higher overall new-product performance for the business.

front end of innovation

Peter Koen and Heidi Bertels

DEFINITIONS – WHAT IS THE FRONT END AND WHY IS IT IMPORTANT?

Innovation in large firms may be divided into three parts: front end, new-product development (NPD), and commercialization. Most research activities have focused on the NPD part (see Brown and Eisenhardt (1995) and Montoya-Weiss and Calantone (1994) for reviews), which requires a well-practiced routine and which has become regimented through the use of Stage-Gate™ (Cooper, 2001), total quality management, and six-sigma programs. The front end is typically thought of as consisting of the first three sequential stages of the Stage-Gate™ process with the remaining stages focusing on the development process. The first of these three stages is discovery, where prework is done to understand the market and generate ideas. The second stage, scoping, consists of rudimentary assessments of the market; and evaluation of the technical merits of the project. And the third stage, building a business case, focuses on more detailed investigation leading to a business case (see also THE STAGE-GATE IDEA TO LAUNCH SYSTEM).

More recently, Koen *et al.* (2002), Khurana and Rosenthal (1998), Langerak, Hultink, and Robben (2004), and Bertels, Koen, and Kleinschmidt (2008) have taken a more holistic view of the front end (Figure 1), which includes both organizational resources and front-end routines. Organizational resources consist of vision, strategy, resources, and climate that set the stage for the front-end routines; these, in turn, are opportunity recognition, idea generation, and concept definition. This module adds to Cooper's (2001) traditional Stage-Gate™ model by taking into account the organizational resources that lay the foundation for the front-end routines and by emphasizing the iterative nature of the front end where new learning in one of the routines can affect the activities in the others.

The front end is important because the product-development process is path dependent. This means that choices made in the

front end lead to options as well as limitations regarding which products a company will ultimately be able to develop. The front end is also fundamentally different from the development portion of the innovation process (Table 1). Essentially, the front end requires more expansive and divergent thinking, whereas the NPD thrives under sequential, well-practiced routines. As a result, the management process in the front end is different from the one for the development part of the innovation process.

The front end of innovation is also referred to as the *fuzzy front end* or *predevelopment* in the academic literature. The term *front end of innovation* was first used by Koen *et al.* (2002) with the purpose of replacing the more accepted and expressionistic “fuzzy front end” first coined by Reinertsen (1985). The reasoning behind the wish to abandon the term *fuzzy front end* is that the word “fuzzy” implies that the front end is mysterious, lacks accountability, and cannot be critically evaluated. The term *front end of innovation* has gained popularity over “fuzzy front end,” mostly driven by a popular practitioner conference, the “Front End of Innovation,” started in 2003 and held annually.

Our discussion is divided into four sections consistent with the holistic model (Figure 1). The next section provides a definition of the organizational resources and related empirical work. The following three sections define and discuss each of the front-end routines for innovation which are, respectively, (i) exploitative, (ii) explorative but leveraging the firms' established value network, and (iii) explorative, requiring a new value network (Christensen and Rosenbloom, 1995; March, 1991). Exploitative efforts concern incremental activities, whereas explorative efforts refer to more radical or breakthrough efforts.

ORGANIZATIONAL RESOURCES

Organizational resources define the boundary conditions for the front-end routines. Vision, which essentially is the precursor to all of the front-end activities, is distinct from strategy. Whereas strategy provides an investment road map to innovation initiatives; a company's vision describes a future state. For example, Apple Computer's vision¹ is to bring the

Table 1 Difference between the Front End of Innovation and the New-Product Development Process.

| | <i>Front end of innovation</i> | <i>New-product development</i> |
|------------------------|---|--|
| Nature of work | Experimental, often chaotic. “Eureka” moments. Can schedule work – but not invention | Disciplined and goal-oriented with a project plan |
| Commercialization date | Unpredictable or uncertain | High degree of certainty |
| Funding | Variable. In the beginning phases many projects may be “boot legged,” while others will need funding to proceed | Budgeted |
| Revenue expectations | Often uncertain with a great deal of speculation | Predictable with increasing certainty, analysis, and documentation as the product release date gets closer |
| Activity | Individuals and team conducting research to minimize risk and optimize potential | Multifunction product and/or process-development team. |
| Measures of progress | Strengthened concepts | Milestone achievement |

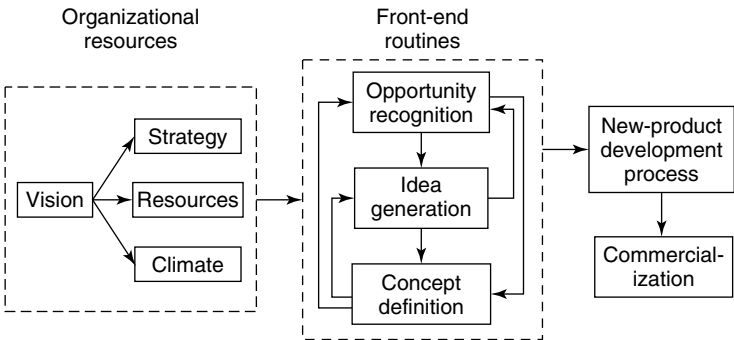

Figure 1 Holistic model of the front end.

... best personal computing and portable digital music and mobile experience to consumers, students, educators, businesses and government agencies through its innovative hardware, software, peripherals, services and Internet offerings.’ They want to accomplish this goal through “... its unique ability to design and develop its own operating system, hardware, application software and services ...” in order to bring to the customer new products and solutions “... with superior ease-of-use, seamless integration and innovative industrial design”.

In contrast, Apple’s strategy defines particular products (e.g., iPod, iPhone, and Mac Computer) and product enhancements and services (e.g., iTunes and Apple stores), which would be supported within their investment horizon. Resources, in terms of both people’s time and money, to support the front end represent a third key element. The final important element of the organizational resources that lay the foundation for the front end is the organizational climate.

The overall importance of vision and strategy to the front end is subject to controversy. Nonak

and Takeuchi (1995) assert that innovative ideas occur to individuals – not organizations; hence vision and strategy may be too confining and/or are relatively independent of innovative ideas rising from the bottom up. Burgelman (1983, p. 241) suggests in his study of internal corporate venturing that the “... autonomous strategic initiatives of individuals at the operational level of the organization ...” are critical for “... initiatives that fall outside the current concept of corporate strategy.” In contrast, Khurana and Rosenthal (1998) hypothesized the importance of a strong linkage between organizational resources and front-end routines based on their case studies. Empirical studies by Langerak, Hultink, and Robben (2004) based on the data of 126 companies in the Netherlands, and by Bertels, Koen, and Kleinschmidt (2008) based on the data of 238 companies, mostly from the United States, found strong support that vision and strategy are significantly correlated with success in the front end.

A number of studies have confirmed the importance of climate to front-end performance. Zien and Buckler (1997), in a study of 12 leading innovative companies such as Sony, Hewlett-Packard, and Toshiba, found that an innovative climate was a consistent theme across the companies that were studied. Amabile, Hadley, and Kramer (2002), in their work on creativity, also found that a climate that allows people the time to focus on a single activity for a significant part of their work day is essential to the front end. Bertels, Koen, and Kleinschmidt (2008) hypothesized and found support for a correlation between climate and resource availability in both exploitative and explorative projects.

FRONT-END ROUTINES

The three principal routines which occur in the front end are opportunity recognition, idea generation, and concept definition. Kirzner (1997) defined opportunity recognition as the recognition of an “imprecisely-defined market need or underemployed resources or capabilities.” We specifically define *opportunity* as a business or technology gap that a business realizes, by design or accident, that exists between the current situation and an envisioned

future to capture competitive advantage by responding to a threat, solving a problem, or ameliorating a difficulty. We define an *idea* as the most embryonic form of a new product or service. It often entails a high-level view of the envisioned solution needed to solve the problem identified by the opportunity. Finally, we define a *concept* as having a well-defined form including both a written and visual description, which includes its primary features and customer benefits combined with a broad understanding of the technology needed. The last stage can be equated with the completion of a business plan. We prefer the use of the term *concept* because a completed concept, with written and pictorial descriptions, allows the new product or service to enter the more routine part of the development process. We believe that these more precise definitions help overcome the potential confusion between opportunity recognition where the company identifies an unmet customer need and idea generation where specific ideas, which potentially respond to the opportunity are generated.

Kraft's development of Lay's light potato chip can be used as an example to better explain this terminology (Koen *et al.*, 2001). Kraft initially identified an opportunity to develop a low-fat product due to significant and high consumer interest in this area. On the basis of the recognition of this opportunity, they identified several methods for delivering nonfat potato chips using candidate molecules that could provide the same flavor, but would not be absorbed into the body. Several candidate nonfat molecules were developed resulting in Olestra, which is the ingredient used in the light potato chip. Olestra preserves the flavor of the potato chip without the accompanying fat content.

The holistic model (Figure 1) is not the same as the sequential Stage-GateTM. Ostensibly, each of the front-end routines can be mapped onto the stages of the traditional Stage-GateTM model, that is, opportunity recognition versus discovery (Stage 1), idea generation versus scoping (Stage 2), and concept definition versus business-case development (Stage 3). We posit, however, that the front-end routines occur in each of the stages in the Stage-GateTM model, that is, opportunity

recognition takes place – albeit to a different extent – in discovery, scoping, and business-case development. In Stage 1 there is a greater emphasis on opportunity recognition while in Stage 3 there is a greater emphasis on concept definition. We believe that this is an important difference between both models since the holistic model allows for iteration between the three routines in all stages. Iteration is an essential part of the front end. For example, working on concept definition may identify several risks and costs not initially identified, which can lead to several new ideas, which can then in turn lead to several new concepts.

FRONT-END ROUTINES IN EXPLOITATION PROJECTS

Most empirical studies on the front end have examined exploitative projects. Cooper's (2001) research, while not specifically focused on the front end, determined best-practice factors based on studies of large samples of successful and unsuccessful exploitation products. Out of the nine success factors Cooper and colleagues identified for NPD performance, three are applicable to the front end: product superiority, product definition, and up-front activities. Product superiority concerns relative product performance, that is, the benefits, quality, reduced costs, superiority, and problem-solving ability compared to competitive products. "Product definition" reflects the "whats" and "for whoms" of the product concept prior to product development, and the third success factor, "up-front activities," refers to the initial screening, preliminary market assessment, and financial analysis of the project. Similar results were found by Song and Parry (1996) who looked at new-product introductions in Japanese high-technology firms.

There have been six empirical studies that specifically look at the front end. The first four focused on exploitation projects. Bacon *et al.* (1994) indicated that the front end will lead to a well-understood product definition, which, in turn, is linked to overall product-development success. Moenaert *et al.* (1995) investigated the integration of marketing and research and development (R&D) activities and how information exchange between marketing and

R&D affects success. Khurana and Rosenthal (1998) published the first comprehensive study of front-end activities on the basis of case studies of 10 incremental and 2 radical projects. They discovered that successful organizations follow a holistic approach to the front end. Furthermore, Khurana and Rosenthal (1998) classified front-end success factors into foundation and project-specific elements. Foundation elements refer to having a clear product strategy, a well-planned portfolio of new products, and an organizational structure that facilitates product development via ongoing communication and cross-functional sharing of responsibilities. The project-specific elements help clarify the product concept, evaluate it through executive reviews, and develop plans, schedules, and estimates of the project's resource requirements.

Langerak, Hultink, and Robben (2004), in their study of 126 firms in the Netherlands, developed a mediated model of market orientation on new-product performance. The mediators were strategic planning, idea generation, idea screening, and business analysis. Market orientation was measured using a 17-item construct consisting of three subscales for the company's customer orientation (i.e., understanding customer needs), competitor orientation (i.e., understanding the competitors), and interfunctional coordination (i.e., the degree to which the company's functional departments satisfy their customers). The authors found a strong correlation between market orientation and strategic planning, idea generation and idea screening – but not to business analysis. Strategic planning and idea generation were the only mediators correlated with new-product performance. The importance of having a market-oriented focus is congruent with the work of Cooper (2001); but the lack of significant correlation between business analysis and new-product performance is not. Perhaps the explanation for this difference can be attributed to the kind of projects that were surveyed. Langerak, Hultink, and Robben (2004, p. 300) requested the survey respondents to report on "... a new product... new to the firm ..." but where the company was "... familiar to the market." These types of projects are often classified as exploratory since they involve some degree of newness (on the product

level) and hence require learning. Cooper's (2001) study was mostly confined to exploitation projects (i.e., cost reductions, improvements to existing products, and repositioning, etc.).

Verworn, Herstatt, and Nagahira (2008) evaluated the front end of 497 projects from Japanese companies. They developed a structural equation model relating three front end factors, that is, "reduction of market uncertainty," "reduction of technical uncertainty," and "intensity of initial planning" to two NPD success factors at the project level (efficiency and effectiveness). They found a significant correlation between reduction of market uncertainty and effectiveness and reduction of technical uncertainty and both efficiency and effectiveness. Intensity of planning was significantly correlated with reduction of market and technical uncertainty as well as with efficiency. Hence, Verworn, Herstatt, and Nagahira (2008) found that the intensity of planning contributes in indirect ways to NPD success (i.e., effectiveness). The significance of a direct relationship between intensity of planning and effectiveness was not tested.

Bertels, Koen, and Kleinschmidt (2008), in their study of 238 companies, tested mediated models of predevelopment performance. The effect of organizational resources on predevelopment performance was hypothesized to be mediated by front-end routines. Predevelopment performance consisted of a six-item construct, which measured the relative competitive advantage and risk profile of the business units' front-end activities. In contrast to the earlier studies, Bertels, Koen, and Kleinschmidt (2008) developed separate mediated models for exploitation and exploration. For exploitation, they found that both opportunity recognition and idea generation were correlated with predevelopment performance, whereas concept definition was not. These results are in line with previously discussed studies (Langerak, Hultink, and Robben, 2004), which show no significant correlation between business-planning efforts and success. Business planning, based on Cooper's (2001) extensive studies, has long been considered an important contributor to overall success of the front-end activities. However, the last three studies provide empirical support for the alternative

hypothesis of no significant relation. A similar debate is occurring in the entrepreneurship literature. A recent meta-analysis (Brinckmann, Grichnik, and Kapsa, in press) of 47 studies found that the business-planning process as opposed to the actual business plan had a higher correlation with success. However, no large firms were included in the meta-analysis.

FRONT-END ROUTINES IN EXPLORATION PROJECTS

Front-end routines well suited to exploration projects are less well established. The effectiveness of certain routines is dependent on whether the projects reinforce the company's current value network or require a new one. A *value network* is defined as "the context within which the firm identifies and responds to customers' needs, procures inputs and reacts to competitors" (Christensen and Rosenbloom, 1995, p. 234). It includes "its upstream suppliers; its downstream customers, retailers, and distributors; and its partners and ancillary industry players" (Christensen, Anthony, and Roth, 2004, p. 63). It is the organizational reflection of how the firm is networked to compete within a business model and encompasses the network of commitments and relationships that need to be maintained. The work of Christensen and colleagues on disruptive innovation explains why incumbent firms have difficulty developing products for new value networks.

Front-end routines for exploration projects in the existing value network. The discovery of stents is an example of an innovation that was aligned with the value network that existing companies in interventional medicine were already serving. Stents are used in a procedure for noninvasively expanding restricted cardiac arteries called *angioplasty*, which allowed companies to rapidly expand their market by solving one of the major problems associated with this procedure. Before the discovery of stents, angioplasty procedures to open obstructed cardiac arteries often could not prevent the spontaneous closure of the arteries resulting in repeat procedures. This limited the usefulness of the procedure. Stents solved this problem by preventing the artery from closing. Effective front-end routines

to develop stents are essentially the same as those discussed for exploitation projects. The company would first need to recognize that the opportunity for interventional medicine would be significantly enhanced if they could prevent spontaneous closure of the arteries. Several ideas and concepts can then be developed. The only difference from exploitation, however, is that these ideas and concepts require radically new technologies (i.e., stents).

Large firms have adopted a technology Stage-Gate™ (TSG) process (Ajamin and Koen, 2002; Schwartz, Yu, and Modlin, 2004) as modification of the traditional Stage-Gate™ process when dealing with high uncertainty radical technologies. The objective of the TSG process is to build confidence in a technology to a point where the feasibility is demonstrated and a product-development program can be initiated. The TSG lies within the front end since traditional development efforts (i.e., past Gate 3) should not be started when there is significant technical uncertainty. The TSG process holds the team accountable only to the next gate since the outcomes of the technology efforts cannot be predicted a priori. The TSG process embraces the concepts embodied in real options theory (McGrath and MacMillan, 2000) where a limited investment is made at each stage. A go/no go decision is made after each stage, depending on overall risk and value assessment based on the information collected during the previous stage. For the most part, the studies carried out in understanding the front end for exploitation projects can be applied to the routines in existing value networks.

Front-end routines for exploration projects in a new value network. Corning's optical-fiber program, General Electric's development of computerized axial tomography, Motorola's development of cellular phones, and Searle's development of NutraSweet (Lynn, Morone, and Paulson, 1996) created entirely new

markets which required new value networks. Lynn, Morone, and Paulson (1996) found that the development of such products did not follow the traditional serial Stage-Gate™ routines employed for exploitation products, but followed a learning strategy, which they called the *probe and learn process*. These products required an iterative process of development and testing where early versions of the product were developed, tested in the market, tweaked, tested, and adjusted. These market probes allowed for emerging insight into what markets to pursue and what features and benefits provided value to the customer.

O'Connor and DeMartino (2006), on the basis of in-depth study of 12 radical innovation projects, identified 3 radical innovation competencies: discovery, incubation, and acceleration (*see* RADICAL INNOVATION). In the discovery stage, ideas are formulated and screened against development costs, market potential, and overall strategic value to the company. In the next stage, incubation, initial prototypes are created, which are suitable for sales and testing (this is comparable to Lynn, Morone, and Paulson (1996)'s probe and learn process). The third, or acceleration stage, requires the new product to begin to scale up and create an actual business. We have added a fourth stage, institutionalization, which considers the integration of the new opportunity with the existing business units or the development of a new business unit reporting to the traditional hierarchy of the company (Garvin and Levesque, 2005). We have developed Figure 2 to illustrate these four stages. The first three stages, while described in a sequential nature, are not sequential in practice. There is considerable learning from the second stage and third stage back into the discovery or first stage. In essence the second and third stages should also be considered as part of the front end since the learning causes new ideas to be discovered and tried out in the market place. An alternate and, perhaps, more encompassing model for

Figure 2 Front end for new value network exploration projects, which follow a probe and learn process. (adapted from O'Connor *et al.*, 2008).

radical innovation has been proposed by Reid and de Brentani (2004). This model includes the environment, the individual, and the organization. Unfortunately, this model assumes that the different stages are of a sequential nature.

Garvin and Levesque (2005) describe an emerging business opportunity (EBO) unit being used at IBM to develop opportunities that require new value networks which they describe as the "... white spaces between established businesses" (Garvin and Levesque, 2005, p. 9). The EBO unit is separated from mainstream with its initial efforts focused on understanding unmet customer needs in the marketplace. IBM makes extensive use of ethnographic methodologies (Rosenthal and Capper, 2006) whereby the development team observes the customer in his or her habitat to obtain deep insights around how the consumer experiences a product, improvises a solution, or deals with the environmental factors.

In the beginning, the strategy for a new EBO is an iterative process. People at IBM said that "sometimes it would take a year to a year and half to get the strategy we were happy with. It would change three or four times" (Garvin and Levesque, 2005, p. 10). Different from the more structured Stage-GateTM process, review meetings for EBOs, which are held at monthly intervals, are focused on strategic clarity and understanding significant unmet customer needs. Financial proformas are used to understand the key assumptions of the project as opposed to evaluating the project on the basis of established financial hurdle rates. Project initiation and selection in the EBO structure follow the "probe and learn approach" where ultimate project approval is the result of many iterations guided by monthly senior-management dialogues. The EBO system, initiated at IBM in September 2000, has proved to be quite successful. As of spring 2003, the EBO unit had created two new business units that began generating over \$1 billion in annual sales and a number of others with annual sales exceeding \$100 million.

In addition to ethnographic approaches, some companies use a lead-user methodology to find new breakthrough ideas (von Hippel, 2005) (see LEAD USERS). Lead users, or the first inventors of a product, across seven different

industries, were found to be responsible for the development of a minimum of 11% (electronic assembly) to a maximum of 100% (scientific instruments and semiconductor equipment) of breakthrough inventions. Lead users are different from other users because they are at the leading edge of an identified trend in terms of new product and process needs and because they expect to obtain a relatively high net benefit from solutions to their own need. A careful assessment of the lead-user approach at 3M (Lilien *et al.*, 2002) showed that this approach led to seven entirely new major product lines, which created \$146 million (mean) in new-product sales over a five-year period as compared to the traditional approach for generating new-product lines, which created \$62 million (mean) in new-product sales.

CONCLUSIONS

Compared to the work done on the product-development part of the innovation process, research in the front end remains relatively sparse. Nevertheless, organizational resources and front-end routines required for exploitation projects and for exploration projects that fit in firms' established value networks are thought to be understood. In contrast, findings related to the organizational resources and front-end routines required for new value network exploration projects are just beginning to emerge. What is apparent is that these new routines require a more iterative or learning approach. However, most companies have difficulty adopting this new approach since the skills and competencies involved are so different from those used in exploitation projects (March, 1991).

quality function deployment (QFD)

John R. Hauser, Abbie Griffin, Robert L. Klein, Gerald M. Katz, and Steven P. Gaskin

DEFINITION

Quality function deployment (QFD) is a product-development methodology whose objective is to “deploy” the VOICE OF THE CUSTOMER (VOC) throughout the product-development process. It is most often carried out by a CROSS-FUNCTIONAL TEAM that creates and populates a series of one or more matrices, the first and most common of which is referred to as the *House of Quality* (HOQ). When completed, these matrices relate customer wants and needs (the VOC) to an extensive set of product features. A set of metrics is developed to measure how well any given set of product features is meeting customer needs. These metrics are then used to identify and prioritize the product’s design specifications (*see* PRODUCT SPECIFICATIONS).

DESCRIPTION AND COMMENTARY¹

QFD is believed to have been developed in the early 1970s at a Japanese shipbuilding firm. Its objective was to provide a systematic way of dealing with the many complexities and trade-offs inherent in all the design decisions faced by product developers. After considerable study and a number of improvements by several important Japanese academics, it later migrated to the Japanese auto industry and then to the US auto industry by the mid-1980s (Hauser and Clausing, 1988). Today, it is used in almost every type of industry and application imaginable – products and services, consumer (B2C) and commercial (B2B) applications, high tech and low tech industries, and so on.

QFD is best carried out by an active cross-functional team whose job is to complete one or more of a series of matrices that lead to a set of insights about how best to create a winning product or service and how to prioritize their research and development activities going forward. Many QFD practitioners believe that most of the learning takes place during the

process of debate among the cross-functional team members in trying to reach consensus on the various entries into the matrix.

A rigorous view of QFD employs not just one matrix (the original HOQ), but four. These are sequentially related as follows:

- customer needs to performance measures
- performance measures to features or solutions
- features or solutions to parts specifications
- parts specifications to manufacturing processes.

A variation on the second of these matrices is called the *Pugh concept selection*, developed by Prof. Stewart Pugh in the United Kingdom. This variation attempts to evaluate different product concepts against the key performance measures, with the objective of incrementally moving toward an ideal concept.

There are many different styles of conducting QFD, and practically no two practitioners follow exactly the same process. A particularly lively debate has to do with the importance of completing all four matrices, with many practitioners arguing that most of the value is derived from the first matrix alone.

It is well recognized that customers choose products on the basis of how well the products fulfill their perceived needs. New-product development teams must select product features to fulfill those perceived needs.

Figure 1 illustrates a stylized HOQ completed by Puritan-Bennett, a medical-device manufacturing company, when they were redesigning a medical instrument called a *spirometer* (a device that measures lung capacity). The HOQ begins with a formal study of perceived customer needs called the “*Voice of the Customer*.” The VOC identifies customer needs such as “the product is easy for the physician to hold while taking measurements on a patient.” In the Puritan-Bennett example, interviews with physicians, technicians, nurses, and patients identified 25 strategic customer needs. These are listed on the left-hand side of the matrix.

However, all needs are not equally important. The customers would much prefer that some needs be fulfilled even if it means that other

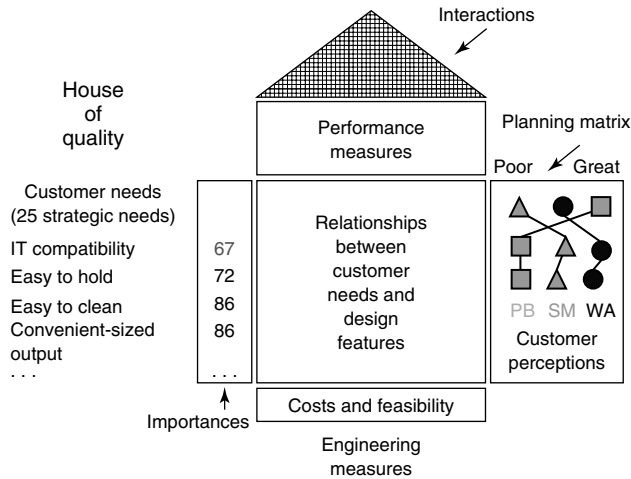

Figure 1 Illustrative house of quality.

needs are not fulfilled as well. The VOC, in addition to defining customer needs, also measures the importance of each need. In Figure 1 these measures of importance are listed to the right of the list of customer needs. In addition, the HOQ lists on the right how each existing product (shown for three manufacturers that we label PB, SM, and WA) fulfills the customer needs. For example, WA does extremely well on the important customer need of affordability, while PB does poorly. The diagram shows that affordability is a high-priority need.

The remainder of the HOQ is reasonably self-explanatory. The product-development team lists performance measures at the top of the house. For spirometers, a performance measure might be the weight, the diameter, or the number of minutes required to clean it.

The team then considers each high-priority customer need, such as "information technology (IT) compatibility," and, in the center of the house, indicates how each performance measure affects the fulfillment of that need. For example, a small diameter may make it easier for someone to hold (positive relationship), but take longer for someone to clean (negative relationship). Some teams indicate the relationships with symbols (●, ○, ◐), others with numbers (± 9 , ± 3 , ± 1), and still others with simply + or -. The HOQ is a guide; any quantification must be tempered with qualitative judgment.

The triangular roof of the HOQ holds interactions between performance measures. For example, it is likely that a larger diameter is positively correlated with a higher weight product, and thus a "somewhat related" relationship would be noted at the intersection box between them in the roof. At the bottom of the HOQ are costs, technical feasibility, benchmarks, and, possibly, metrics (engineering measures) that are performance goals for this project.

Early applications use large numbers (hundreds) of customer needs and design features, and building the HOQ with that many needs becomes an arduous task. QFD has become somewhat controversial in many organizations owing to the time, effort, and (some would argue) tedium that it involves. Fortunately, excellent software and a number of interesting shortcuts are now available to combat these problems. For example, the HOQ has evolved through the use of "Turbo HOQ" to a representation that is more "just in time." When the team considers a customer need, it fills in the design features to which that need is linked.

Though QFD can involve a good deal of effort, there are a number of key benefits to be derived from its use:

- It allows teams to prioritize their development activities in a systematic, analytical way that puts the customer first, as opposed

to through a political free-for-all that relies on which customer, salesman, or officer can shout the loudest and exert the most power.

- It takes advantage of cross-functionality in an orderly, truly participative way, enlisting the support of all major functions within the organization toward a common view.
- It provides an “audit trail” that reminds people, both new and old to the project, as to why certain decisions were made in the past.
- It often results in a prioritization that is highly unexpected and different from the conventional wisdom held by the company and many of the participants before engaging in QFD, thus stretching the team’s thinking as to which activities are most critical toward creating a winning product or service.

Having noted the benefits, let us turn to some examples showing why and how QFD can be helpful in the product-development process.

Much of the effort involved in QFD is devoted to the relationship between customer needs and features during the QFD process. Why is it so hard to relate customer needs to engineering features? Consider a liquid dishwashing detergent (for washing dishes by hand). It is basically a chemical product. Customers buy it to clean their dishes. But what does “clean” mean to customers in the context of dishes and how do customers judge that their dishes are clean? It is unlikely that they use a magnifying glass or a scientific instrument to measure the light reflected from the dishes, although an engineer might use those instruments to test a dishwashing product’s performance. It is also unlikely that the customer will read and understand the chemical ingredients. More likely, the customer will use some subjective means to determine “clean.” This might mean holding dishes up to the light or it might simply mean that there is no noticeable dirt on the dishes – a minimum requirement. Tactile cues, such as running fingers along a dish to detect the presence of grease, may play a role. In addition, the customer might derive peripheral cues, such as the clarity of the water in the sink (after washing dishes) or the amount and type of bubbles that are still around when the dishes are done and ready to be rinsed. The scent of the dishwater or of the dishes might be another cue to cleanliness.

quality function deployment (QFD) 3

But “clean” might not be the only perceived need. The customer might care about the ease of use, the “feel” of the water while washing the dishes, the scent of the liquid, the effect of the dishwashing liquid on skin, the ease of storing the bottle (or package), whether the washing causes the dishes to deteriorate, how much is needed to wash a sink full of dishes, or whether the liquid imparts a perceived taste to the dishes. It is not enough to engineer the best cleaning liquid. The product-development team must engineer the entire customer experience. This includes the liquid itself as well as the packaging and any advertising image.

Consider another example – engineering a telephone-service center to provide great service. The development team may design the physical space, select the telephonic equipment, and design protocols. The development team may also design a personnel policy, training, and a monitoring/reward system. Consider the monitoring/reward system. One major financial service provider determined that customers did not like to wait. They instituted metrics and rewarded the service providers to minimize the number of rings before answering, avoid transferring customers, and answer the customers’ questions as rapidly as possible. Unfortunately, the service representatives soon figured out how to “game” the system: answer the phone quickly, avoid a transfer even if the service provider did not know the answer, and get off the phone as quickly as possible. In fact, the metric was improved by giving incomplete and unhelpful answers.

The financial services firm responded. Service providers were now given incentives to stay on the phone until the customer got an answer. One metric was the number of minutes per hour that the service provider was on the phone. The service providers responded. They were never off the phone. Breaks were taken while the customer was on hold.

Ultimately, the financial services firm talked to the service providers and understood their needs. Service providers were not happy with gaming the system. They wanted to serve customers but felt that the metrics prevented them from doing so. In response, the firm began using more qualitative metrics based on monitoring and on customer satisfaction scores. Service providers

4 quality function deployment (QFD)

started to maximize the customers' perceived needs – the customers wanted their questions answered correctly. Efficiency was a secondary criterion.

Many other examples abound. Fulfilling customer needs is important to the success of a new product, but it is difficult to achieve. It is especially difficult in a complex product such as an automobile or a high-end copier. An automobile may take 1000 person-years to design – millions of decisions need to be made. Even an office copier may require close to 10 000 critical engineering decisions. Effective product developers want every one of those decisions to be focused on the customer.

Since customer needs drive the entire QFD process, it is critical that the list of customer needs be complete; otherwise, important factors in product design may be omitted. The *Voice of the Customer* is a term used in business to describe the process of capturing a customer's requirements (see VOICE OF THE CUSTOMER). The VOC is a product-development technique that produces a detailed set of customer wants and needs which are organized into a hierarchical structure, and then prioritized in terms of relative importance and satisfaction with current alternatives. It involves both qualitative and quantitative market research among current and potential customers. Sometimes, practitioners are tempted to gather the VOC in a very cursory way for reasons of time, budget, or lack of interest

in what their customers have to say. This is rarely a good strategy – the quality of the output depends upon the quality of the input. Gathering a good VOC takes time, and requires knowledge of sample design, recruiting of research respondents, good interviewing techniques, the ability to translate interview output into a useful set of needs, and so on. For practitioners new to the VOC process, it is good practice to obtain some training from experienced VOC practitioners before attempting to conduct this research, or to outsource this task to them (for more information see VOICE OF THE CUSTOMER).

Another major benefit of QFD is that it improves communication among members of the product-development team. Here is an example. In the early days of QFD, MIT Sloan researchers studied its implementation at Ford Motor Company (Griffin and Hauser, 1992). Two teams were chosen. Each was working on a similar, but different, component of a new automobile and each team was otherwise similar in terms of skills and team members. Both teams reported to the same managers. One team used the QFD/HOQ; the other team used Ford's standard phase-review process. Over the course of the product-development cycle, the MIT Sloan researchers measured the amount and type of communication among team members. The results are given in Figure 2.

Overall, there was significantly more communication among members of the QFD team.

Figure 2 Communication at Ford.

Deeper analysis revealed that QFD focused its communications within the team – both within functions and between functions in these interfunctional teams. The only type of communication reduced by the HOQ was that between the QFD team and management. Even deeper analysis showed that the phase-review team engaged in significantly more “up-over-down” communication. For example, an engineer at Ford might communicate a design change to his/her manager who would communicate that design change to a manager at a supplier who would, in turn, communicate the design change to an engineer at the supplier. In the HOQ team, the Ford engineer communicated directly with the engineer at the supplier.

Figure 2 is just one example of the success of the various means to enhance communication among product-development team members concerning the relationship between perceived customer needs and engineering design features. Figure 2 is based on QFD, but there are many other ways to effect communication during the product-development process. For example, Wind *et al.* (1989) provide an excellent example of how conjoint analysis was used to design “Courtyard by Marriott.” They show how, in addition to the usual quantification of trade-offs, conjoint analysis was used to link the features of the hotel to perceived customer needs. Green, Krieger and Wind (2004) provide another example where conjoint analysis was used to design the EZPass (FastLane) electronic toll-payment system (Green, Krieger, and Wind, 2004).

The important lesson here is that such communication must occur if successful products are to be designed. It is far more efficient and effective to incorporate the VOC into the new-product development process proactively, and early on, through a systematic process such as QFD, than it is to redesign the product after an unsuccessful launch.

creativity

Jacob Goldenberg and David Mazursky

INTRODUCTION

Karl Popper expressed traditional thinking about creativity when he stated, “Creativity is a divine spark that may not be dismantled and examined by use of scientific tools.” It is not surprising, therefore, that until the 1970s, no thorough scientific investigation of creativity has been conducted. For many years, the study of creative thinking and methods that render this process more effective remained the domain of practitioners such as engineers or advertisers, who sought tools to enhance their ordinary problem-solving tasks. In the last 30 years, however, many creativity-enhancement methods have been proposed and many have enjoyed immense popularity. Common to most of these methods is the belief that to ignite the creative spark, all we have to do is break away from existing conceptual frameworks, suspend all judgment and criticism, and search diligently for the nonconventional. A small minority propounds a more systematic approach to creativity enhancement.

In the academic world, the pioneers who broke the “taboo” on research in this field were cognitive psychologists, who were later joined by investigators in other disciplines such as neuropsychology, artificial intelligence, engineering, education, and, more recently, marketing and management science researchers. In this way, it was long after the adoption of various creativity-enhancement methods by practitioners that academic research began to investigate the common beliefs and underlying assumptions of these methods, and construct a scientific knowledge base in this area.

Here, we focus on creativity in new-product ideation with an attempt to conceptualize what is known today. An introduction to definitions of creativity is followed by an overview of the underlying assumptions about effectively developing creative products, and contemporary directions of research on creativity. We explain two very different approaches to enhance creativity in greater detail, including the numerous variations that have been suggested

and are in use. The discussion section concludes with some thoughts on future progress.

DEFINITION

Creativity is considered the ultimate of human qualities and one of the key measures of intelligence that is manifest in many fields. Creativity is also an enigmatic phenomenon. Like intelligence, it represents a highly complex and diffuse construct revealed by the wealth of available definitions for creativity (Sternberg, 1985, 1988). Despite various differences in these definitions, *creativity* is often defined as useful novelty – “not novelty for its own sake, but novelty that can be applied and adds value” (Oldham and Cummings, 1996), and most definitions share these two elements: (i) novelty or originality and (ii) usefulness, value, or benefit (Boden, 1995; Mumford and Gustafson, 1988). Mayer (1999, p. 449), for example, notes that most authors who contributed to the Handbook of Creativity endorse the idea that creativity involves the creation of an original and useful concept. Table 1 summarizes literature (mainly outside new products) that holds that the two main components of creativity are originality and usefulness: most works, however, do not offer measures of the various dimensions.

This accepted conceptualization of creativity has also been confirmed by findings of a recent study (Goldenberg *et al.*, 2009), which used *similarity structure analysis (SSA)* (Guttman, 1968; Shye and Elizur, 1994), a type of multidimensional scaling (MDS) technique that provides spatial representations of the relations among variables: the more highly correlated a pair of items, the closer these two items are located in the space. The SSA analysis performed on 19 new products, revealed a three-dimensional structure (see Figure 1) that confirms the perception that creativity is a combination of originality and usefulness. It is therefore not surprising that researchers in marketing refer to and use these dimensions when studying creativity.

Creative ideas are also believed to contribute to the thinking atmosphere and the enhancement of productivity, even when they do not produce immediate profit (Weisberg, 1992). “Generating interesting designs is desirable not only because

Table 1 Dimensions of creativity.

| <i>Originality</i> | <i>Usefulness</i> | <i>Source</i> |
|------------------------|--|--|
| Novelty | Appropriateness | Amabile (1983) and Jackson and Messick (1965) |
| Novelty | Usefulness | Gilford (1967), Ray and Myers (1986), Mumford and Gustafson (1988), Sternberg (1988), Osche (1990), Lubart (1994), Sternberg and Lubart (1995), Oldham and Cummings (1996), Gruber and Wallace (1999), Lumsden (1999), Martindale (1999) and Unsworth (2001) |
| Novelty | Socially valued | Taylor, Smith, and Ghiselin (1963) |
| Novelty | Tenability | Stein (1953) |
| Originality | Value | Sobel and Rothenberg (1980) and Young (1985) |
| Originality | Meaningfulness | Haberland and Dacin (1992), Thorson and Zhao (1997) and Wells (1989) |
| Originality | Worth or usefulness | Rothenberg and Hausman (1976) |
| Originality | Appropriateness | Runco and Charles (1993), Amabile (1997) and Kasof (1995) |
| Originality | Effectiveness | Field (1968) |
| Uniqueness | Meaningfulness | Sethi, Park, and Smith (2001, p. 74) |
| Unusualness | Appropriateness | Jackson and Messick (1965) |
| Surprise | Effectiveness | Bruner (1992, p. 3) |
| Divergence | Relevance | Smith and Yang (2004) |
| Divergence, difference | Fruitfulness, helpfulness, constructiveness – in short, productiveness | Tellis (1998, p. 83) |

these designs will often be better than previous solutions, but also because they lead to a new way of thinking about the problem” (Ulrich, 1988).

In view of the potential gains involved, we should not be surprised at the vast resources invested in the search for guidance on how to cultivate and promote creative ideation. Efforts to study and develop methods for enhancing creativity broadly reflect one of two different answers to the question “Where is creativity located?” Accordingly, approaches and methods are characterized by either a focus on individuals, or a focus on ideas.

SEEKING CREATIVITY IN THE INDIVIDUAL

In the first approach to gaining a greater understanding of how creativity works and how it can be fostered in new-product development, the individual is viewed as holding one of two major roles: either as the creative personality who conceives the original idea, or as the repository of information on the basis of which new creative

ideas can be developed by others. Investigators who follow the first view have concentrated on producing a profile of the creative individual, for example, by conducting physical examinations as well as personality tests on people who were considered to be creative.

On the basis of their studies of the creative personality in the early 1970s, cognitive psychologists constructed a quantitative yardstick for measuring creativity: a creative person was someone with a large flow of ideas in a given unit of time (Marschak, Glennan, and Summers, 1967). It was thought that from the greater number of different ideas thus produced, the creative person can cull higher quality ideas that might be absent from a smaller set of ideas.

More recent studies, however, have cast doubt on this criterion by showing that a large output of ideas does not necessarily lead to creative ideas. Furthermore, the very occupation with ordinary ideas seems to hamper creativity and innovative thought. In short, no correspondence

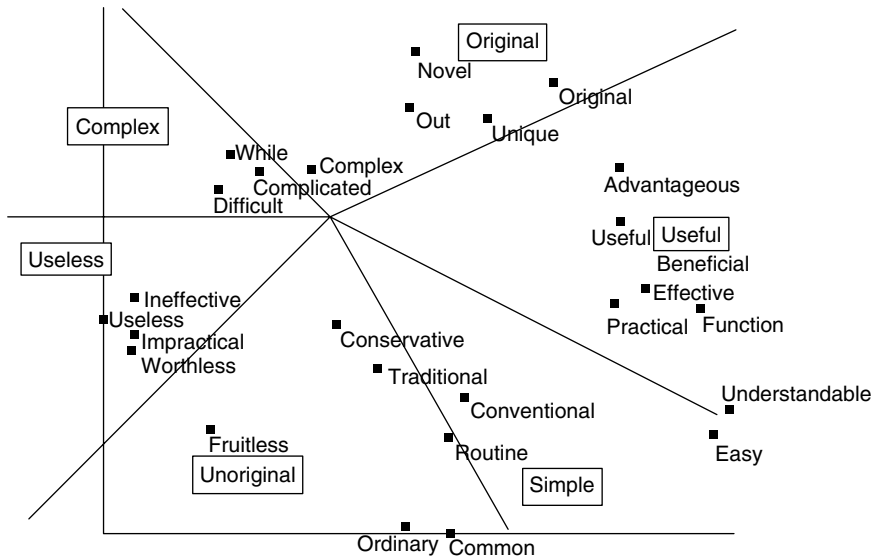

Figure 1 Dimensions of creativity.

between quantity and quality of ideas appears to exist (Connolly, Routhieaux, and Schneider, 1993; Paulus *et al.*, 1993; Stroebe, Diehl, and Abakoumkin, 1991).

The second view of the individual's role in the creative ideation process is epitomized by the market research approach, which sees the individual as the major input and source of information for the creative ideation process. Marketing theory offers many tools for market analysis and data mining designed to promote original ideas by tapping into consumers' views in the search for unfulfilled needs in the market that can be translated into creative new-product offerings. Some individuals may be more instructive than others in this context. According to Von Hippel (Urban and von Hippel, 1988; Von Hippel, 1989), valuable information may be gathered by being attentive to "LEAD USERS". Von Hippel indicates that these users serve as an "ideational elite" and possess unique information about future needs. By creating solutions to their own problems, they are frequently able to provide information for the development of new products, and to predict their success.

The ability of market research, or "the consumer's voice" (*see VOICE OF THE-CUSTOMER*), to elicit truly *original* concepts

has come increasingly into question, and specific arguments have recently criticized the value of marketing research as a source of new-product ideas (Durgee, O'Connor, and Veryzer, 1996). In fact, a close look at historical data reveals that many new and surprising products were never developed from market research; Even products that have entered the "Hall of Fame" of innovation and creativity were envisioned by a diverse group of individuals, some of whom had no knowledge at all about the market for the products they developed, and some never even imagined that the market would be interested in their inventions.

These critics explain that consumers are simply not a beneficial source of information of the kind that triggers creative ideation: many desires and needs lie below the surface of consciousness, and current product users are not able to clearly articulate for nonexistent products. Griffin and Hauser (1993) also expressed doubts about consumers' ability to predict exactly which products the firm should develop, the details and features of the future blockbuster products. More generally, researchers doubt whether consumers provide reliable information beyond their personal experience or knowledge (*cf.*, Griffin and Page, 1996), Von Hippel (1984)

summarized the problem succinctly: “Clearly, the average user of today’s product has no experience with tomorrow’s products . . . the average user is in a poor position to provide accurate data about future products to market researchers.”

The use of market research data as a source for creative product ideas – ideas that are both useful and novel – is further undermined by the low probability of an exclusive discovery of an emergent need and the subsequent introduction of an innovation to the market (for more details see Goldenberg, Mazursky, and Solomon, 1999a). In view of the aggregate dynamics of an emerging desire or need, and its propagation in the market, Goldenberg and Efroni (2001) conclude that by eliciting information from consumers, a firm operating in a market with few competitors may discover an emerging need when the gradient of the awareness propagation process is large, that is, this discovery is less likely to lead to a truly new innovative product idea because an increasing number of competitors are simultaneously in the process of its discovery.

While market research may be imperative for understanding how products should be modified to meet market needs, it can determine the best design of a product given market preferences, predict the product’s success, and ascertain the most appropriate time to launch the new product (see also PRODUCT TESTING). However, as a representation of market reality at a specific time, marketing data offers a poor indication of future market needs, and thus offers a poor foundation for creative product ideation.

FOCUSING ON THE IDEATION PROCESS

Look outside the box?. A common lore is that creativity exists “outside the box.” The source of this famous notion seems to be the nine-dot puzzle, which may be the only problem that actually has a box, and whose solution exists beyond itself. How reliable is this belief?

Creativity is a young scientific discipline whose roots can be traced to the early 1970s, when a psychologist named Guilford was one the first researchers to conduct a scientific study of creativity. One of Guilford’s most famous studies was the nine-dot puzzle, presented with its solution (Figure 2). The problem is to

Figure 2 The nine-dot puzzle and its four-line solution.

connect all nine dots using four lines, without lifting your pencil from the page. Today, more people know about this puzzle, but in the 1970s very few were aware of its existence despite its long history.

The correct solution to this problem requires the solver to draw lines that extend *beyond* the area confined by the dots, yet would-be solvers usually confirm that their first attempts at a solution typically involve sketching lines *inside* the imaginary square. All the participants in Guilford’s original study were similarly ensnared by the imaginary square and were unable to “see” the white space beyond the square’s boundaries. Only 20% managed to break out of the illusory confinement and extend their lines into the white space surrounding the dots. The beautiful simplicity of the solution and the fact that 80% of the participants were mesmerized by the square while only 20% of all participants solved this puzzle correctly, led Guilford and the readers of his publications to leapfrog to the sweeping conclusion that creativity requires one to go “outside the box.” Overnight it seemed that creativity gurus were preaching and teaching managers how to enhance their creative potential by thinking “outside the box.”

The nine-dot puzzle became an icon for creativity and the phrase “thinking outside the box” rapidly spread in marketing, management, psychology, personal improvement. There seemed to be no end to the insights that could be offered under the banner of “thinking outside the box.” Speakers, trainers, training-program

developers, organizational consultants, university professors – all had much to say about the vast benefits of outside-the-box thinking. The concept enjoyed such strong popularity and intuitive appeal that few bothered to check the facts.

In the 1970s, around the same time as Guilford conducted his experiments, another much less known study was conducted (Weisberg, 1992). This experiment used the same puzzle, but a different procedure. Participants were divided into two groups: the first group was given the same instructions as the participants in Guilford's experiment. The second group was informed that the solution requires the lines to be drawn outside the imaginary square bounded by the dot array. Surprisingly enough, only 25% of the group that received the clue solved the puzzle correctly, which is not a statistically significant difference.

Even though the solution requires participants to literally think “outside the box,” participants' performance was not improved even by specific instructions to literally look for the solution *outside the box*. In other words, direct explicit instructions to think outside the box made no impact in improving solution rates.

Inside the box? The nine-dot puzzle study illustrates the underlying flaws of this concept, even though it is frequently used (in abridged form) by many creativity lecturers. The remarkable case of the “Fosbury Flop” (Goldenberg *et al.*, 2010) has featured so frequently at creativity conferences that it has become almost as iconic a symbol of thinking outside the box as the nine-dot puzzle.

The year 1968 is seared in world memory as a phenomenal year in athletics. In high-altitude oxygen-poor Mexico City, Bob Beamon's 8.90-m jump was hailed as the greatest athletic achievement of all time. Beamon's achievement exceeded the previous world record by 55 cm, and remained unbroken for 23 years. Yet in a different corner of the stadium, an unknown athlete was responsible for one of the most dramatic and sensational revolutions that occurred in the history of sports. Introducing a radical innovative technique, Dick Fosbury won the gold medal in the high-jump event with a back-first flip that he himself had invented. This technique was contrary to the conventional

high-jump technique known as the *straddle*, or the *western roll*. With a technique that had never been seen before, Fosbury revolutionized the entire sport. In less than 10 years, virtually all high jumpers had adopted his technique, and the previous high-jump technique became obsolete. This newly embraced method was named the *Fosbury Flop* after its charming and unassuming inventor.

Interestingly, the case of the Fosbury Flop often is used in conventions and features in conference speakers' materials to support the idea that revolutions originate from out-of-the-box thinking. After all, the Fosbury Flop prompted a genuine revolution in the field of high jump, using a technique that was almost the polar opposite to the dominant technique at the time. All athletes used the straddle, in which the jumper approaches the bar with his face toward the bar, and jumps and rolls over the bar with his stomach toward the bar, but Fosbury approached the bar with his side, turning his back to the bar when rolling over it. That he literally used the “opposite” technique was taken as clear evidence that Fosbury was thinking “outside the box.”

The true account, however, illustrates that Dick Fosbury's revolution had nothing to do with thinking outside the box. There is no argument that Dick Fosbury's idea was creative – it was unique and it effectively solved the problem of improving jumpers' performance. But according to Dick Fosbury's own account of the Fosbury Flop development, there were no leaps in the thought process, it was the result of ordinary thinking: his new idea involved no outside the box thinking.

Fosbury's Flop technique in the high jump began as a result of his first having learned an antiquated, energy-wasting technique called the “*scissors*” at the age of 10. In the fifth grade, at the age of 11, Fosbury's physical education teacher and coach taught all the children trying out for track to jump using the classic style, the *straddle*. Fosbury, however, continued to use the scissors jump until he reached high school, mainly because he was not able to master the straddle enough to improve his performance.

In high school, the scissors were no longer accepted and, in switching to the straddle, Fosbury effectively had to learn how to jump

all over again. His competition results were far behind the other jumpers. Extremely frustrated, Fosbury asked his coach whether he could revert to the old scissors style to improve his results, and maybe boost his confidence a bit. Although he was not enthusiastic, the coach was sympathetic to the young athlete's frustrations and agreed to let him try it. So in a fateful career decision, instead of working to improve his straddle skills, Fosbury reverted to the technique he felt comfortable with, even if it was much older and less "efficient."

Fosbury decided to try his old style on his next competition. Feeling awkward yet determined, Fosbury cleared his previous best jump at 5' 4", but when he faced a new height, he understood that something in the technique had to be changed. With the scissors style, the jumper typically hits the bar off with his/her behind, and sometimes with the movement of the legs. To compensate, Fosbury began to try to lift his hips up higher, which also dropped his shoulders simultaneously. He continued to raise his hips until he eventually cleared 6" and set a new personal record, and even placed fourth to score points for his team.

No one noticed what Fosbury was doing, because he was tweaking the old technique into something new, one tiny step at a time. Each attempt was only marginally different from the previous one. When Fosbury unexpectedly began to beat the other competitors, his rivals' coaches noticed that the athlete was using "something different." When they checked the rule book, they could find no evidence for anything illegal in his strange technique. Fosbury was simply applying incremental improvements. There was no radical change or leap into uncharted territory – Fosbury methodically made incremental changes, all keeping within the scissors concept, until finally he cleared the bar with his back to the bar, arching his hips over, then unarching to kick his heels over and land on his back in the pit. At the 1968 Olympics Fosbury won the gold with his Flop.

While many creativity speakers tell this story to show that Fosbury was thinking "outside of the *straddle* box," when the facts are revealed, it can be seen that this is not the case: Fosbury was, in fact, thinking "inside the *Scissors*-jump box."

A process like No other? Closely related to the diametric approaches of out-of-the-box and inside-the-box thinking, is the division among scholars and practitioners concerning the nature of the creative process itself. Many scholars state that the creative process is a unique occurrence, one that is qualitatively different from ordinary, day-to-day conventional thinking (Guilford, 1950; Koestler, 1964; Mackinnon, 1970; Wallas, 1926).

According to this line of thought, creativity is conceptualized as involving a leap that cannot be adequately formulated, analyzed or reconstructed, a task that requires "complete freedom of symbolic expression" that "fosters the openness, the playful and spontaneous juggling of percepts, concepts, and meanings" (Rogers, 1959) it approaches "the unknown, the mysterious, the puzzling" (Maslow, 1959); it is "often obscure, unknown, unperceived even by the person himself" (Anderson, 1959). This sense of a leap is manifested by numerous descriptions and personal testimonies of creativity as emerging from "thin air," or even from an apparently complete "void." Sinnott argues that "it is common for a new idea to arise almost spontaneously in the mind, often seemingly out of nothing and at a time when a person may be thinking of something quite different" (Sinnott and Anderson, 1959). Helmholtz stated, "[Creative ideas] often enough crept quietly into my thinking . . . they were simply there . . . But in other cases they arrived suddenly, without any effort on my part, like an inspiration . . . Often they were there in the morning when I awoke" (Woodworth, 1938).

Poincaré (1952) describes his work on a mathematical problem in the same vein and in a casual manner: "One day, as I was crossing the street, the solution of the difficulty which had brought me to a standstill came to me all at once." Mozart likewise accounts: "When I am, as it were, completely myself, entirely alone, and of good cheer – say, traveling in a carriage, or walking after a good meal, or during the night when I cannot sleep; it is on such occasions that my ideas flow best and most abundantly" (Mozart, 1952, p. 34).

Guilford has shown that most of the aptitude factors identifiable as belonging in the category of creativity may be classified as a group

of divergent-thinking abilities. These abilities (evaluated by such tests as the “unusual uses”), in contrast to regular convergent-thinking abilities, emphasize searching activities with freedom to go in different directions, if not a necessity to do so to achieve excellent performance (Guilford, 1959, p. 161). The creative process is inherently fuzzy: fuzziness works where contradictions begin and opposites fuse in a paradoxical ambiguity (Kosko, 1992).

Nonetheless, creativity researchers remain divided over the extent to which the creative process itself has a distinctive nature (Maimon and Horowitz, 1999), and whether creativity is an extraordinary event of thinking or an ordinary problem-solving process. Among others, scholars such as Perkins (1981, 1988) and Weisberg (1986) suggested that creativity does not necessarily require a qualitative leap or a creative spark: it is the outcome of ordinary or everyday thinking, from which it is only quantitatively different and does not necessarily require a qualitative leap or a creative spark. Weisberg (1986, p. 69) summarizes this approach as follows: “Creative thinking is not an extraordinary form of thinking. Creative thinking becomes extraordinary because of what the thinker produces, not because of the *way* in which the thinker produces it.”

METHODS TO ENHANCE CREATIVITY: A REVIEW

Creativity-enhancement methods are numerous and diversified. The methods that have been developed, refined, and used by individuals and firms to enhance creativity reflect the underlying assumptions concerning the uniqueness or mundane nature of the creative spark, and the need to search for creative ideas either inside or outside the box.

Smith (1998) provides an analysis of 172 idea-generation techniques used by organizations and creative consultants, which belong to two broad categories of methods: unstructured methods designed to foster the unique, genius-like spark that comes from out-of-the-box thinking, and structured methods designed to impose order on the search for creative ideas (see IDEA MANAGEMENT). In the first and larger group, reflecting the

popularity of the out-of-the-box concept, randomness imposed on the thought process aiming at increasing the fluency and number of ideas; in the second group, the focus is on the quality and originality of ideas without considering their amount. The following review does not encompass all existing methods, but is intended to provide some flavor of contemporary creativity-enhancement methods.

Methods advocating unbounded randomness. The first broad group of techniques aims to identify a singular, unified thought process that leads individuals to generate successful creative ideas in different people. Its advocates collected written, first-person testimonies about the thought processes of creative people, and then attempts to define the general characteristics of the thought process that produces creative ideas. The results turned up countless inconsistencies between thought processes. Every creative person reported different experiences during his or her thinking, and no tangible, defining process that characterized creative thought was apparent. The researchers concluded that free thought and lack of coercion were the foundations of creative thinking – that breaking boundaries and laws, and using free association and intuitive tools, were the portals to creative thought.

Brainstorming. Most methods for the enhancement of idea generation devised over recent decades have been based on the belief that to find an original idea all we have to do is break away from existing (sound) mind frames and search for the surprising and the irregular, reaching the aspired goal of “generating a large number of ideas” (see also BRAINSTORMING). The implicit assumption behind such methods is that the greater the number of ideas, the greater the probability of achieving a set of quality ideas after filtering. Ideation is therefore measured often in quantitative rather than qualitative terms, and is directed in a random manner. Alex Osborn, founder of Batten, Barton, Durstine & Osborn (BBDO) was one of the first to suggest a creativity-enhancement technique – brainstorming. Brainstorming is based on a group of 6–10 people who focus on a problem. The cardinal rule is that judgment is deferred

and criticism prohibited: No line of inquiry is ruled out. The wilder the ideas that survive the better, for they might stimulate a new association that triggers more novel and useful ideas. Participants are encouraged to build upon ideas as they emerge, combine, and improve them. The atmosphere is positive; the objective of the brainstorming session is quantity, with the assumption that it leads to quality.

Following a first stage of divergence (conceptual brainstorming) – or what is termed by de Bono as “*messing around with ideas*,” the method proceeds with an attempt at convergence (screening). During the second stage, the ideas (tens or sometimes hundreds) are filtered to produce a smaller set, which is subsequently examined and tested for economic feasibility and value, to produce a final set of novel, useful ideas.

Synectics, which means “bringing forth together” or “bringing different things into unified connection” was developed as a creative problem-solving method by Gordon. Synectics applies to the integration of diverse individuals into a purposeful group. This is an operational theory for the conscious use of the preconscious mechanisms present in human creative activity, and aims at increasing the probability of success in problem-stating, problem-solving situations (Gordon, 1961).

Lateral thinking. Lateral thinking is another widely used method popularized by De Bono (1971). The philosophy behind this approach may be conveyed by the analogy of digging a hole. While structural thinking is analogous to digging down in depth, lateral thinking is analogous to the search for a new spot to start digging. De Bono offers several provocative paths to force the thinker to consider different options for solution. Some of his techniques include inverting the situation, altering the situation to make it provocative, and considering interesting directions just because they are interesting (even where no benefit is seen).

Contrary to brainstorming, here the group does not take primacy; decision about the thinking path to be followed is more important. De Bono emphasizes that every creative idea is logical *a posteriori*, even if it looks illusive *a priori*. Many large organizations have reported

successful cases of the use of lateral thinking, mostly for managerial problems.

Mind mapping. This method calls for a free association and flow of thoughts. An individual is instructed to draw a circle at the center of the paper and write in it a short description of the problem. He or she must then draw new circles around the page representing associations (*not* solutions) to the problem, which are linked to the first circle. Each new circle is now the origin for a new bundle of associations, which are noted again in new circles. When the paper is covered with circles (all linked to each other), the problem solver may look at the map and examine one small cluster of circles to try to find a solution. There are no reports of tests conducted to estimate the efficiency of this method.

Random stimulation. Sometimes presented as a complementary method to mind mapping, random stimulation posits that, if forced into the context of a problem, a remote analogy can sometimes stimulate a chain reaction of new thoughts and liberate a fixation. The method advocates choosing a random word (e.g., nail) and focusing thoughts on how that word could be part of a solution to the problem (e.g., devise a new schedule of production). The method is used mainly in writing and the arts. There are no reports of tests conducted to estimate the efficiency of this method.

Similar methods include *divergent thinking* (Guilford, 1970), in which thoughts flow in all directions from one starting point, even if the path seems illogical; *associative thinking* (Young, 1975), in which one puts together unrelated ideas; and *soft thinking* (Von Oech, 1989), which includes metaphorical, paradoxical, ambiguous, and fantasy thinking (giving the following direction, among others: “be foolish and silly”).

All random-based methods are based on the requirement that judgment be suspended and divergent ideas emerge by associative thinking in an unconstrained space (Grossman, Rodgers, and Moore, 1988; Parnes, 1992). Therefore, the resultant idea-generation process is mostly random, or at least blind and haphazard (Campbell and Paller, 1989; Simonton, 1994).

How effective and efficient are randomness-based methods? Methods based on *unbo-*

unded randomness are still often used in general management (Kiely, 1993; Rickards, 1998) as well as in the advertising industry (O'Guinn, Allen, and Semenik, 2000). Notwithstanding their popularity, they have been questioned in numerous studies (Bouchard, 1969; Connolly, Routhieaux, and Schneider, 1993; Diehl and Stroebe, 1987; Weisberg, 1992) Paulus *et al.* (1993), mainly because proponents of randomness-based methods have failed to provide research evidence of their effectiveness on the basis of a systematic assessment. In particular, they have failed to offer a method for controlling and discarding failed trials, thus dooming all trials and responses to qualitative commensurateness (Blachowicz, 1998, p. 21). One study (SOURCE) testing the performance of a group of problem solvers instructed to randomly "break the rules, get out of the square and shift paradigms," showed no significant differences between the ideas generated by this group and those generated by problem solvers given no instructions. Moreover, the study showed that while such methods may increase the apparent *novelty* of ideation, they decrease the *appropriateness*, *usefulness*, or *effectiveness* of the ideas produced.

As to the synergetic effect commonly identified with such unbounded randomness methods, which presupposes that a group of people thinking together is superior to a "nominal group" in which individuals think alone. It has been repeatedly and conclusively shown by investigators that the most prevalent method of *brainstorming* does not generate more ideas or greater creativity than do nominal groups (Diehl and Stoebe, 1987, 1991). At least one study asserted that this plays only a minor role in creativity ideation. In a controlled experiment, ideas suggested by individuals working alone were even evaluated as superior to those raised in brainstorming sessions (Weisberg, 1992). All in all, groups were shown to be suppressive of individual productivity, and the quality and originality of ideas generated by them to be inferior (Paulus, Ortega, and Brown, 1999; Sutton and Hargadon, 1996).

In the late 1980s, the theoretical foundation of the randomness methods also came under attack. Studies showed that an unrestricted scope does not necessarily lead to a treasure chest of creative

ideas. In fact, restricted processes of thinking are more reliable for creativity (Bouchard, 1969; Connolly, Routhieaux, and Schneider, 1993; Diehl and Stroebe, 1987, 1991; Weisberg, 1992) (see below). In fact, it was further observed that people frequently asked to come up with new ideas sometimes try to find their own regulated means of becoming more productive at ideation tasks. They may, for instance, identify patterns common across different contexts and apply them on an ad hoc basis within a certain category. Such patterns will be less transient than the random extrication of thought (Boden, 1992; Dasgupta, 1994; Weisberg, 1992).

Methods advocating structure and regularity.

Randomness-based methods of ideation enhancement are generally grounded in the belief that accidents and chance events enhance innovation. The belief that chance and irregular thinking enhance creativity is supported by many examples of new products created as a result of accidents or chance events. However, if we subscribe to this belief, we are ignoring the millions of unrecorded events in which accidents and chance events (or dreams) did not yield new products.

Underlying the methods advocating structure and regularity is a perception of creativity as an outcome of ordinary thinking that is only quantitatively different from everyday thinking, and does not necessarily require a qualitative leap (Perkins, 1981, 1988; Weisberg, 1992). Thus, according to Weisberg (1986), what distinguishes creative thinking from everyday thinking is its outcome rather than its manner of production. In support of this notion, Finke *et al.*, found that constraining a problem by allowing fewer resources or components to be used increases the creativity of problem solvers (Smith, Ward, and Finke, 1992).

Compared to methods advocating randomness, methods advocating regularity – briefly reviewed below – manage cognitive processes rather than ideation sessions, are analytical and focused rather than random or blind, and are specific rather than general in applicability. Contrary to the "freedom" approach, the "structure" approach views creativity as a reproducible, learnable, and, in some cases, even potentially systematic thought process (Maimon

and Horowitz, 1999; Perkins, 1981, 1988; Simon, 1979, 1981). The thinking process is linear rather than random, and thus each step in the ideation process stems from the previous one.

TRIZ. In the 1940s, a chemical engineer named Genrich Altshuler postulated that underlying successful creative ideas and products are identifiable, repeated patterns or formulas. The existence of such patterns would obviate the need for searching the souls of inventors or tapping into the subjective thought process behind creative ideas (Altshuler, 1985, 1986). Altshuler's goal was to devise a systematic method to guide "ordinary" engineers toward creative solutions. By applying the principle of reverse engineering to the development process of more than 200 000 patents and technological inventions, he identified more than 40 patterns of invention, which he labeled *standards*. Standards were nonintuitive patterns that could be described, predicted, and controlled, independently of external influences: they consisted of system dynamics that could be determined solely by the intrinsic features of the products – a revolutionary idea in the field of creativity analysis.

Generations of Altshuler's students developed the method, and today it is widely used in many places. The focus of the method is still more technological although there are quite a few reported successes in many other fields. TRIZ methods and activity are reported in many web pages, although no studies on their application to marketing have been conducted.

Morphological analysis. The concept of *regularity* is embedded in a number of current ideation methods; for example, in marketing consider *morphological analysis*. This cluster of methods breaks down a system, outcome, or process into essential subconcepts, each representing one dimension in a multidimensional matrix. Ideas are created by searching the matrix for new, previously nonexistent combinations of attributes (Tauber, 1972). The major shortcoming of this cluster of methods is its lack of specific guidelines for combining the attributes, and its lack of a prescribed reduction mechanism facilitating the process of selecting the best ideas.

Creativity templates. Altshuler's principle has been applied to marketing, where recent creativity research has shown certain fundamental patterns or formulas underlying creative designs (Goldenberg, Mazursky, and Solomon, 1999a; Scott, 1994). In the context of innovation, Goldenberg, Mazursky, and Solomon (1999b) identified certain reoccurring regularities and found that these regularities represent the processes underlying new-product and innovation emergence. These regularities, termed *creativity templates*, were found to be identifiable, objectively verifiable, and generally observable. By virtue of their well-defined nature, templates may be described as step-by-step procedures that individuals can execute.

This approach is conceptually consistent with Altshuler's attempt to uncover the underlying patterns in the creative solutions of technological problems (Goldenberg and Mazursky, 2002). The main difference between Altshuler's approach and the creativity-template approach is the number and parsimony of patterns or templates proposed. Altshuler developed many. Researchers have found that most of the successful new product innovation development processes are covered by merely five distinct templates.

The creativity-template approach is a procedural ideation framework integrating two principles. First, there are several identified universal templates that underlie product evolution. These templates can serve to predict new candidate products by providing the context for ideation. Second, creativity is enhanced when thinking is channeled along predefined inventive routes. This principle is termed the *restricted scope principle*.

It was found (Goldenberg, Lehmann, and Mazursky, 2001; Goldenberg and Mazursky, 2002; Goldenberg, Mazursky, and Solomon, 1999a) that the application of templates may facilitate productive and focused ideation. Individuals who received training in creativity templates proposed more creative ideas than individuals who received training in total freedom methods, according to ratings by purpose-blind judges. Similar findings were obtained when the templates method was applied to creativity in advertising (Goldenberg, Mazursky, and Solomon, 1999b).

In this context of “constrained creativity,” design structures *can* play the role of *attractors*: paths that the selforganized mind tends to follow, assisting the individual to process and organize information by using favorable processing routes proven in the past to lead to productive ideas (Kelso, 1997). The small number of paved routes (i.e., basic mental operations or mechanisms) avoids spending “a lot of time going down blind alleys” typical to brainstorming, and offers the much demanded “escape from freedom,” which reduces anxiety (Fromm, 1941), thus maintaining – in Einstein’s words – the “joy in creative expression and knowledge,” and sustaining the “courage to create” (May, 1975).

Every year, hundreds of millions of dollars are invested in the development and launch of new products, most of which fail (Dahl, Chattopadhyay, and Gorn, 1999; Goldenberg, Lehmann, and Mazursky, 2001). It is argued that one of the several reasons for new-product failure is the absence of creativity (Sethi, Park, and Smith, 2001). Thus, understanding what makes a concept creative and how to cultivate creative ideation is especially crucial in the field of marketing. However, as Andrews and Smith (1996) argue, despite the importance of creativity in marketing programs, little is known about the factors that affect the generation of such programs; hence, marketing programs for many established products fall short in terms of creativity. Dahl and Moreau (2002) also note that empirical research examining the cognitive processes underlying the creation of novel product concepts is sparse.

WHY IS CREATIVITY IMPORTANT FOR ORGANIZATIONS?

Creativity and organizational innovation. The terms *creativity* and *innovation* are often used interchangeably. But even though the two constructs are conceptually related, it is important to distinguish between them. Creative performance refers to products and ideas produced at the individual level, whereas innovation refers to the successful implementation of new products at the organizational level (Amabile, (1988, 1983); Oldham and Cummings, 1996; Zhou, 2003). Innovation

occurs when something new – something that has not been used or considered previously – is introduced to the organization. An innovation is a new artifact, product, system, technology, or process that has been successfully implemented in the organization.

Creative ideas or products do not always result in innovation. As Shalley, Zhou, and Oldham (2004) note, creativity refers to the development of novel and useful ideas, but only when these ideas are implemented successfully at the organization, can they be considered as innovations. Similarly, to introduce an innovation, the organization does not necessarily have to encourage or depend upon creativity – organizations can adapt products or processes that originated outside the organization (Woodman, Sawyer, and Griffin, 1993). Finally, sometimes an innovation is not surprising, nor original – it is just superior in some way. Innovations may represent an expected step in the evolution of a product, or may simply be moderately new.

Why is it important to study creativity to understand organizational innovation? As research often indicates, many innovations originate in creative ideas of individuals. Thus, although it is neither necessary nor sufficient, creativity is often the first step, the building block, of innovation (Amabile, (1988, 1997); George and Zhou, 2001; Tierney and Farmer, 1999; Zhou, 2003). Creativity is one of the major resources for innovation.

Organizational approaches to creativity enhancement. Past research on creativity often explored the impact of organizational-level constructs (e.g., organizational climate, Amabile *et al.*, 1995; perceived support, Scott and Bruce, 1995; presence of others, Shalley, 1995; goal setting, Shalley, 1991) or constructs reflecting stable individual differences (e.g., personality, Oldham and Cummings, 1996; problem-solving style, Scott and Bruce, 1995; intrinsic motivation, Amabile, 1997) (*see also* ORGANIZING FOR INNOVATION). However, more recently, researchers have argued that situational factors in organizations directly influence individuals’ creativity, and this influence is moderated by various personal attributes (Amabile *et al.*, 1995; Amabile, 1988; Oldham and Cummings, 1996; Woodman, Sawyer, and Griffin, 1993). As a

result, two main approaches were considered to potentially lead to creativity in the organization. An individual perspective focuses on creativity as a personal attribute that may characterize a person to some degree. By selecting creative individuals as their members, organizations can increase creativity of their products and services. A situational perspective focuses on situational factors that may influence creativity: various organizational factors (e.g., reward systems, organizational values, and norms) may work independently or combined together to increase creativity (Lee *et al.*, 2004). Organizations can therefore increase individual creativity by shaping the environment and employing socialization and training processes that generate a creative-friendly environment.

More recently, however, researchers have pointed to the importance of studying effects of the interaction between personal and situational factors (George and Zhou, 2001; Oldham and Cummings, 1996; see review by Shalley, Zhou, and Oldham, 2004; Woodman, Sawyer, and Griffin, 1993; Zhou and George, 2003). Thus, for example, creativity was found to be associated with job complexity (Baer, Oldham, and Cummings, 2003; Oldham and Cummings, 1996) and job autonomy (see also Amabile *et al.*, 1995; Shalley, Gilson, and Blum, 2000 who focused exclusively on situational variables; Zhou and George, 2001).

Does creativity contribute to product success? Not only does creativity play a central role in the potential of firms to innovate, it also enhances their competitiveness in the global market (Miron, Erez, and Naveh, 2004) (*see also SUCCESS FACTORS FOR NEW-PRODUCT DEVELOPMENT*).

To be original, a product, by definition, has to be different from what exists. Thus increasing originality is likely to lead to feelings of surprise (Derbaix and Vanhamme, 2003), an emotion that is experienced when the perceived object does not map on to expectations (Reisenzein, 2000) – in this instance, the norms for the category. The question is, does originality affect market success? It has recently been argued that creative products that are both useful and original should have a high correlation with

success and so they are expected to diffuse faster. However, so far there have not been any sufficiently convincing empirical results in favor of that argument. Contrary to what has been implied in the past (Carpenter, Glazer, and Nakamoto, 1994; Henard and Szymanski, 2001; Mishra, Kim, and Lee, 1996), originality alone may not be sufficient to ensure product success.

More directly, a meta-analysis by Henard and Szymanski (2001) showed that originality sometimes has a positive effect on performance and, at other times, the effect is negative. This led them to conclude that the effect of originality on performance is probably moderated by another unknown factor. Recent work by Derbaix and Vanhamme (2003) provides correlational evidence to suggest that feelings of surprise can lead to both positive and negative word of mouth (WOM). Thus, while increasing originality may lead to increasing levels of WOM, the valence of the WOM need not be positive; it can also be negative.

Goldenberg, Moldovan, and Chattopadhyay (2006) explored how new-product dimensions, specifically originality and usefulness, influence the WOM spread about the product and therefore its ultimate adoption and market size. They show that originality and usefulness have different roles in the adoption process of a new product, while originality amplifies both positive and negative WOM; usefulness determines the valence of WOM (positive or negative) and can increase market size. High originality, when combined with low usefulness, may produce high amounts of negative WOM and may lead to failure.

Another intervening factor that affects creativity's impact on product success may be timing. Being a first mover (Golder and Tellis, 1993) may not necessarily confer an advantage for a specific firm's strategy (Cooper, 1996; Lieberman and Montgomery, 1988, 1998). A follower advantage may be free riding, or even gaining a "gateway for a new entry" due to technology discontinuity. However the exclusive discovery of an emerging need is a commendable achievement and a necessary step toward a possible decision to take advantage of the opportunity to control market share through pioneering status.

DISCUSSION

Many legends have been told about cases in which a person had developed an idea as a result of a dream. One famous story appears in almost every book dealing with creativity. Friedrich August von Kekule, who discovered and defined the formula of the paraffin molecule, later tried to decipher the secret of the benzene molecule. After many years of incessant research and thinking, something happened in his life: as he was sleeping by the hearth; he dreamt of balls jumping in the form of a snake swallowing its own tail. When he awoke he understood that this was the secret of benzene: contrary to what he had formerly believed, the benzene molecule is not "linear," but "circular" (hexagonal, to be exact). The lecture he delivered at the ceremony commemorating his discovery ended with the words: "Let us learn to dream, gentlemen." Koestler (1964) called this incident "probably the most important dream in history since Joseph's seven fat and seven lean cows."

By contrast, there are evidences that an excess of ideas and analogies obstructs the ideation process, and randomness and disorganization impede creativity. It has been realized that total freedom in problem solving is inadequate (Connolly, Routhieaux, and Schneider, 1993; Paulus *et al.*, 1993; Stroebe, Diehl, and Abakoumkin, 1991). "It follows," says Boden (1992), "that constraints – far from being opposed to creativity – make creativity possible. To throw away all constraints would be to destroy the capacity for creative thinking. Random processes alone, if they happen to produce anything interesting at all, can result only in first-time curiosities, not radical surprises."

An important part of being creative is to know the "rules of the game" and to become skilled at applying them (Perkins, 1981). Simonton (1984, 2003) states that the creative genius is an expert in a given domain, and is well acquainted with its rules and regularities. However, even in the exact sciences one cannot apply fixed rules mechanically. According to Aristotle, the matter of the *practical* – by being variable, particular, and perceptual in nature – is essentially indeterminate or indefinite. Practical wisdom must therefore use rules only as summaries and guidelines. It must itself be flexible, ready for surprise,

prepared to see, and resourceful at improvisation or creativity (Kessels and Korthagen, 1996). MacIntyre (1977) aptly pointed to the interplay between *rule following* and *ruletranscending*: "Objective rationality is to be found in knowing how and when to put rules and principles to work and when not to. Because there is no set of rules specifying necessary and sufficient conditions for large areas of practices [such as creative advertising], the skills of practical reasoning are communicated only partly by precepts but much more by case-histories and precedents." The true work of the innovator consists in choosing among these combinations so as to eliminate the useless ones or rather to avoid the trouble of making them; and the rules that must guide this choice are extremely fine and delicate. It is almost impossible to state them precisely; they are (tacitly) felt rather than (explicitly) formulated.

Smith, Ward, and Finke (1992) note the existence of two distinct processing phases of creative thinking: a *generative* phase, followed by an *exploratory* one. These two phases are termed by Phillips (2005) as *inspiration* and *elaboration*. In Kelly's terms, there is a *creative cycle* of *loosening* and *tightening*. When being creative, we first *loosen* our constructions; then, finding a novel construction that seems to have some potential, we focus on it and *tighten* it, giving it substance or form (Kelly, 1955). An apparently similar rationale drives Barron (1969) to conclude that the essence of creativity is the ability to experience the extreme of psychological states – *crazy* and yet *sane*; in our view, creativity can be viewed as a constant oscillation between *surprise* and *regularity*.

product platforms

Marc H. Meyer, Olivier de Weck, and Tucker Marion

BASIC DEFINITIONS

It has been shown that a key to success is to leverage existing know-how and assets across existing products as well as new market applications (Meyer, Tertzakian, and Utterback, 1997). Designing, developing, and integrating “product platforms” is a tried and true practice for accomplishing that end (Meyer and Lehnerd, 1997). We first define the meaning and context for product platforms in new-product development, and then provide a method for planning product platforms and linking them to current or new-product portfolios.

Definitions for product platforming are very important because “platform” is now used in so many different ways. To establish a meaning that we find most useful in the practice of new-product line development, let us begin with Figure 1. That figure provides an approach for leveraging product platforms to current and new market applications in the form of distinct product lines with specific products (*see* PRODUCT-LINE STRATEGIES).

Market segments and applications. At the top of the figure is a representation of a firm’s current and potential target market segments, with a range of distinct *market applications*. A market segment is a specific group of users, made specific by virtue of classic segmentation criteria (geographic location, income level, gender, or industry affiliation) and behavior criteria (a high-performance user versus a price buyer, for example). Market applications are formed by applying potential product *uses* against these different users. A market application is therefore the intersection of specific groups of *users* and specific types of product *uses*.

In the figure, different market applications are labeled A, B, C, and D. Each represents distinctly different needs and user preferences and mainly requires different functionality in some shape or form in the products or services designed to address the target applications.

To illustrate, an automobile manufacturer can segment potential users in terms of age, gender, and family status – for example, as families, mature professionals, or young adults. These users then have different product uses: family driving, commuting to work, driving as part of a trade, or driving for social experience (the youth market). From the intersection of these users and uses come specific market applications: a family van, an upscale commuter car, a pickup truck, and/or a stylish sports utility vehicle (SUV) designed for Gen Y.

Product portfolio. The aggregation of all the products within the product lines intended to address a firm’s target market applications can be referred to as the firm’s *product portfolio* (Wheelwright and Clark, 1992; McGrath, 2001) (*see also* PORTFOLIO MANAGEMENT). In Figure 1, the product portfolio contains all the specific product variations within the product lines serving market applications A, B, C, and D. The product portfolio specifies different product offerings, typically at different price points, for different target applications – with an eye on beating competition, increasing demand, and achieving overall operating profit. These specific offerings can be arrayed on the same market segmentation grid. Rather than just “A” in the figure, a firm might offer several or more specific products for a specific market application. The firm might also not play in that market space because of competitive intensity or lack of market knowledge. Staging an entry into specific market applications over a period of years is another possibility.

Creating robust product portfolios requires deep insight into the needs, preferences, and aspirations of different potential types of customers (*see* VOICE OF THE CUSTOMER). The marketing goal of effective portfolio planning is that each element of the product portfolio brings complete satisfaction – an even better, delight to each specific target user and his/her intended product use along the price/performance/feature or capability continuum. Portfolio planning should also establish the clear streams of revenue derived from specific product offerings for target market applications. In other words, the product portfolio becomes a revenue map.

Market applications

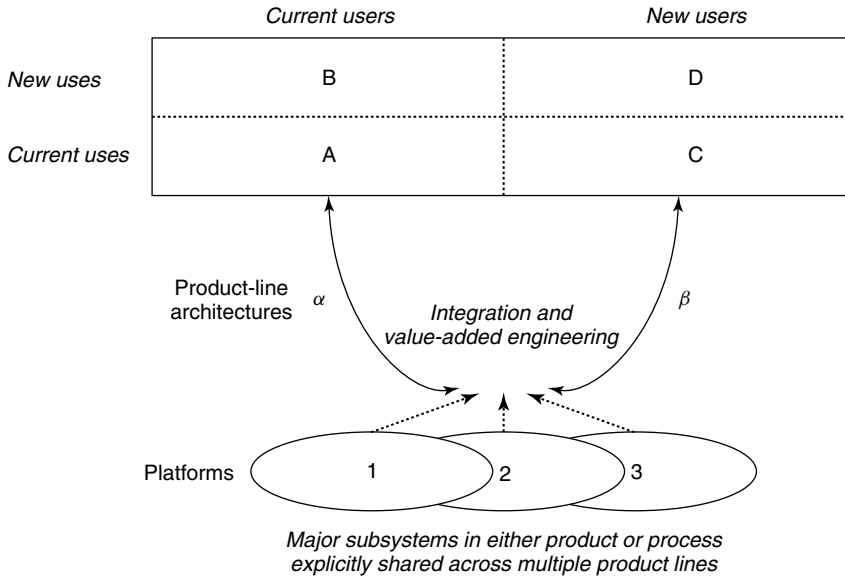

Figure 1 Leveraging platforms to new market applications.

Product-line architecture. Figure 1 also represents a firm that applies major common subsystems to its different market applications. An example might be a common engine across different passenger automobiles and sports utility vehicles (Honda), or a common database management system serving different software modules within enterprise bookkeeping and customer management (SAP). The ability to leverage these common subsystems relies on a clear architecture for each product within the product portfolio. That architecture defines not only all the subsystems but also the interfaces between these subsystems.

Robust product-line architecture allows an engineering team to combine subsystems common to the entire product line with subsystems that are unique to specific product variations in a manner that is both effective and efficient. It also allows a team to produce different levels of functionality within the product line without reengineering each individual offering – typically seen as “good, better, best” variations derived from the same product-line architecture (Meyer and Lehnerd,

1997). In addition, a product-line architecture may in fact span multiple market applications – A, B, C, and D taken as whole in Figure 1 – or each market application may require its own unique product-line architecture.

In Figure 1, we show two product-line architectures, labeled *alpha* and *beta*. These represent distinct configurations of subsystems and the interfaces between those subsystems required for the overall construction or assembly of products created from the product-line architecture. Continuing our example, Honda has distinct product architectures serving its Civic and Accord product lines, and another product-line architecture for its entry level SUVs, its large SUVs, and its minivans. A firm must periodically renew its product-line architectures to incorporate new technology breakthrough – such as using new hybrid engine technology in passenger cars.

Product platforms. *Product platforms* shown in the Figure 1 as 1, 2, and 3 represent specific modules of functionality. These are modules used within and across different product-line

architectures. A single subsystem shared across multiple products is considered a product platform, and across multiple product lines, truly powerful and robust. A product platform is an operational building block for a range of final products. For example, when a razor manufacturer develops a shaving blade of the same dimensions, coating, and edge for different products, it has created a powerful product platform. The same user interface across a suite of software products brings complete satisfaction to the user, simplifies training, and decreases switching costs (Cooper, 2004).

A product platform can also be an interface between different subsystems within a product-line or multiple product-line architectures. In software, .Net is a product platform enabling distributed computing in Microsoft's own operating systems, database, portal, and content management tools, its Office application suite, and third-party software products. Common product platforms – the core subsystems within an architecture and the interface between these and other nonshared subsystems – lead to efficient use of engineering resources, economies in materials purchase, and more rapid cycle time for developing new products that can use the common building blocks.

Process platforms. The manufacture, assembly, or fulfillment of a product platform is typically creating a shared asset that is used to produce different specific products within a product line (see also PROCESS INNOVATION). That shared asset may be considered a *process platform*. Common process platforms lead to substantial advantages in terms of capital for plant and equipment (where costs are shared across multiple product lines), as well as efficiency and learning in actual production. For example, Honda uses the same assembly line for manufacturing its Civics passenger lines and Element sport utility vehicle; and Mars, Inc. produces its heart-healthy CocoaVia chocolate bars on the same manufacturing asset as its Kudos snack bar (Meyer, 2007). Flexibility in the shared manufacturing asset to produce different configurations is an essential design goal (Hauser and de Weck, 2007).

WORKING WITH PRODUCT PLATFORMS: DEFINING FIXED POINTS AND FLEX POINTS WITHIN A PRODUCT-LINE ARCHITECTURE

Figure 2 shows how a team can think about the combination of product platforms with other subsystems within a product-line architecture. In the figure, each product line has its own distinct product-line architecture (defined as the major subsystems and interfaces that are the foundations of all the specific products within that product line of business). Over time, that architecture evolves to meet new user requirements and embrace new core technology. In the figure, that architecture is depicted as layers of subsystem technology – some common, others unique, to specific product lines within the product portfolio.

In platform-focused firms, the value-added engineering performed for individual products is a portion of the total engineering effort, because the most of the technology for single products comes from common existing platforms. The power of the platform discipline becomes evident when a substantial percentage of all the modules within and between product-line architectures are common. There can be cases where the degree of commonality is 100%, and variation for different groups of customers is achieved through *services* provided with the product. However, it has also been shown that taking platforming too high up the stack can make differently branded products look and function all too similarly – saving on cost of goods but disappointing users (Simpson, 2004). The more typical scenario, however, is that half or more of the engineering required for a new-product development within an established product line is achieved by the integration of preexisting subsystems based on preexisting interfaces.

With time, the functionality, performance, and cost of common subsystems are improved by the firm itself or its suppliers. Robust interface design allows engineers to migrate to increasingly powerful generations of subsystem technology without violating the overall product-line architecture. The ability to replace aging components with newer, better ones comes from effective technology roadmapping (Albright and Kappel, 2002).

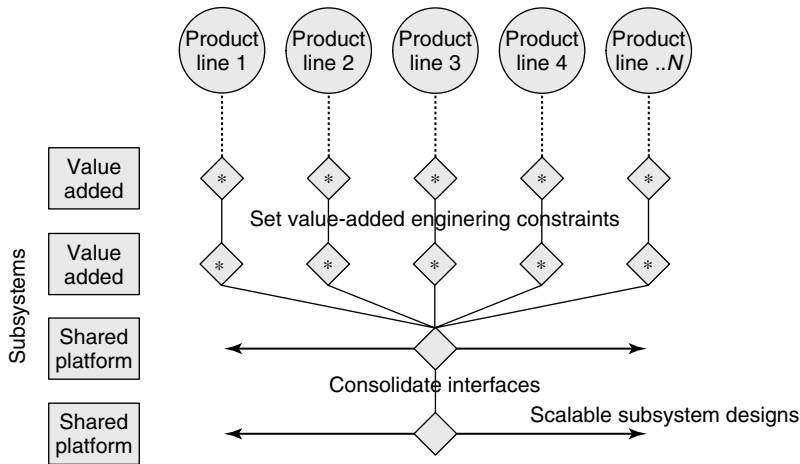

Figure 2 Fix points and flex points in design: combining common product platforms with unique subsystems.

Interface discipline is essential for successful product platforming (Boothroyd and Dewhurst, 1987; Sundgren, 1995; Cooper, 2004; Meyer and Webb, 2005). This concept is represented by the words *single channel interfaces to and from subsystems* in Figure 2. This means one clear method or process for connecting to that subsystem from any other subsystem, clearly documented and strongly enforced. Unfortunately, as engineers add new functionality to other subsystems, they also tend to create new custom interfaces between these subsystems. Over time, a multiplicity of interfaces becomes a tremendous impediment to the innovation of a new subsystem and a value-added product development. Without interface discipline, it becomes increasingly expensive to make even the most incremental of product improvements. On the other hand, robust interface design can enable greater levels of product variation at minimal cost. For example, earthmoving equipment manufacturers, such as Caterpillar, have designed flexible coupling devices to rapidly attach different work tools (buckets, hammers, and forklifts) to the same machine – such as a backhoe loader.

PLANNING FOR SCALABILITY IN PRODUCT AND PROCESS PLATFORMS

The primary design requirement for a product or process platform must be the flexibility to

fit within different product-line architectures, and scalability, to support increasingly powerful products. This enables a firm to efficiently leverage these common modules – its product platforms and the production processes for them – to new market applications. The process of mapping specific product platforms, with varying levels of functionality, to specific products is well described by Thomson and Broms (2000) with the example of how Scania designs its trucks.

Defining the range of functionality for a common subsystem or interface, for example, the product platform, requires that a team first have a working definition of the product portfolio. That portfolio may include all the products planned with a single product line, or all the products planned for multiple product lines depending on the scope and focus of the development initiative (as represented earlier in Figure 1). With the portfolio in hand, the team must then carefully study user requirements in terms of performance, other types of functionality, and cost – typically arrayed as levels of performance/price within the product line(s) serving the target applications. These functionality requirements (see PRODUCT SPECIFICATIONS) may be strikingly different for different markets – male versus female; developed country versus emerging market; enterprise software versus home-use software

market. With requirements in hand, the team can then design its product platforms to serve its target applications. By achieving this, the team creates a *scalable* product platform (de Weck, 2006).

Figure 3 shows one classic instantiation of engineering a scalable product platform – in this case, a common motor that could deliver a broad range of power based on varying wire stack length, and which served levels of “good, better, best” for Black and Decker’s drills, sanders, jig saws, circular saws, and other major power tools product lines. Figure 4 shows a more recent example, Honda’s family of engines that have served “good, better, best” versions of both its passenger cars and sports utility vehicles. Scalable product platforms such as these, and their associated high-volume manufacturing processes, are powerful enablers to reduce cost of goods on a per unit basis and to meet rapidly expanding levels of demand for products in the line.

PRODUCT PLATFORMS HAVE IMPLICATIONS BEYOND PRODUCT AND TECHNOLOGY

Making the business case for product platforms is increasingly important in resource-constrained business environments where the benefits of a platform program must be weighed against more traditional single-product developments. Experience has shown that in many industries, it is initially more expensive to design and develop a robust, scalable product platform and its associated manufacturing processes. To be able to justify the benefit of the platform effort to the business, a team must develop a business case.

The business plan for platforming should aggregate operating profits projected for all products in the platform-based portfolio and use these aggregated sums in net present value and/or ROI calculations. A team might find, for example, that the investment required to develop platforms might be more than covered by the lower cost of goods from such commonality. However,

Figure 3 Black and Decker achieves magic with its scalable motors – the product platform shown incorporated in two of many product lines (reprinted from Meyer and Lehnerd, *The Power of Product Platforms*, 2007).

arriving at this type of detailed understanding of material and conversion costs for platform-based product lines requires a dedicated effort to do well. Clearly, a platform-planning team should include individuals with strong financial acumen who know how to gather cost information and integrate these with pro forma income statements and capital plans.

Breaking cost barriers typically requires a team to challenge the conventional thinking within the company in terms of manufacturing processes and suppliers. If a team is bold in its thinking, it can deliver more powerful products at lesser cost than the firm's current offerings, and its proposal to senior management becomes much more attractive. For example, it can recommend lower market prices for its new products, increasing market share or in fact enlarging the current market to generate substantially greater revenue. Or, a team might recommend maintaining current market share and more slowly growing revenues, but substantially improved gross margin. Regardless of the final business-case approach, we encourage all platform teams not to simply seek product parity at lower cost, but rather, *to create better products*

that can also be produced at lower cost. This helps achieve *value-cost leadership*, a foundation for sustained success (Meyer and Lehnerd, 1997).

Product platforms can also help a firm reconsider its business model. First, traditional premium manufacturers can apply platforming to lower their manufacturing costs, providing new mid-range or perhaps even low-end product offerings to match competition from offshore companies with lower labor costs. Many companies are at present considering platforming as a response to low-cost competitors who are scaling up their products to compete in mainstream markets. Second, platforming – particularly in software products – allows firms to create new streams of recurring revenue enabling plug-in modules for the installed base. Third, platforms can have beneficial effects for a firm's service business. Rather than training service staff on the inner workings of the many different subsystems and interfaces across an entire portfolio, a product line with shared subsystems allows economies in training and service delivery. Lastly, the design of services can themselves be platformed (see SERVICE INNOVATION MANAGEMENT),

focusing on common processes and measurements of quality and cost for those processes (Meyer and DeTore, 2001).

A business case must also consider that well-designed product and process platforms enable future innovation by providing a stable base upon which technology could be applied to create new market applications. Modifying the “flex points” and leveraging the “fixed points” within a product-line architecture is the key to creating niche-focused products at little cost and readying them for market testing. While one cannot fully anticipate the range of product variations in future years, the flexibility to respond to market opportunities should interest any forward thinking senior management team. Creating rich variety from simple means is a grounding principle of platform strategy.

There are, of course, many inspirational examples of successful platform management leading to business success. These include Honda, the different vehicles of which share power trains, and Boeing, whose 787 Dreamliner leverages scalable frame, cockpit, and interior subsystem technology across a broad range of formerly separate aircraft. Apple is another fine example. The iPod, iTunes, and iPhone products share common operating systems and applications software platforms – including iTunes. Apple also broke tradition by making its iTunes software operational on Windows-based computers to broaden market reach. Aspiring to be like Honda, or Boeing, or Apple, however, is of directional value only; it is up to each company to determine how these principles apply best to its own specific situation. There are no short cuts.

To sum up, product platforms have intriguing implications that go well beyond products and technology. Readers must consider these to achieve business as well as technical success. Books such as *The Fast Path to Corporate Growth* (2007) and *Product Platform and Product Family Design: Methods and Applications* (2006) provide detailed methods for platforming new product lines and many examples of success.

global product development

K. Sivakumar

INTRODUCTION, DEFINITIONS, AND ORGANIZATION

For our purposes, the word “global” means that the business activities of a firm span more than one country and, typically, several countries. We use the words *global*, *international*, and *cross-cultural* to denote similar concepts. Although the burgeoning growth of communication technology has resulted in what Friedman (2005) calls a *flat world*, in which location does not matter, globalization does have a spatial connotation. From a broader perspective, globalization encompasses variables such as language, culture, and time-zone commonality, as well as security issues. Globalization can manifest itself in several different ways: sales, sourcing, manufacturing, assembly, processing, accounting, and similar activities.

“Product development” refers to the process of conceiving of and creating a new product (Crawford and Di Benedetto, 2006); all new products must be “conceived, tangibly developed, and finally produced and sold in the market place” (Nakata and Sivakumar, 1996, p. 62). Product development involves several stages. The often interrelated stages can range from a two-part conceptualization of initiation and implementation (Zaltman, Duncan, and Holbek, 1973) to more than 10 stages, depending on how finely scholars want to categorize the different elements involved in product development (see THE STAGE-GATE IDEA TO LAUNCH SYSTEM). The outcome of product development is either a radical innovation or an incremental innovation. One way to conceptualize the innovation is a series of S-curves (Foster, 1986). Rising S-curves represent reduced costs and/or increased benefits along a given S-curve. Moving across the S-curve is radical innovation and moving along a given S-curve is incremental innovation (see TECHNOLOGY S-CURVE).

We define global product development as “a single, coordinated product development operation that includes distributed teams in more than one country utilizing a fully digital

and connected collaborative product development process” (Eppinger and Chitkara, 2006, p. 23). “Product” is an omnibus term that includes goods (e.g., digital cameras) and services (e.g., customer service at call centers), including knowledge-based services (e.g., software development, pharmaceutical drug discovery) (see INNOVATION TYPOLOGIES).

The article is organized as follows. First, the antecedents and drivers of the increasing trend toward global product development are discussed; second, some major themes and domains of knowledge on the topic of global product development are highlighted; third, research on strategies for achieving success in global product development are delineated; finally, implications for research and managerial practice, including emerging opportunities and challenges in the domain of global product development, are discussed.

By definition, global product development is a multidisciplinary activity (see CROSS-FUNCTIONAL TEAM). Therefore, existing knowledge on the topic comes from various fields, including marketing, management, economics, research and development (R&D) management, international business, and management information systems. As Kleinschmidt, de Brentani, and Salomo (2007) note, the product development and globalization bodies of literature have been developing over the past several decades as extensive but separate streams, and there is a need to integrate the research in the two domains given the rapid increase in global product development. Given the space constraints here, the goal is to highlight some salient, representative, and emerging themes in this domain rather than to attempt to provide comprehensive coverage.

DRIVERS OF GLOBAL PRODUCT DEVELOPMENT

Globalization is an important trend of the modern world that will define our activities for several decades into the future. There are several manifestations of enhanced globalization, including the world’s becoming “flat” (Friedman, 2005), the globalization of companies and customers, permanent or temporary movements or migrations of people

2 global product development

across countries, and the establishment of global monitoring organizations such as the World Trade Organization. There have always been debates among social scientists, policy makers, politicians, and academics about the appropriate level of globalization, the positive and negative effects of globalization, and related issues. Without taking a political position on the desirability or extent of globalization, it is clear that globalization is inevitable and that individuals and organizations are better served when they understand the antecedents, processes, and consequences of this trend, which enables them to exist and thrive in an increasingly complex and turbulent world. Global product development is one such inevitable manifestation in the operations of companies around the world. As Kleinschmidt, de Brentani, and Salomo (2007) argue, firms must commit to an integrated strategy of globalization and new-product development to be competitive in a business environment characterized by turbulence.

There are several trends that can be considered responsible for the increasing growth of global product development. First, the rapid globalization of companies, markets, and the employment base has led naturally to the globalization of product-development activity. Second, an increasingly educated workforce in developing countries such as India and China makes it convenient for companies to tap a wider pool of talent for all company operations, including product development. Third, intense competition in the marketplace and the need to reduce product development times provide an impetus for companies to use all available global resources to meet global customer needs. Fourth, the growth in information technology facilitates the knowledge development and sharing involved in new-product development across national borders (*see* LOCALE OF INNOVATION).

From media coverage and anecdotal evidence, it is clear that global product development is a phenomenon that pervades a wide range of industries, including computers (e.g., IBM), software (e.g., Microsoft), manufacturing (e.g., General Electric), consulting (e.g., Accenture), and pharmaceuticals (e.g., Merck). Although large multinational companies engage in global product development as a natural

manifestation of their globalization, small and medium-size companies are involved in the process as well: as partners in strategic alliances, as upstream suppliers, or as downstream customers.

Also, countries such as India are leveraging human intelligence and knowledge rather than low-cost labor, which has been the traditional way to participate in international business. In addition, there is a qualitative change in the way globalized activities spur global product development; for example, in India plants that simply produce products according to specifications have a lesser role to play in product development than do dedicated design centers and R&D labs (*see* RESEARCH & DEVELOPMENT).

THE NATURE AND SCOPE OF GLOBAL PRODUCT DEVELOPMENT

The scope of global product development varies depending on the nature of the product development task, including the time span, the degree of newness of the product, the number of people involved, and the importance of the product to the entities involved. At the low end, this might mean a small team of members from two units of a company in two different countries working together for a short-term, specific project to make a minor improvement to an existing product. At a more involved level, this might mean a large team from a network of companies working with their respective customers and suppliers in different tiers using elaborate communication and control systems to develop a radically new product that spans several years. Clearly, most global product development activities fall between the two extremes (e.g., a firm conducting its global new-product development with several subsidiaries via offshoring; a firm collaborating with an arm's-length foreign supplier and a local support office in a foreign country; a firm working to perfect a drug compound with an R&D unit in a foreign country; a firm's foreign subsidiary making a strategic new-product development alliance with another company to use its engineering or design capacity).

Therefore, the integration of company cultures and the integration of national cultures become important. For example, within-comp-

any global new-product development in a company such as IBM with operations in several countries represents fewer company culture differences and more national culture differences; global new-product development undertaken by a consortium of companies in two countries (e.g., the United States and the United Kingdom) represents more company culture differences and fewer national culture differences. Other nuances can be identified according to the nature of cultural difference (e.g., the cultural difference in a Canada–United States activity would be less than the cultural difference in a United States–India activity). The number of control systems that need to be established also varies on the basis of the type of product being developed and the nature of the relationship between the companies.

Much of the existing academic research has examined the process of product development (Crawford and Di Benedetto, 2006), and some of the core processes and routines carry over to global product development. Subramaniam, Rosenthal, and Hatten (1998) examined the processes and routines that firms use in global product development. They find that the processes that global companies follow (e.g., team composition) vary in the extent of the involvement of overseas subsidiaries. They also found industry-specific differences in how firms manage global product development. In particular, the authors found that with tacit knowledge about new-product design elements, firms employ cross-national teams and make use of overseas subsidiaries in the concept-development stage.

Business relationship factors such as buyer–seller interactions have significant influence on new-product development (Roy, Sivakumar, and Wilkinson, 2004). The buyer–seller factors become much more complicated in the context of global product development. Some of them may be simply a matter of scale (e.g., a larger community of practice), while others may represent qualitative differences (e.g., the extent and duration of communication moderated by the cultural dimensions).

THE ROLE OF NATIONAL CULTURE IN GLOBAL PRODUCT DEVELOPMENT TEAMS

Almost all new-product development activity is carried out primarily by teams. Global new-product development teams were once considered the “next wave of corporate development” (Solomon, 1995, p. 50). “Like their domestic-only counterparts, global new-product development teams are typically cross-functional, commissioned to design and launch new products, and face significant budget, time, and other resource constraints. However, global product development teams are different in that members usually come from a range of countries and cultures. Values, orientations, and assumptions may radically differ among members” (Sivakumar and Nakata, 2003, p. 397). McDonough, Kahn, and Barczak (2001) found that more than half of the companies that they surveyed used globally dispersed teams in their product-development effort, a trend that is expected to continue. Global product development teams typically face greater challenges than do colocated teams (McDonough, Kahn, and Barczak, 2001). An important defining variable in this context is *national culture*, which is defined as the “collective programming of the mind which distinguishes the members of one group or category of people from those of another” (Hofstede, 1994, p. 4).

There are different conceptualizations of culture. Among the more popular and empirically based are those based on the work of Hofstede (1980) and his coresearchers. Nakata and Sivakumar (1996) examined the role of individualism, power distance, masculinity, uncertainty avoidance, and Confucian dynamic on the initiation and implementation stages of new-product development. They conclude that different national cultural dimensions have different effects on new-product development. For example, individualism facilitates the initiation stage of new-product development but inhibits the implementation stage. The effect of power distance, masculinity, and uncertainty avoidance are the reverse (higher levels of these factors impede the initiation stage but facilitate the implementation stage). Because of cultural differences, attention must be paid

4 global product development

to the design of global product development teams (Sivakumar and Nakata, 2003). The composition and management of a team must take into account factors such as the differential effect of cultural dimensions on the different stages of the new-product development process and the relative importance of the different stages in a given product-development task (Sivakumar and Nakata, 2003). Song and Parry (1997) have found that, although multicultural teams lead to more creativity and problem solving, communication breakdowns can occur, and the team leadership's responsibility in this domain becomes important.

The national culture dimensions also can influence other aspects of global product development such as R&D-marketing integration mechanisms. For example, Garrett, Buisson, and Yap (2006) argue that with high uncertainty avoidance, firms will rely more on formal planning and control tools to avoid uncertain situations.

KNOWLEDGE MANAGEMENT IN GLOBAL PRODUCT DEVELOPMENT

Clark and Fujimoto (1991) state that product development is an activity to reduce uncertainty because it generates and uses new knowledge; therefore, new-product development can also be visualized as information processing of organizations.

Clearly, product development is a knowledge-intensive process that involves constant accumulation, dissemination, and use of existing knowledge and the creation of new knowledge. New products involve new knowledge or information assets (Clark and Fujimoto, 1990). Whether the product-development task results in incremental innovation or radical innovation based on the new knowledge created (Tushman and Anderson, 1986), an important challenge in global product development involving different firms is knowledge management in general (Söderquist, 2006) and the management of intellectual property in particular (Roy and Sivakumar, in press) (*see* INTELLECTUAL PROPERTY RIGHTS). In addition, leveraging learning in the product-development process is complex, and attention must be paid to organization development and training (Duarte

and Snyder, 1997). Knowledge management functions in global product development must recognize that different methods, such as a central knowledge management function, a project-decentralized knowledge management task force, and functionally located knowledge management cells all have different advantages and disadvantages, and that the optimal method depends on various internal and external factors related to the organization and the environment (Söderquist, 2006). Although the mix between tacit knowledge and explicit or codifiable knowledge is different across product-development tasks, the mix always involves challenges of knowledge management.

Given the complexity of structures, legal processes, and government regulations associated with global product development, the challenges of intellectual property management are unique. As Roy and Sivakumar (in press) point out, appropriate management of access, exploitation, and defense of intellectual property is governed by the extent of trust in the process and the amount of formal and informal control systems in place. By effectively managing intellectual property, firms will be able to achieve success in the generation of radically and incrementally new products (Roy and Sivakumar, in press).

PERFORMANCE AND EVALUATION ISSUES IN GLOBAL PRODUCT DEVELOPMENT

The implicit objective of each firm is to optimize the performance of global product development to achieve long- and short-term success (*see* SUCCESS FACTORS FOR NEW-PRODUCT DEVELOPMENT). Crawford and Di Benedetto (2006) offer unique guidelines for evaluating a new-product development program. Such evaluations can be used for global product development and modified to account for the nature and scope of global product development. In general, the conventional measures of effectiveness and efficiency (e.g., ratio of new-product sales to total sales, product-development cycle time) can also help assess the performance of global product development, and many of the factors that govern the performance of product development in general influence the outcome of global product development.

Given the increased scope and complexity of the global product development process, some new challenges may arise. For example, when most of a new product's sales growth occurs in one or two countries, how should the firm understand the relative role of new-product sales of the global corporation? How can the differences in people's use of attitude scales across countries be reconciled with differences in the evaluation of people's assessment of new-product development programs?

There are some guidelines available from existing research on factors that influence global product development performance. The information-processing perspective of global product development implies that the fit between uncertainty and information-processing ability directly influences performance (Subramaniam, Rosenthal, and Hatten, 1998). Kleinschmidt, de Brentani, and Salomo (2007) found that performance in global product development is determined by organizational new-product development resources and new-product development process capabilities. Several researchers also offer operational guidelines for managing global product development. For example, Barczak and McDonough (2003) focused on effective ways to manage product-development teams and found that initial face-to-face meetings, increased communication among team members, and periodic progress meetings facilitate the success of global product development efforts. Wren, Souder, and Berkowitz (2000) studied the link between market orientation and product development in global firms. They found that both market intelligence gathering and customer orientation are related to superior new-product development performance. In addition, different cultural dimensions can have different influences in the performance of different stages of global product development (Nakata and Sivakumar, 1996).

MANAGERIAL AND RESEARCH IMPLICATIONS

Although the phrase "necessity is the mother of invention" is often used as a cliché, the current economic, political, and security situation around the globe is likely to result in innovations in global new-product development

procedures and processes. The following are some examples.

The differences in complexity between intra- and interfirm relationships involved in global product development will overlap considerably and become governed by interactions. For example, a scenario of constant interaction between two US companies may involve less complexity than the interaction between the US headquarters of a company and a branch unit in India or China, especially if there is frequent change of personnel in the branch office.

Second, although both codified knowledge and tacit knowledge are required and processed during global product development, improved information technology and communication devices will trend toward even more codified and routinized tacit knowledge. Relatedly, management of intellectual property will offer its own challenges.

Third, new advances in improving global product development are likely to come about in the case of knowledge-based services. Given the cultural differences among employees and customers, and the evolving nature of the knowledge economy, it is surprising that the political discourse in the United States (particularly during election time) is still dominated by the manufacturing economy, although we have long since moved from a predominantly manufacturing economy to a service economy and now even toward a knowledge economy. It will be a challenge for professionals to influence the public discourse to be consistent with the future-oriented evolution of the economy and the attendant new-product development process.

Similarly, the sensitive nature of globalization (represented by the phrase *outsourced jobs*) must change from an attitude of "us" versus "them" to mutual coexistence based on competitive advantages, local conditions, and process capabilities. Breaking down the barriers will invariably equalize the playing field, bring in more nuanced specializations as marketable resources, and bring about creative methods of collaboration.

Finally, for global product development, the company must recognize the global customer and also realize that there are no more isolated markets in the world. Ultimately, global product

development is the domain that can effectively link people with knowledge, in addition to the traditional forms of monetary exchange or manufacturing facilities, as a resource.

CONCLUSION

Global product development represents the intersection of the two most important business activity domains in the foreseeable future. Although the nature of global product development can be considered an extension of product development in general and some of its aspects may be similar to traditional product development (e.g., the types of activities undertaken, the need for multidisciplinary teams), the complexities and nuances of global product development can be very different (e.g., modes of communication, number of people involved, location of different teams, cultural differences). Firms must proactively address such complexities and nuances. Increased global product development will result in the evolution of the locus of the product-development activity, the types of products being developed, and areas in which the products are registered and marketed. Thus, there will be a need to focus on the global dimension in all product-development research and practice.

pretest market models

C. Anthony Di Benedetto

A consumer-goods marketer, seeking to commercialize a new product, needs to gather market information to support the launch decision, and also to fine-tune the marketing mix (*see* LAUNCH STRATEGIES). In the past, a product manager may have tried a test market (*see also* PRODUCT TESTING), in which the product is sold in real stores under real conditions over a length of time, allowing adjustments on several components of the marketing mix. Full-scale test markets are, however, costly and time consuming, and also carry their own risks. Competitors can monitor test markets and launch their own version of the product and have even been known to sabotage test markets (by, for example, dropping valuable coupons of their own brands into the test market area). While managers still occasionally conduct a lengthy, full-scale test market for new products, they typically start with a research method that provides good quality information on customer response in a much shorter time and at much less cost. This allows the manager to screen out likely failures, before investing in the costlier test market or other market testing procedures.

One of the most common forms of market test used at this stage is the pretest market (PTM), or simulated test market. As the name implies, PTMs attempt to simulate the customer's purchase behavior in a controlled setting. The cost and time requirement is substantially lower than for a full-scale test market, and the manager avoids revealing early information about new launches to competitors.

HOW PRETEST MARKETS WORK

Managers were seeking alternatives to test markets years ago, and early work on PTMs was initiated as far back as the 1970s by market research firms such as SAMI/Burke (now part of ACNielsen) and BBDO. These, and other well-known PTMs such as ASSESSOR, all have at their core the awareness-trial-repeat or ATR model. In other words, the forecast long-term market share of a new consumer product is the product of its ultimate cumulative

trial rate and its repeat purchase rate. In its simplest form, if a cereal producer can get 25% of the market to try a new brand, and of those, 5% become repeat purchasers, the long-run market share is projected to be $25\% \times 5\% = 1.25\%$. This, of course, assumes that all potential customers are aware of the new brand, so this would have to be adjusted for the level of awareness the brand would achieve with expected advertising expenditures. The advertising agency working on the account may provide estimates on awareness, while other factors such as availability, prices, and costs may be provided by the product manager.

In addition to time and cost savings, another major advantage of PTMs is the level of confidentiality obtained by the firm. Typically about 300–600 customers may take part, and although procedures differ, most PTMs involve exposing the customer to the product (and perhaps pricing information and advertising), assessing likely trial rates, providing the customer with a sample to try at home, and following up later to determine likelihood repeat purchase. PTMs are commercially available for use by consumer-goods manufacturers, and typically provide customer information within about 14 weeks, with costs in the range \$50 000–300 000 or more, depending on complexity (Crawford and Di Benedetto, 2008, p. 436).

The PTM not only provides information on the likely success of a new product but also helps diagnose where the trouble areas are. For example, if a market share is predicted to be low, it may be due to low trial and/or low repeat. A PTM will help management identify the culprit, and then take action. If trial is projected to be low, it may require that advertising copy or pricing levels be adjusted; if repeat rate is low, management may focus on why customers are so quick to switch away from the brand.

PRETEST MARKET PROCEDURES

Several PTM suppliers are available: two are profiled here (ASSESSOR and BASES) because these are prominent examples of each of two broad categories of PTM procedures. Both categories begin with customer trial and repeat data, but differ in the way these data are used to derive sales forecasts. ASSESSOR is typical of PTMs

2 pretest market models

that use mathematical models to generate the forecast, while BASES is an example of a PTM that uses a heuristic approach (a comparison against previous similar products). An in-depth discussion of both ASSESSOR and BASES is provided by Dolan (1992). Several other PTMs exist, and a good description of some of the classic ones are provided by Shocker and Hall (1986) and Urban and Katz (1983).

*The ASSESSOR model*¹. The ASSESSOR model, originally developed by Silk and Urban (1978), seeks to simulate the new-product introduction process in a compressed time period (typically, well under six months). Suppose a well-known soup company is planning a new brand launch. The procedure may begin with a mall intercept or a series of phone calls, in which respondents are asked to participate in a research study. After a brief interview to determine demographics and marketing data such as category usage status (i.e., heavy, light, or no soup consumption), respondents enter a research facility and are exposed to print or broadcast advertising, for the new soup as well as several other products. The advertisements may even be placed within the context of a new TV pilot program that is itself also being tested by the network. (Procedures vary here, depending on the research agency.)

Next, the respondent moves to a mock store aisle, is provided with some cash and asked to go shopping. The new soup is, of course, one of the products in the store aisle, and the research agency may take this opportunity to try different price points or shelf locations for the soup being tested. The respondent can purchase whatever he or she wishes, and can keep the remaining cash. If the respondent did not buy the soup, then a sample of it is given as a “thank-you” gift; in any event, all participants walk away with the product in hand. A sample of respondents may be asked to stay a few more minutes, to respond to a questionnaire regarding product usage, attitudes toward the brand, and so forth. This procedure provides management with a quick assessment of likely trial, and how trial may be affected by price levels, advertising exposure, and so on.

There are variations on the above procedure. One research agency, for example, replaces the mock store with a series of purchase intention

questions, and simply would give the soup to all respondents who express an interest in it.

To get a measure of likely repeat, the research agency contacts the respondents several weeks later to see how well they liked the soup. The wait time depends on the product category; if it is an item that is consumed relatively slower (like toothpaste), the agency may wait longer to call. The researcher assesses customer’s product usage, positive or negative reactions, and intentions to purchase the soup in the future. The repeat rate is adjusted on the basis of this postuse data, and accounts for the possibility that customers will switch away from this brand, or switch from a competitor to this brand, in the future. To be precise, then, the repeat purchase rate here is actually an estimate of share of subsequent purchases.

Assessed trial and repeat rates are then multiplied to obtain a raw equilibrium market share. This raw market share is then adjusted down to account for projected levels of awareness and availability, to arrive at the final ultimate market share forecast. The ASSESSOR model contains a validity check on this forecast, which involves measuring customers’ preferences among the different brands of soup.

ASSESSOR tends to predict market shares quite accurately. According to Urban and Katz (1983), actual performance was compared to ASSESSOR predictions, and the predictive error in the forecasts was 21.5%. However, many of the gaps between predicted and actual market share were because of changed conditions (for example, anticipated levels of awareness and distribution were never reached). After adjusting for these discrepancies, the predictive error declined to only 11.6%.

The BASES model. BASES, originally developed by SAMI/Burke, is another popular supplier of PTMs. BASES has many distinguished consumer-goods business units among its clients, including Colgate-Palmolive, Frito-Lay, Gillette, Procter & Gamble, and many more (Dolan, 1992). The BASES procedure is not too different from that outlined above for ASSESSOR. Usually, respondents are obtained through mall intercepts, shown a new product concept, and asked questions regarding their likes and dislikes regarding the

product, perceived value, and likelihood of purchase. Respondents who show an interest in the product are allowed to take some home with them, and later phone calls assess satisfaction levels with the product as well as likelihoods of repeat purchase. Unlike ASSESSOR, however, which uses mathematical modeling to convert this information to market share projections, BASES uses a heuristic approach. Very simply, BASES has a database of thousands of prior PTM studies. They select data from comparable previous product introductions, and use these data to calibrate raw trial and repeat scores. These adjusted data are then run through an ATR model to develop the sales forecast. Another heuristic model, NEWS, developed by the advertising agency BBDO, does not rely on data from previous product introduction, but rather uses survey data derived only from the brand under study (Pringle, Wilson, and Brody, 1982).

Like ASSESSOR, BASES has established a good forecasting track record. According to Dolan (1992), Burke claims that 90% of their sales, trial, and repeat forecasts are within 20% of the actual levels, while over half are within 10%.

NEW TRENDS IN PRETEST MARKETS

We are now starting to see applications of PTM models in the forecasting of consumer durables and business-to-business products. General Motors, for example, has been using a new measurement method known as *information acceleration* (IA) to assess purchase intentions of new cars (Hauser, Urban, and Roberts, 1990). In IA, respondents enter a virtual buying environment that simulates, in this case, the car purchase situation. They interact with virtual salespeople and hear word of mouth from virtual customers, they see print and broadcast ads, and can even virtually walk around the car showroom to look at computer prototypes of new models.

Consumer goods can also be virtually tested, as in the visionary shopper (VS) procedure. In VS, the respondent enters a virtual store and can “shop,” read labels and price information, and make purchases, all by touching the computer monitor. Companies are increasingly using VS or

similar virtual-testing procedures as an important part of the PTM process (Burke, 1996; Rosenberger and de Chernatony, 1995).

CRITICISMS OF PRETEST MARKETS

PTMs have received their share of criticism. The mall intercept or related techniques essentially create a laboratory experiment environment (that is, people know they are being tested). In addition, the mock store aisle is clearly not the real thing, and the advertising stimuli are presented in what some say is an unrealistic way. It is possible that these false conditions make the results suspect. PTM suppliers argue, however, that few other methods can provide good quality forecasts in such a short time. Nevertheless, there still are drawbacks. We saw earlier that the forecasts will be only as good as the projections of awareness and availability (as well as other projections) that come from management; another problem is that only final consumer response is considered. Our soup manufacturer might find that the new soup brand scores high in PTMs with consumers, but unfortunately is not liked by retailers (maybe the newly designed cans are hard to stack and fall off the shelf?) and therefore they refuse to carry or promote it. In addition, PTMs might have less value for new-to-the-world products, or for products that are not sold via personal selling or point-of-purchase promotions (Crawford and Di Benedetto, 2008, p. 439).

idea management

Jeffrey Baumgartner

INTRODUCTION

Idea management is a structured business process for capturing focused business ideas from a population, typically the employees of a company, and evaluating those ideas to identify the most promising ones. The process is typically facilitated by an enterprise software application with a front end for the submission of ideas and a back end where those ideas are reviewed. The front end, usually a set of web pages, is open to a large group that may consist of some or all employees of a company as well as, in some instances, business partners, customers, stakeholders, and others. This group typically numbers several hundred people, although some applications permit thousands of users. The back end normally may only be accessed by managers who will use the evaluation tools to determine which ideas should be promoted for implementation.

In addition to the software, substantial human intervention from the idea management team – in other words, the person or people overseeing the process in a given organization – is critical to an effective idea management initiative. Promotion of innovation and the idea management process, senior management buy-in, a good communication plan, and a rewards scheme are among the actions that help make an idea management initiative a success. And, although it may seem obvious, the final step of an effective idea management initiative is the profitable implementation of the best ideas.

Although idea management is considered an innovation process, it is arguably more of a CREATIVITY tool. Idea generation is a creative process and, as we shall see, most viable idea management systems are based on creative problem solving (CPS) methodology.

If idea management sounds a lot like a modern suggestion box, that is not surprising. Not only is the process arguably derived from suggestion schemes but many firms still use a variation on the suggestion box as the basis for their idea management process. However, as we shall see, this is not usually an effective approach.

SUGGESTION SCHEMES

The predecessor to idea management was the suggestion box, which is essentially the front end of a suggestion scheme. A suggestion scheme is a simply structured approach to capturing ideas. A suggestion box, or other repository, is set in a public space within an organization. Employees are invited to submit suggestions. Periodically, management reviews the submitted suggestions and decides on which ideas to implement.

The first recorded use of a suggestion scheme was by the Japanese Shogun in 1721, who offered awards for ideas (Beddows, 2001). The British Navy implemented a suggestion scheme in 1770 as a means for allowing all their personnel to offer suggestions without fear of consequences. At that time, any suggestion that contradicted the thinking of a senior officer was subject to reprimand and, in extreme cases, hanging (Robinson and Stern, 1998)! The first suggestion box and structured suggestion scheme were implemented in 1880 at the Scottish shipbuilder William Denny and Brothers (Beddows, 2001).

Suggestion schemes have persevered over the centuries, with many companies providing them for employees as well as customers. With the dawn of the web in the early 1990s, and its massive take-up in the following decade, many organizations have implemented e-mail and web-based suggestion schemes. In the former, an e-mail address is set aside for the collection of ideas and employees are encouraged to use it. In the case of web-based systems, employees complete an on-line form to submit their ideas to a database. In knowledge-based companies, where most employees have computers on their desks, such systems make it easy to submit ideas.

Most suggestion schemes have more clearly thought-out front ends than back ends. Indeed, the simplest, ad hoc systems essentially have no back end. Like the suggestion box of old, an employee – often a manager – regularly looks at every submitted idea and makes a decision as to whether to escalate each idea – in other words, send it for further review such as the development of a business case – or to dispose it of. More sophisticated systems boast a range of tools that allow collaboration on ideas, provide structured review processes, provide voting, and much more. In many cases, such sophisticated

2 idea management

tools are called “*idea management software*”. However, the lack of a means to focus ideas arguably prevents a suggestion scheme from actually being considered an idea management solution.

FATAL FLAW WITH SUGGESTION SCHEMES

In spite of their popularity, suggestion schemes in medium to large organizations suffer from a serious flaw: they typically fail after 12–18 months, in this author’s experience. The cause of failure is almost inevitably the lack of focus of suggestion schemes, which leads to several undesirable consequences:

1. If the suggestion scheme is well promoted in the organization, it leads to a high number of submitted ideas. A huge influx of such ideas is often too much for a single person or team to manage. As a result, they are unable to process the ideas in reasonable time and provide feedback to the idea submitters. Idea submitters, in turn, get no information about their submissions and assume management is not really interested in their ideas. Hence, they do not continue to submit new ideas.
2. If the system is blind, that is, idea submitters cannot view each other’s ideas, there tend to be a very large number of duplicate and very similar ideas. This not only slows down the processing of ideas, but poses problems to the suggestion scheme’s manager, specifically as to who to acknowledge as the idea initiator and how to prevent hard feelings among others who submitted similar ideas and who are not recognized as the initiator.
3. Many submitted ideas are not relevant to business needs. Hence they need to be rejected. This results in a high failure rate, which is demotivating to employees and tends to discourage continued participation in the scheme.

To illustrate the last point, the author is familiar with a multinational manufacturing and engineering firm, which launched a suggestion scheme in its Chinese head office. To ensure the open communication and fast flow of ideas, the team in charge of the scheme was required to review every idea as soon as it came in

and give feedback to the idea owners within a week. However, most of the ideas were not relevant to business needs and had to be rejected. While most suggestion schemes fail within 18 months, this one lasted far less than a year. In retrospect, it is not difficult to understand why. Employees submitted ideas that they felt good about. Within a week, they received a critical report rejecting their ideas. Essentially, the company was communicating that it did not like the employees’ ideas. This became particularly apparent as employees discussed results with each other. The problem was exacerbated by Chinese culture. Employees felt they had lost face by being rejected by management! As a result, an expensive suggestion scheme not only resulted in very few viable suggestions but created negative feelings among employees, especially the most creative thinkers.

In 2007 and 2008, several large organizations launched public, web-based suggestion schemes in which anyone could register and submit ideas. Although these have succeeded as publicity tools and communication tools – facilitating customer feedback – they have not demonstrated impressive results as innovation tools. A quick look at the most popular of these schemes will reveal that thousands of ideas, including numerous duplicates, have been submitted and that at most a few tens have been reported as being considered for implementation. Moreover, if one assumes that each idea will take an employee an average of 10 minutes to review, each 1000 ideas will require 166.7 man hours to process. That is not an efficient back end.

Fortunately, there are better and more efficient methods of capturing focused business ideas from large groups of people.

CREATIVE PROBLEM SOLVING (CPS)

Creativity experts have long known that great ideas very rarely explode out of nowhere. Rather, they are developed in the process of collaboratively seeking a solution to a problem. Although creative problem solving has been around since humans attained the ability for abstract thinking, the process was probably first defined by Alex Osborn, the inventor of BRAINSTORMING, and a cofounder of Barton, Durstine & Osborn,

an advertising agency that is now a part of BBDO Worldwide. He published his approach to brainstorming in 1948 in his book *Your Creative Power*. Here he laid out the notion of a defined problem and an open, uninhibited period of idea generation (Osborn, 1948). Over the next decade, Mr. Osborn together with Dr. Sidney Parnes developed the brainstorming approach into a more structured process they called *creative problem solving* or *CPS*. Since then, CPS has been further refined and developed, largely at the International Center for Studies in Creativity at Buffalo State College (Firestien, 1996). However, many variations of the process have been adopted by practitioners of creativity and innovation. For the purposes of this article, we will consider a simple seven step process:

1. identifying a problem, a goal or a need;
2. researching the problem to better understand your actual requirements;
3. formulating a creative challenge;
4. generating ideas in response to the challenge in an open, uninhibited and noncritical environment;
5. evaluating and combining ideas to develop viable solutions;
6. drawing up an action plan for implementing the ideas;
7. implementing the ideas.

Applying CPS to the suggestion scheme results in what idea management experts variously call an *ideas campaign*, an *event* or a *challenge*. We will use the term *ideas campaign* in this article. It is such an effective approach that it forms the basis of most of the established commercial idea management software products available today. Let us look at how an ideas campaign works.

IDEAS CAMPAIGNS

An ideas campaign essentially follows the CPS approach with minor modifications. In particular, the idea generation phase of a CPS event, such as brainstorming, typically lasts a few hours or at most a day or two and includes a relatively small group of participants. In an ideas campaign, in which hundreds or thousands of

people in various locations participate, the idea generation phase typically lasts anywhere from one to four weeks – sometimes even longer. Idea management software backed by a robust, scalable database facilitates participation by such a large number of people.

Of course, an ideas campaign is a single event. However, by running simultaneous and sequential ideas campaigns, an organization will have a sustainable, effective idea management process that focuses innovation on business needs. We look at the advantages of the ideas campaign approach to idea management over suggestion schemes later in the text. First, let us take a look at the elements of an ideas campaign.

Innovation challenge. An ideas campaign starts with an innovative challenge, which is typically a terse, focused question such as “What new products might we develop?” or “What business opportunities might we exploit in China?” As with CPS, this challenge should not be hastily formed. Rather it should be developed through internal questioning and research (VanGundy, 2007). In this author’s experience, too many managers make their challenges overly vague – using only a word or two, for example: “Marketing ideas” – or overly detailed, bringing in market research, analysis, and more. In the former case, participants are unsure of the managers, needs and in the latter case, the excess of details tends to discourage participants as they fear they will submit an unsuitable idea.

Idea generation. Once the ideas campaign is launched with an innovation challenge, participants are invited to submit their ideas. In an ideal idea management system, all submitted ideas are visible to all participants and some form of commenting function permits collaborative idea development. During the idea generation phase, it is important that management be supportive and encourage submission of ideas. Criticism or rejection of ideas at this stage at best discourages creativity in idea submission and at worst discourages participation altogether. As Mr. Osborn found out, while developing brainstorming, criticism during the idea generation phase makes people fear ridicule, personal criticism, and possibly even reprimand. As a result, they will be more cautious – and hence less

4 idea management

creative – in their idea submission or may opt not to submit any ideas at all. From the participants' point of view, if idea submission results in criticism, not submitting ideas is a good way to avoid that criticism.

Evaluation and review. At the end of the idea submission phase, it is time to identify the best ideas. This is done via evaluation of ideas and combining complementary ideas together. There are numerous idea review approaches used in different systems. Some of the more common-place methods are described below.

Evaluation matrix. The evaluation matrix is essentially a peer review process. It compares an idea against a set of criteria. Evaluators indicate on an online form how well they believe the idea meets each criterion. The software then calculates and compiles an overall score and generates a report. Evaluators are typically internal experts with substantial knowledge relevant to the theme of the innovation challenge. Having multiple experts ensures a more balanced review than would be the case if an individual were to evaluate the ideas alone.

Pass/Fail. A simple pass/fail selection is often necessary to hone down a large number of ideas into a small, more manageable number of ideas for more detailed evaluation. A pass/fail selection should be based on one or more criteria to make the selection process as objective as possible.

Voting. Users of the system vote for ideas. The ideas with the most votes are selected for further processing. Although popular, voting is not normally a scientific approach to idea review. Highly innovative ideas are seldom the most popular. Indeed, they often seem the most absurd initially. As a result, they are unlikely to receive many votes. Incrementally innovative ideas, on the other hand, are easier to grasp and less radical. Hence usually they do better in open voting systems. In other words, putting ideas to a vote typically results in less innovative ideas getting high scores and highly innovative ideas getting low scores.

SWOT Analysis. A strength, weakness, opportunities, threats (SWOT) analysis is a

widely used business method for evaluating ideas, particularly product and marketing ideas. As a result, it is also a useful tool in an idea management process that includes generating such ideas.

And beyond. Once ideas pass the initial evaluation tests, they are often developed into business cases, turned into prototypes, subjected to market analysis, and more, before businesses invest in their implementation. This is particularly true where ideas require a substantial investment to launch. However, these more advanced tools are seldom part of an idea management tool or process. Product development and project development are usually considered entirely different disciplines from idea management and, as a result, are overseen by different teams.

ADVANTAGES OF IDEAS CAMPAIGNS OVER SUGGESTION SCHEMES

Idea management by ideas campaign clearly has several advantages over a suggestion scheme.

1. Creative idea generation is focused on actual business needs as identified by managers who are typically decision makers. As a result, ideas are more likely to be relevant and useful. This means there are more suitable ideas and fewer rejected ideas.
2. All ideas focus on solving a particular problem. This facilitates combining ideas to build better ideas and allows for comparative evaluation. In other words, rather than just reviewing one idea for viability, managers can review numerous solutions to identify the best idea or ideas.
3. A creative challenge is far more motivating than a simple request for ideas. Compare sitting in a brainstorming session where the facilitator simply says "Give me your ideas!" against a session where the facilitator asks "What creative uses might you make of a brick?" It would clearly be easier to generate ideas for the latter! The same is true for idea management.

Indeed, the advantages of the ideas campaign approach, over the suggestion scheme, as a

process for generating viable business ideas is so clear that it has become the basis of most idea management systems. Nearly all commercially available idea management software products use a variant on this approach and consultants also use it as the structure of any idea management process they implement. Nevertheless, there are a few firms that still use suggestion schemes, and many organizations wishing to design their own idea management software almost inevitably start with a suggestion scheme. This is typically because the system is designed by software programmers rather than innovation experts.

PUTTING IT ALL TOGETHER

Most sustainable idea management initiatives today are based around running regular ideas campaigns. Often ideas campaigns feed each other. For instance, a manager runs an ideas campaign for new-product ideas. One of the ideas is selected for implementation. As a result further ideas campaigns are run about how to implement the product's features, how to package the new product, how to position the product in the marketplace, and so on.

In addition to ideas campaigns, most idea management processes also provide a means of submitting spontaneous ideas that do not fit in any running ideas campaigns. This is a good means of capturing good ideas that may come to employees as a result of outside stimuli. However, care must be taken not to become reliant on spontaneous ideas as the focus of an idea management program. Otherwise it becomes little more than a suggestion box.

For the most part, idea management programs based on ideas campaigns use commercially available idea management software to facilitate the process.

In addition to software and structure, there are several human components that need to be added to any successful idea management initiative.

FACTORS IN THE SUCCESS OF IDEA MANAGEMENT INITIATIVES

Even with the best software and operational plan, many idea management initiatives fail to meet expectations largely owing to poor levels of participation. In this author's experience there

are two reasons for this. The first is that people simply do not know about the initiative. The second, more commonly, is that people claim they have no time to participate. Indeed, at least one study has identified "lack of time" as the number one hurdle to organizational innovation (Morris, 2005). Yet a moment's thought is sufficient to realize that this makes no sense. Every employee in an organization has at least 35 hours per week of time. Most have many more hours. Hence people are really saying that participating in innovation initiatives is not of sufficient importance for them to devote some of their time, and that it is of very little priority. Moreover, if most people in an organization feel that innovation is not a priority, there is little likelihood that idea management or any other innovation activity will achieve its aims.

For any idea management project to succeed, it is important to make innovation a high-level priority in the minds of the employees expected to participate. This achieved, management can work toward continually improving the results of their ideas campaigns. In this author's experience, management buy-in, a good promotional plan, a rewards scheme, and a willingness to take on the risk of implementing creative ideas are the key ingredients to a successful idea management initiative.

Management buy-in. If top management is not behind an idea management initiative, they cannot expect subordinates to bother with it either. If employees see that management is not demonstrably interested in participating in idea management, they will quickly learn that there is no personal benefit in participating themselves. On the other hand, if managers are actively involved in idea management, submitting ideas themselves, and personally thanking submitters of ideas for their contributions, employees will see that management is serious about innovation and that it is a corporate priority.

For managers wanting to introduce idea management, this is critical. They must not only look at the software and resource requirements. They must be prepared to invest their own time and energy in it. Innovation and idea management must be made a top priority.

Promotional plan. If employees do not know

about their firm's idea management activities, they can hardly participate. If they do not understand the importance of the idea management initiative, they are unlikely to prioritize participation. Hence, any idea management process planning needs to include a promotional plan designed to communicate the details of the process, why the idea management initiative has been launched, why everyone should participate, the benefits to the organization, and the benefits to the participants themselves.

The promotional plan should include an explanation of the process, information about the rewards system (more below), and a description of how to participate, including a URL of the idea management software, log-in procedures, and anything else people will need to know to use the system.

Beyond promoting the idea management initiative to employees, management should also promote it to clients, stakeholders, business partners, and possibly even the general public. This helps clarify in the employees' minds the importance of the innovation initiative and tells the outside world that the firm is very serious about innovation.

Rewards scheme. Rewards, for submitting ideas to an idea management system, are a good way to motivate people to participate. However, a poorly designed rewards scheme can actually discourage people from participating. So any rewards scheme needs to be carefully designed and should follow two basic rules.

Lots of small rewards. It may seem counterintuitive, but expensive rewards such as large cash prizes or highly valuable gifts can actually destroy an idea management process. When rewards are too big, people tend to begin acting selfishly. Managers steal subordinates' ideas, people do not collaborate – which minimizes the development of ideas – and people act solely to win rewards rather than to innovate on behalf of the company.

Small rewards, on the other hand, are not valuable enough to encourage selfish action. Rather, the rewards are appreciated by employees as acknowledgement by management of each person's participation. Moreover, people can be competitive with small rewards without

causing excessive bad feeling from those who have received fewer rewards.

In the early stages of an idea management implementation, a small reward such as points that can be exchanged for gifts, a chocolate, or a piece of fruit for every idea is an excellent means of encouraging employees to log into the idea management system and submit ideas. Once employees have done this, and provided the software is sufficiently intuitive to use, employees will quickly become used to using it and participating in the initiative.

Reward for quantity or creativity – but not for quality. A frequently made mistake in rewards schemes is to offer rewards for “the best ideas.” However, research has shown that this actually results in reduced creativity and fewer ideas (Sawyer, 2007)! But with a moment's thought the reason for this is clear. When participants are told to produce good ideas or compete to submit the best idea, they aim to please management. As a result, they submit ideas they believe managers will like rather than risk submitting an unusual idea that management might not like. Ideas that management are perceived to like will be ideas that are similar to ideas and actions management has taken in the past. In other words, unusual and hence creative ideas are rejected in favor of ideas that are at best incremental improvements on existing concepts and hence not very creative.

Rewards for the most creative ideas or the most outrageous ideas, on the other hand, can be an effective means of encouraging creative thinking. This indicates to participants that they are invited to open their minds and think freely. The result tends to be fewer ideas than in ideas campaigns with quantity-based rewards or no rewards, but those ideas do demonstrate a higher level of creativity (Sawyer, 2007). Thus such rewards can be an effective strategy once the idea management process is operational and familiar to employees.

Group rewards versus individual rewards. One last note – in general, rewarding teams and groups is more effective than rewarding individuals, particularly if the rewards are larger. This has consistently been demonstrated in research and is intuitive. The

advantage to idea management, like other group idea generation methodologies, is that people can collaborate together to build bigger ideas than would be possible for any team member as an individual to achieve. However, if rewards go to individuals, team members have an incentive not to collaborate as doing so might result in a colleague being rewarded for the idea originator's solution. On the other hand, if an entire team, group, or business unit is rewarded, all members have an incentive to collaborate and cooperate. This results in better developed, more innovative ideas.

Willingness to take on risk. No matter how well organized an idea management initiative is, it will not be an effective innovation tool if management does not implement the ideas it generates. As obvious as this notion is, it is surprisingly frequently not followed.

Potentially innovative ideas are inherently risky. They are new, untested, and deviate from the norm. The more innovative an idea is, the greater is the risk of failure. Conservative managers are often unwilling to take on such risk and ironically fail to implement the most potentially innovative ideas their people develop.

As a result, any idea management initiative should be accompanied by a risk management structure designed to accommodate innovative ideas. This might include a specified budget

for high-risk ideas as well as a strategy for risk management. Such a strategy should include milestones against which an idea's implementation may be measured. If the idea fails to meet or exceed milestones, it should be reviewed. If the problems cannot be solved, the idea must be dropped, and another innovative idea implemented. Such an approach reduces risk and yet ensures a steady stream of innovative ideas are being tested and implemented. And that, more than anything, demonstrates the successful implementation of an idea management system.

open innovation

Joel West

INTRODUCTION

Control of research and development has been long assumed to be crucial to the success of large firms in technology-intensive industries. The rise of the great vertically integrated chemical, automobile, and electronics companies in the early twentieth century – and IBM in the postwar era – have been held out as examples of how industrial R&D enabled firms to offer new products and capture new markets, as portrayed by the business histories of Alfred D. Chandler, Jr. studying large industrial firms such as BASF, General Motors, and Unilever. In the United States, the industrial research of IBM and AT&T's Bell Labs was exemplars of corporate R&D that spawned firm and societal success.

However, such exemplars had important limitations. Henry Chesbrough studied the successful and unsuccessful efforts of Xerox to commercialize innovations from its famed Palo Alto Research Laboratory (Xerox PARC), concluding that it was essential for firms to align their innovation efforts to business models (Chesbrough and Rosenbloom, 2002).

In his book *Open Innovation*, Chesbrough (2003a) concluded that the traditional vertically integrated model was failing as firms increasingly paid a penalty for failing to commercialize their innovations, because of greater customer demands and market pressures. Meanwhile, knowledge is increasingly dispersed and mobile, as researchers who helped develop a technology can commercialize it by moving to a new employer or start their own company.

Chesbrough's conception of open innovation has important antecedents in both research and practice. Prior research includes the work on profiting from innovation by Teece (1986) and Eric von Hippel's prolific work on user innovation. Extant managerial practice includes product modularity, component-based innovation, and systems integration – particularly in electronics-based industries – as well as patent licensing business models from companies like

Dolby Labs, Qualcomm, and dozens of start-up biotech companies.

Nonetheless, Chesbrough (2003a) has inspired a new subtopic within innovation studies, as researchers have studied a broad range of efforts by firms to source and commercialize innovations outside their firms' boundaries.

DEFINITION

Chesbrough (2003a: xxiv) introduced open innovation as “a paradigm that assumes that firms can and should use external ideas as well as internal ideas, and internal and external paths to market, as the firms look to advance their technology.” In a subsequent book, Chesbrough offered this expanded definition:

Open innovation is the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the markets for external use of innovation, respectively. [This paradigm] assumes that firms can and should use external ideas as well as internal ideas, and internal and external paths to market, as they look to advance their technology (Chesbrough, 2006: 1).

As an editor of the 2006 book, the author knows that Chesbrough intentionally chose “purposive” over “purposeful,” although this choice forces people to go to their online dictionary. Something more concise using simpler language was required for the author's own teaching, presentations and blogging, so he developed these two alternatives:

Open innovation means treating innovation like anything else — something that can be bought and sold on the open market, not just produced and used within the boundaries of the firm.

Firms that embrace open innovation employ markets rather than hierarchies to obtain and commercialize innovations.

Both of these latter definitions focus on the transaction cost economics (TCE) critique that was implicit in Chesbrough's original definitions. TCE argues that managerial hierarchies (in this case, vertical integration) are only preferable when market transactions would be too

2 open innovation

expensive due to the costs of search, bargaining, contracting, or enforcement.

These latter definitions also suggest that open innovation is possible only with efficient and effective markets for innovation that provide for search, valuation, and bargaining, as well as legal institutions that enable contracting and enforcement. This is consistent with Chesbrough's (2003a) original observations about the importance of intellectual property (IP) and markets for buying and selling such IP.

Even with such markets, transactions will only occur if there is a sufficient population of willing buyers and sellers participating in the market, since unrealistically low (or high) prices will deter participants from using open innovation in preference to vertical integration. As Chesbrough (2003a) notes, accurate pricing is made more difficult when a firm cannot precisely value its IP, particularly when an innovation requires the firm to develop a new business model.

That is not to say that open innovation is only possible through markets: Chesbrough repeatedly encourages firms to accept (but not create) free spillovers of innovation from external sources. Chesbrough (2003b) identifies a key category of external sources which he terms "innovation benefactors," to include those (such as the US National Science Foundation, National Institutes of Health, or disease-specific nonprofit foundations) that provide funding for innovation. At one point university research (whether internally funded or government funded) served as sources of free spillovers, but after the 1980 Bayh-Dole Act, US universities have moved to aggressively patent and monetize their innovations. Under this regime, opportunities to exploit large-scale free spillovers of government-funded university research – such as those that created the Internet – may have become a thing of the past.

Researchers have identified specific aspects within the open innovation process. All draw a distinction between external commercialization of internal innovations and internal commercialization of external innovations. (Firms practicing open innovation are assumed to balance those practices with vertically integrated commercialization where that is more appropriate.)

Chesbrough's (2003a) initial definition focused on firms finding markets for their internal innovations, while identifying and utilizing external sources of innovation. For the large firm, the key determinant for a firm commercializing its own (or others') innovation was the alignment of the innovation to new or existing business models. For small firms, the need to go outside for commercialization is consistent with the Teece's (1986) conclusion that to profit from their innovations, innovators who lack complementary assets necessary for commercialization must contract for the missing parts of the value proposition.

To Chesbrough's focus on commercializing internal and external innovations, West and Gallagher (2006) identified a third issue: motivating a supply of external innovations. While the IP market view assumes external innovations can be purchased, their studies identified the case where innovations are obtained from external sources through nonpecuniary incentives such as reputation enhancement.

Building on the internal/external distinction – which they term "inside-out" and "outside-in" – Enkel, Gassmann, and Chesbrough (2009) extended it to include a third mode for innovation creation and commercialization: the "coupled process" of cocreation with complementors and other parties. This is consistent with (as will be discussed later) community-level and industry-level open innovation processes, as well as overlapping user innovation and cumulative innovation research.

Researchers have used differing (often implicit) definitions of what constitutes an "innovation": in the original exemplar of Chesbrough (2003a), innovations bought and sold by firms included basic research, patents, and manufactured components. As in user innovation, the focus often emphasizes the openness of the process rather than the innovativeness of the outcome, thus including as "innovation" incremental improvements on well-developed technologies.

Chesbrough's use of "open innovation" is not without its controversy. "Open" refers to the permeability of an organization to its external environment, as emphasized in open systems theory by organizational theorists such as Daniel Katz, Robert Kahn, and W. Richard Scott.

However, the emphasis in open innovation on monetizing knowledge flows across organizations boundaries puts it at odds with other theories (and their associated policies and normative prescriptions) that assume that openness means knowledge sharing and nonmonetized knowledge flows. Another controversy arose when some researchers questioned the novelty of the open innovation process – although Chesbrough and others freely acknowledge the importance of prior research and practices.

RELATED THEORIES

Open innovation is not the only stream of research that considers the production of innovation across (or outside) organizational boundaries – in contrast to the Chandlerian vertically integrated ideal – nor is it the only one to consider separately the creating and diffusing (including commercialization) of innovations. The two most closely related streams are user innovation and cumulative innovation, which share a common interorganizational perspective, but differ in their assumptions, findings, and implications for policy and practice (West, 2009).

As created by Eric von Hippel, research on user innovation emphasizes the unique (and “sticky”) knowledge of unmet needs held by informed users (see von Hippel, 2005 for a review and summary). This knowledge gets applied and diffused in a variety of ways. One approach is for firms to identify and enlist lead users to suggest new avenues for firms in their product development efforts (see LEAD USERS). A complementary stream of research describes mechanisms such as “user toolkits” that allow users to prototype and even implement solutions to their own problems. Other research has considered communities of users sharing solutions with each other, and users directly commercializing their own ideas by becoming user entrepreneurs.

Meanwhile, research on cumulative innovation (or “collective invention”) tends to focus on radical innovations that are technologically immature, but are successively refined by competing producers (see West, 2009 for citations). Research on cumulative innovation

embraces a range of assumptions about knowledge sharing, from the intentional collaboration of a communal group of producers to the unintended (and uncontrollable) spillovers between rivals locked in a Darwinian struggle for success.

Some of these researchers have used the term *open innovation* to refer to these more collaborative, less profit-oriented innovation processes. More recently, von Hippel (2005) consciously used the phrase “open and distributed innovation” to refer to this sort of collaborative process, as distinct from the concept of Chesbrough and his successors.

A major difference between open innovation and the other two streams is their respective assumptions (and recommendations) about intellectual property rights. Open innovation usually assumes that markets for innovation are enabled by strong appropriability through strong IPRs (intellectual property rights), particularly patents (West, 2006). Further, the other two streams warn of the consequences of excessively strong IPRs in hindering collaboration, user innovation and spillovers, and in some cases explicitly recommend relatively weak IPRs (West, 2009).

While they have distinct emphases, these three streams do have common areas of interest, most notably in open source software (see OPEN SOURCE). Software by its nature is a nonrivalrous information good that is easily shared (or transmitted), while large software systems have the malleability and modularity that permit distributed production of individual components. The rise of free software (and later open source software) during the 1990s and 2000s enabled distributed use and production of entire systems. There is the open question (cf. West and Lakhani, 2008) as to whether a typical open source project generates “innovation” as normally defined in the literature – particularly for projects like Linux that are freely distributed imitations of existing technologies – but the latter are included in the cost reduction definition of “radical innovation” used by O'Connor and her colleagues (see RADICAL INNOVATION).

The largest body of such research on open source is present in the user innovation stream (see von Hippel, 2005 for a summary of relevant work). Many of the most successful early

free or open source software projects originated with software developers “scratching an itch,” mapping directly onto the user innovation paradigm of users addressing their own unmet needs. Meanwhile, users worked in peer and hierarchical communities to correct defects on the shared software product and provided mutual tech support. They also added new capabilities by using user toolkits that allowed creation of plug-in modules and other software components.

At the same time, open source software provided an economical and increasingly important source of external innovations for IT firms during this same period. West and Gallagher (2006) identified four different ways that firms were employing open innovation in their open source strategies. The first was to spin out innovations from the firm – not as Chesbrough (2003a) suggests into new firms, but into new nonprofit open source communities. The second is to use open source as a form of pooled R&D, as when major computer vendors collaborate to produce Linux for use with their respective computers. Finally, they identified two forms of software hybrids combining proprietary and open source components: those where the external open source technology was the core (while the firm sold complements), and those where open source complements increased the value of a proprietary core.

PHENOMENA OF INTEREST

The open innovation paradigm was conceived based on Chesbrough’s (2003a) observations of managerial practice. This included both the paradoxes faced by Xerox’s Silicon Valley researchers in commercializing IT breakthroughs within a photocopier company, and IBM’s wrenching transformation during the 1990s away from vertical integration toward a more agnostic attitude toward sourcing and commercializing innovations.

Both in Chesbrough’s telling and subsequent research, the open innovation concept is often associated with information technology or other technology-based industries (Chesbrough and Crowther, 2006). However, the recent research of open innovation has had limited impact on

Silicon Valley, perhaps because the key practices were already quite common here. Building on product modularity, Silicon Valley firms have long since built products such as PCs or network equipment by purchasing components (e.g., microprocessors and random access memories), enabling open innovation business models in which supplier firms monetize their innovations by selling standardized components to systems integrators (West, 2006) (see PRODUCT MODULARITY). (Figure 1).

Meanwhile, the sorts of spin-offs (and acquisitions) identified by Chesbrough and Rosenbloom (2002) to commercialize technology had become quite common in this high tech region by the time that *Open Innovation* (Chesbrough, 2003a) was published. Similarly, new biotech start-ups have for decades licensed internal innovations to large pharmaceutical firms, solving the classic problems identified by Teece (1986) that small start-ups face in profiting from technological innovation because they lack the necessary distribution, manufacturing, or support.

There is anecdotal evidence that open innovation is of greater interest – or at least has greater potential for business transformation – in more mature industries where Chandlerian integration is the norm. Chesbrough’s (2003a) original study of open innovation highlighted Procter & Gamble’s open innovation practices, and as a direct consequence several other consumer products companies have also sought to develop open innovation practices. Some have suggested that open innovation could become the new model for the once vertically integrated automotive industry, as twenty-first century electric car start-ups such as Fisker and Tesla concentrate on engine and integration expertise (emulating the IT model) while buying or outsourcing other activities in the value-creation process.

The diffusion of the concept to established industries has been fueled by the innovation infrastructure. External sourcing of innovation through intermediate markets had been documented prior to the publication of *Open Innovation* (see Chesbrough and Crowther, 2006 for citations). Since that time, Chesbrough has worked directly with the Industrial Research Institute to promote open innovation. The concept was also highlighted by professional organizations such as the Product Development

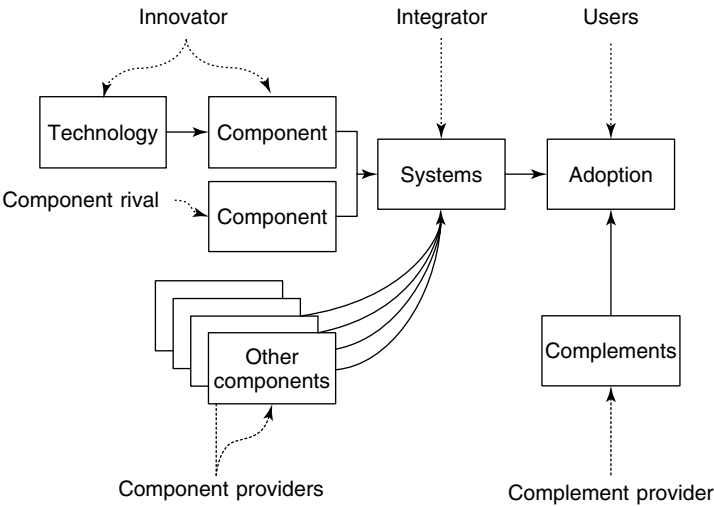

Figure 1 Open innovation for IT products, based on components and systems integration (adapted from West 2006).

& Management Association with consultants and workshops springing up to promote best practice and offer turnkey solutions.

If open innovation is gradually spreading beyond technology industries, it still seems (to use the terminology of Enkel, Gassmann and Chesbrough, 2009) to be mainly focused on the “outside-in” rather than “inside-in” (cf. Chesbrough and Crowther, 2006). This emphasis dominates the popular press, research and business practice, and is likely because of the limited number of firms generating significant quantities of unmonetized IP.

However, the “outside-in” also appears to have an inherent attraction for CEOs seeking to eliminate head count and reduce R&D budgets. For example, in 2008 Hewlett-Packard – the oldest and largest Silicon Valley tech company – renamed its “University Relations” office as “Open Innovation,” to focus on developing and sourcing external technologies from universities and small firms in the face of ongoing layoffs in its research labs. This inflow of external innovation also applies to large companies seeking to continue innovation long after declining margins cause deep cuts in R&D, as evidenced in the embrace of open innovation by former telecommunications monopoly carriers such as BT and Deutsche Telekom.

Researchers have also been studying the increasingly clever practice of stimulating,

identifying, and procuring external innovations. These range from corporate innovation grants provided by HP in the range of \$25 000–100 000 to the \$200 cash grants given by Threadless for winning crowd-sourced T-shirt designs. In few cases, contests have awarded much larger prizes, such as the \$1 million paid in 2009 by Netflix for improving movie recommendations, and the multimillion dollar prizes for space exploration from the X Prize Foundation and NASA’s Centennial Challenge. (Like open source, crowd-sourcing is an area where open innovation and user innovation provide distinct but overlapping perspectives and predictions.)

If there is increased interest and research on commercializing internal innovations, the emphasis is most likely less on the R&D-intensive multinationals (like Xerox or IBM) and more on small start-ups trying to solve the Teece (1986) commercialization dilemma. Open innovation practices would be applicable to incubators and programs such as the US Small Business Innovation Research grants, which seek to help fledgling entities unlock value from their innovations, whether by bringing products to market or licensing their technologies or components to other firms.

LEVELS OF ANALYSIS

In principle, open innovation is a form of

economic organization that has implications for industries, sectors, and national economies. However, both as conceived and originally researched, the focus has almost entirely been about dyadic exchange (West, Vanhaverbeke, and Chesbrough, 2006). Often, the emphasis is on the firm and its make versus buy decision to procure external innovations from the market (Laursen and Salter, 2006), or the analogous considerations on offering internal innovations to the market. In a transactional perspective, studies consider the search, evaluation, contracting and enforcement activities of in- or out-licensing technologies (e.g., Chesbrough and Crowther, 2006).

While this exchange normally takes place between two firms, even this dyadic perspective can be expanded in several ways. The supplier of external innovations to a firm may not simply be another company, it may be a nonprofit entity such as a university or government, R&D joint venture, or an individual (Chesbrough, 2003b; West and Gallagher, 2006). Increasingly, both open innovation and user innovation researchers are interested in these alternative suppliers of innovation to firms (West and Lakhani, 2008). These entities (e.g., university technology licensing offices) may have the same profit-maximizing motives as other innovation suppliers, but often the nonprofit actors are driven by nonpecuniary motives such as reputation.

However, the adoption or practice of open innovation can be studied across many other levels of analysis beyond the firm (Table 1). The dyadic perspective has been extended horizontally and vertically to compare and contrast the innovation flows across a business ecosystem. Open innovation may be an integral part of a value network of relationships between firms in a given industry or sector (Vanhaverbeke, 2006). Alternately, horizontal contrasts can be drawn between the choices of similarly situated firms in a given market (Christensen *et al.*, 2005). These two perspectives can be combined to contrast the performance of rival value networks practicing varying levels of vertical integration versus open innovation, but to the author's knowledge this has not yet been done.

Open innovation also has implications for entire industries, sectors, or national economies.

Industries that develop a supply of (or demand for) external innovations may de-integrate around interlocking relationships of innovation buyers and innovation merchants. The supply of such innovations may be fueled by nonprofit or government innovation benefactors, such as the Wellcome Trust or the National Renewable Energy Laboratory. Meanwhile, national governments (particularly in the European Union) have taken an interest in policies that promote or discourage open innovation

EMPIRICAL STUDIES

As with any new theoretical framework or paradigm, case studies were prominent in the open innovation research immediately following Chesbrough (2003a); space limitations prevent mentioning more than a handful. Chesbrough himself provide key case studies involving IBM, Intel, Procter & Gamble, and Xerox (Chesbrough (2003a); Chesbrough and Rosenbloom, 2002). West and Gallagher (2006) considered firm open innovation strategies for 10 open source software projects – involving both firm- and individual-level contributions – as well as individuals contributing modifications (“mods”) to role-play video games. Christensen *et al.* (2005) contrasted the outside-in, inside-out and vertically integrated innovation strategies of consumer electronics manufacturers in response to the shock of a radical innovation, the Class D digital amplifier.

Another research design commonly used early in a new research paradigm is an exploratory qualitative research. In one such study, Chesbrough and Crowther (2006) identified 40 early adopters of open innovation outside “high tech” (i.e., IT or pharmaceutical industries), and then conducted semistructured interviews with 12. Their study suggests different motivations and strategies used by firms for identifying, procuring and integrating external source innovations. They also found that firms seeking external innovations sought new applications of proven technologies to their industries rather than risking investments in unproven “new to the world” technologies.

Broader generalizability requires large-scaled studies of a representative population of firms or other innovation participations. One of the

Table 1 Levels of analysis in open innovation research.

| <i>Level of Analysis</i> | <i>Definition of Adoption</i> | <i>Possible Phenomena</i> |
|--------------------------|--|--|
| Individual | Firms source innovations from nonemployees | Crowd-sourcing Video game “mods” |
| Community | Firms leverage a process of external innovation by communities | Open source software Open science |
| Organization | Firms obtain external innovations from other organizations | Component business models Patent licensing Sponsored university research |
| Value network | Firms cooperate across a value network to create and commercialize innovations | System integration Ecosystem management |
| Industry/sector | Open innovation is commonplace by firms across an entire industry or sector | Personal computers Biotechnology |
| National institutions | Government agencies adopt policies supporting open innovation | Patent reform National laboratories |

first such tests of open innovation came with Laursen and Salter (2006), who used responses from 2707 firms in the UK Innovation Survey to establish a curvilinear relationship between the level of innovation search and innovation performance. Subsequent researchers used national innovation surveys in other European countries including Belgium, Netherlands, Germany, and Italy. Such surveys provide systematic evidence of open innovation across a broad range of national contexts, but the nature of the existing survey instruments limits the inferences regarding causal relationships.

FUTURE DIRECTIONS

By its nature, the research identifying open innovation both encourages broader use of open innovation and changes how it is practiced. In particular, new approaches and mechanisms for open innovation are providing new phenomena for study.

However, there remains a wide range of industries and contexts to be studied. This includes low-tech industries, services, and small and medium enterprises. It also includes studies of firms and policies in other national contexts, beyond the existing settings of Europe and North America. Researchers will also find fertile opportunities for research in companies

and industries that are transforming from vertically integrated to open innovation (or balanced innovation) approaches to produce new products and services.

Most research on open innovation has focused on where it occurs, not where it does not. To identify the preconditions of open innovation, researchers might consider predictions from transaction cost economics. Has the Internet reduced search costs so much that open innovation is appropriate in all national contexts? Or does open innovation occur only in those countries where there are properly functioning IP institutions, and with a pool of small innovative companies that feel they are able to bargain fairly with larger firms that have the ability to commercialize?

Longer term, an important area of future research is developing a detailed understanding of how firms internally organize to develop and commercialize using open innovation, both building upon and updating what we know about organizing for innovation under existing models of industrial innovation. We know a lot about cross-functional teams, lightweight and heavyweight project managers, stage-gate and waterfall scheduling models, but we lack a similar understanding of best practice within firms practicing open innovation.

Researchers also have the opportunity to investigate the overlap of open innovation and other theories. For example, there are numerous opportunities to research phenomena (such as crowd-sourcing) at the intersection of user innovation and open innovation. The two streams of research have different assumptions, predictions, and normative and policy recommendations, but appear to offer congruent suggestions for enabling and identifying sources of external innovations.

As with any theory, it is important to define the boundary conditions of open innovation, either as a phenomenon, or as a “new paradigm” (cf. Chesbrough, 2006) for explaining existing phenomena, particularly regarding the role of small companies as suppliers of innovation. While Chesbrough (2003a) emphasized open innovation as a new paradigm for large firm innovation, does open innovation have something to say to small companies, who were unlikely to fully integrate even before Chesbrough’s research? Similarly, if a large company (like Cisco or Google) scans for external sources of innovation – but commercializes that by buying its creator – what contribution does the open innovation perspective provide? Is that contribution any greater if (as Chesbrough and Crowther, 2006 suggest) firms buy exclusive rights to a small firm’s technology? And what are the implications of such open innovation strategies – exclusive and nonexclusive – for the creation, entry, and growth of innovative start-up companies?

ACKNOWLEDGEMENTS

My appreciation to Fern Evitt of the University of Auckland for sharing the open innovation literature review from her doctoral dissertation.

bass model

Christophe Van den Bulte

MODEL STRUCTURE

The Bass model is a mathematical model of new-product diffusion (see also DIFFUSION OF INNOVATION). It represents how the numbers of people (or other purchasing units, such as households or firms) that have adopted a new product or technology increase over time. The model represents people as being in one of two possible two states at any time: either they have adopted, or they have not adopted. Once they have adopted, they cannot disadopt.

The model can be represented as a differential equation showing what drives the number of adopters to change over time, or as the solution to that equation showing how the cumulative number of adopters increases over time. In this article, the cumulative number of adopters at time t is denoted as $N(t)$ and its first-order differential as $dN(t)/dt$. Note, the latter captures the number of adoptions taking place in the very short time interval $[t, t + dt]$ divided by the length of that interval. For simplicity, $dN(t)/dt$ is often referred to as simply the *number of adoptions taking place at time t* .

The model has three parameters, typically identified as p , q , and m . Parameter p is typically called the *parameter of innovation* or *external influence*. Parameter q is typically called the *parameter of imitation* or *internal influence*. Parameter m is typically called the *market potential*, *market size*, or *diffusion ceiling*. The reason for these names stems from the behavioral rationale for the model, which is conveyed through its differential equation form.

Differential equation. The differential equation form of the model represents the number of adoptions at time t as follows:

$$\frac{dN(t)}{dt} = \left[p + \frac{qN(t)}{m} \right] [m - N(t)] \quad (1)$$

The second term in brackets on the right-hand side represents how many people still have to adopt at time t , by subtracting the cumulative number of adopters $N(t)$ from the number of

people who will ultimately adopt, m . The first term in brackets represents the rate at which people transition from the nonadopter to the adopter state, that is, the rate at which the number of adopters increases.

The transition rate has two components. The first is p , capturing all time-invariant elements that may induce people to or inhibit them from adopting quickly. These may include the product's price, the level of marketing communication support it receives, the extent to which it is easily available in stores, product characteristics such as superior functionality and low risk profile, as well as many economic, demographic, and cultural characteristics of the population of ultimate adopters. The second component of the transition rate is $qN(t)/m$, that is, the parameter q multiplied by the fraction of the market that has already adopted. This second component captures how the rate at which people adopt is affected by how many have already adopted in the past, which may stem from imitation, word of mouth, social contagion, network effects, or other endogenous feedback mechanisms. This interpretation is why q is often referred to as the *parameter of imitation*.

Some scholars interpreting p as capturing only the effect of mass media and marketing communications refer to p as the *coefficient of external influence* (capturing the effect of outside influences acting on the group of consumers) and to q as the *coefficient of internal influence* (capturing social influence effects operating within the group of consumers). However, research documenting that p varies as a function of adopter characteristics (e.g., national culture) suggests that these interpretations and labels do not capture the entire range of factors captured by p .

Diffusion as a function of time. Whereas the differential equation clearly conveys the behavioral rationale of the model, it does not provide a convenient expression directly showing how the number of adopters increases over time. The latter can be obtained by solving the equation as a function of time only. Assuming that $t = 0$ is the time of launch such that $N(0) = 0$, the solution is

$$N(t) = m \frac{[1 - e^{-(p+q)t}]}{[1 + (q/p)e^{-(p+q)t}]} \quad (2)$$

2 bass model

Mathematical analysis of this equation provides additional insight into how the model parameters affect the diffusion curve, with time on the horizontal axis and the cumulative number on the vertical axis. First, m simply elongates or shrinks the entire curve vertically, without affecting its shape, and so “scales” the diffusion ceiling or market size. Second, the sum of p and q elongates or shrinks the entire curve horizontally, without affecting its shape, and so “scales time.” Finally, the ratio of q and p determines the shape of the curve. Whenever q is larger than p , the curve will have an S-shape, and the larger the (q/p) ratio is, the more pronounced the S-shape will be. The time of inflection when the S-curve goes from being convex to being concave, which corresponds to the time at which the largest number of people are adopting, is given by $t^* = [\ln(q/p)]/[p + q] > 0$ when $q > p$. When q is equal to or smaller than p , in contrast, the curve of cumulative adoption is concave without any inflection point, and the number of adoptions taking place at any point in time is the highest at $t = 0$ and then decreases over time.

Figures 1 and 2 illustrate how q/p drive the shape of the curve. Figure 1 shows that, when q is larger than p , the cumulative number of adopters $N(t)$ follows the type of S-curve often observed for really new product categories (see TECHNOLOGY S-CURVE). When q is smaller than p , the cumulative number of adopters follows an inverse J-curve often observed for less risky innovations. Note, the curves in Figure 1 are rescaled

to be cumulative penetration curves, that is, they show $N(t)$ divided by m . Figure 2 shows the corresponding patterns for $dN(t)/dt$, again divided by m , which can be interpreted as the proportion of new adoptions occurring at time t . Note that an S-curve for the cumulative proportion of adopters (Figure 1) corresponds to the familiar bell-shaped curve for the noncumulative proportion of adopters (Figure 2).

Typical values for parameters p and q . The model has been applied mostly to consumer durables, high-technology products, and pharmaceuticals. For such products exhibiting considerable price or risk barriers, the typical p is about 0.01–0.03 and the typical q is about 0.30–0.40, both measured on an annual scale (Sultan, Farley, and Lehmann, 1990; Van den Bulte and Stremersch, 2004). That q is markedly higher than p is consistent with the distinct S-shape in the diffusion curve of many such products. For consumer packaged goods and other low-risk items such as music CDs or movies with well-known performers, p is often higher (e.g., 0.10 on a monthly scale) and q often is zero. Note, the averages just reported are based mostly on data from the United States, and there is evidence that in emerging economies, values of p tend to be lower and those of q tend to be higher than those just mentioned (Talukdar, Sudhir, and Ainslie, 2002; Van den Bulte and Stremersch, 2004).

Figure 1 The Bass model fits the classic S-shaped cumulative diffusion curves.

Figure 2 The Bass model fits the classic bell-shaped diffusion curves.

INTERPRETATION

Meaning of the parameters. The three parameters not only capture the overall shape of the diffusion process but also have an appealing behavioral interpretation: m represents the market size, q captures word of mouth and other types of social contagion, and p captures all time-invariant influences associated with speedy diffusion. Since the two rate parameters p and q allow two distinct types of influence to operate, the Bass model is also referred to as the *mixed-influence model of diffusion* (Mahajan and Peterson, 1985).

Note that, with this interpretation, the model makes several assumptions. First, the market size m does not change over time. Second, any marketing-mix influences that vary over time are ignored. Third, all people who have already adopted are allowed to influence all people who have yet to adopt, which implies either that everyone interacts with everyone else or that contacts in the population are totally random. Fourth, repeat purchases, multiunit purchases, and disadoption all fall outside the purview of the model. These restrictive assumptions can be relaxed, but at the cost of greater complexity (Mahajan, Muller, and Bass, 1993).

There is disagreement, not to say confusion, about a fifth assumption: does the model assume a homogeneous population or does it allow for different types of customers to exist? This issue

is of fundamental importance because it relates to the presence or absence of customer segments, and is discussed in the next two sections.

Innovation versus imitation. It is tempting to think about the model as representing a diffusion process not only with two distinct influences at work but also with two distinct customer groups or segments: “innovators” unaffected by social influence and “imitators” affected by social influence. Considerable confusion has arisen on this issue.

The model derivation presented above recognizes no differences among potential adopters; that is, though the model recognizes that different people will adopt at different times, the derivation assumes a homogenous market where everyone is equally exposed and sensitive to both independent and social influences. It is clear from Equation (1) that the only people adopting without being exposed to any social contagion are those adopting at $t=0$. The fraction of people adopting at that time is $p \cdot dt$, which is extremely small since the model is technically a continuous-time model where dt is extremely small. So, even though p can validly be interpreted as a coefficient of innovation, it is not the fraction of people adopting independently. The latter is infinitesimally small according to the model’s mathematical structure. If one starts with the assumption that two distinct groups of customers exist, one

4 bass model

adopting with transition rate p and the other with transition rate $qN(t)/m$, one obtains a different mathematical model (Van den Bulte and Joshi, 2007).

So, one cannot interpret the Bass model as a two-segment model. However, it is possible to interpret it as depicting a situation where everyone can, in principle, adopt either independently or through contagion but, at the time of adoption, some people adopt only because of independent forces captured by p and others adopt only because of social influence captured by $qN(t)/m$ (Daley, 1967; Taga and Isii, 1959). This alternative scenario, where no ex ante segments exist but where some adoptions happen independently and others happen only because of social influence—such that adoptions can be said to be either independent or imitative ex post (once they have occurred)—actually is consistent with the Bass model. Under this interpretation of the model, the fraction of independent adoptions taking place at time t decreases continually over time (Mahajan, Muller, and Srivastava, 1990). The fraction of all independent adoptions from the time of launch until full diffusion is achieved, say ϕ , equals

$$\phi = \frac{p}{q} \ln \left[1 + \frac{q}{p} \right] \quad (3)$$

Note, this fraction is a function only of the q/p ratio. For independent adoptions to account for only 2.5% of all adoptions, as some people have proposed to make the definition of innovators as people adopting independently, consistent with Rogers' classic definition of innovators as the first 2.5% of people who adopt (Rogers, 2003), the q/p ratio should equal 215. The latter value is well above the typical value (Van den Bulte and Stremersch, 2004), further underscoring the fact that the concepts of "innovators" and "innovative adoptions" have very specific meanings within the Bass model structure that need not correspond to people's intuitions.

Imitation versus heterogeneity. The discussion so far has followed traditional lines, and presented the model as the mathematical representation of a process among homogenous customers exposed to independent and imitative influences. Alternative interpretations of the

mathematical formulas are possible, however. Like many other mathematical models, the Bass model is overdetermined. In other words, different sets of assumptions can lead to exactly the same mathematical expression. Today, researchers recognize that Equation (2) corresponds not only to a diffusion process in a homogenous population driven by time-invariant independent forces and imitation but also to a diffusion process in a heterogeneous population driven by time-varying independent forces without imitation.

One alternative derivation was presented by Bemmaor (1994). He showed that if people adopt according to a shifted Gompertz process and their tendency to adopt early is exponentially distributed, the resulting expression for the expected number of cumulative adopters is identical to Equation (2). Another alternative is based on the logic of adoption thresholds, well established in economics. The most obvious scenario is one where the price for the new product decreases over time (e.g., because of experience curve effects or increasing competition), and people adopt as soon as the price falls below their maximum willingness to pay or reservation price. If prices come down exponentially (which they tend to do) and the cumulative distribution function of the natural logarithm of reservation prices is $1 - N(t)/m$ where $N(t)$ is defined as in Equation (2), but with the log of price at time t substituted for t , then the cumulative adoption curve will be identical to Equation (2). Assuming such a distribution of threshold prices is consistent with the distribution of income in many countries.

Because the Bass model is overdetermined, one cannot be very confident about what it means when the model fits data well. It might be that the standard mixed-influence process is at work, but one cannot make that conclusion confidently unless one has ruled out the other interpretations. For instance, a study investigating how the q/p ratio in particular countries varied systematically with their income distribution and with several dimensions of national culture associated with social influence found support for both the mixed-influence and the income-heterogeneity interpretations of the model (Van den Bulte and Stremersch, 2004). This finding, together with other studies showing that the evidence of

social contagion may vanish once one controls for changes in the marketing mix, suggests that one must be cautious in drawing conclusions on what drives the diffusion process. While it is true that S-shaped diffusion curves and high values of the q parameter in the Bass model are consistent with imitative processes, they may also result from systematic changes in prices and other factors.

ESTIMATION

Because Equations (1) and (2) are not linear in the parameters, one cannot get direct estimates of p , q , or m using ordinary least squares (OLS) regression. However, one can get direct estimates using maximum likelihood estimation or nonlinear least squares regression. The latter is the most popular estimation today. It is quite easy to implement with standard statistical software and can even be done using Excel Solver. More sophisticated techniques exist as well (Mahajan, Muller, and Wind, 2000).

Obviously, a problem occurs when one wants to use the model for prelaunch forecasting and quantify the model parameters before any sales or adoption data is available. To circumvent this problem, one must use other sources of information, such as managerial judgments, inputs from customer surveys, or the parameter estimates from similar products and countries for which more data is available.

Problems are very likely to occur even after launch, especially very early in the diffusion process, when only limited sales or adoption data is available. In some cases, it is simply impossible to get reasonable statistical estimates. In other cases, the estimates one obtains are reasonable but vary either randomly or systematically as one adds more data points to the data set. If one does not have the luxury to wait for more data to come in, one can again resort to managerial judgments, inputs from customer surveys, or parameter estimates from similar products and countries. In addition, one can also try to combine multiple short data series from multiple products or countries and “borrow strength” across them using random effects models (either Bayesian or non-Bayesian).

So, although nonlinear regression is the most commonly used method to estimate the

Bass model, there are situations where other approaches may be required. Estimation issues are discussed at greater length in Mahajan, Muller, and Bass (1993) and Mahajan, Muller, and Wind (2000).

USES

The model can be used to predict future adoptions or first-time purchases. It can also be used to describe and explain patterns of diffusion. When extended with marketing-decision variables such as price or advertising, the model can also be used to provide advice on how the marketing mix should change over time to maximize profits.

Forecasting. Sales forecasting is one of the model's most popular uses (see NEW-PRODUCT FORECASTING). Both experience and research indicate that the model can provide reasonably good short-term forecasts, but that one can typically do better by combining several forecasts obtained through different models or forecasting techniques (Meade and Islam, 1998).

The model also allows one to forecast what the maximum amount of first-time purchases will be and when they will occur. This information can be valuable for planning production capacity. As already mentioned, the time at which the largest number of people are adopting is given by $t^* = [\ln(q/p)]/[p + q]$ when $q > p$. The maximum number of adoptions taking place throughout the entire diffusion process is then $dN(t)/dt$ evaluated at t^* , which equals $[m(p + q)^2]/(4q)$.

Managers and analysts interested in applying the model to predict future sales must be aware of some issues. First, the model is meant to forecast only adoption or initial purchases, not repeat purchases. Second, the simplicity of the model comes at the price of some strong assumptions. Perhaps the most important one for forecasting purposes is that the potential market size is constant over time, and hence not a function of changes in marketing strategy or in macroeconomic conditions. A third issue to be aware of is that the Bass model can accommodate various smooth diffusion trajectories, such as S-shaped diffusion curves consistent with bell-shaped adoption curves, but not the phenomenon of market chasms between

early and late market segments corresponding to a double-humped adoption curve. Of course, the model can be extended to relax those assumptions, but that will typically make the model more complex and hence less practical. So, depending on whether repeat purchases are important within the forecasting window, whether one can assume the potential market size to remain fairly constant, and whether one believes market chasms to be very likely, the Bass model may or may not be quite appropriate.

Describing and explaining patterns of diffusion. Managers and academics sometimes use the model as a means to quantify, through numerical values of the model parameters, the pattern of diffusion for multiple products, multiple industries, or multiple countries. When comparing diffusion paths for several products or markets, looking at raw data series need not always be informative and patterns may become clearer after plotting parameter values in a two-dimensional map or displaying the smooth best-fit curves rather than the jagged raw data series (of course, color coding can further enhance the intelligibility of one's graphs).

The model can also be quite useful when one is interested in explaining variations across products and markets. One can obtain estimates for p , q , and m (or better, m divided by the size of the population of individuals, households, or industrial establishments), and then use standard statistical techniques to see if they are systematically related to market and product characteristics. Elements that have been shown to affect the diffusion path include average income, income heterogeneity, media and distribution infrastructure, legislation and regulation supporting or inhibiting the uptake of the product, and the presence of competing standards (Talukdar, Sudhir, and Ainslie, 2002; Van den Bulte and Stremersch, 2004).

Of course, companies and consultants may want to build industry-specific databases and look for patterns across products most relevant to their own line of business. In the pharmaceutical industry, for example, researchers have investigated to what extent the coefficients of innovation and imitation are related to drug efficacy, the presence of side effects, being aimed at treating a life-threatening medical condition,

being aimed at treating an acute versus chronic medical condition, lack of competition, and the amount of marketing support at launch. Such industry-specific analyses can provide valuable insights to marketing decision makers.

The model has been extended in many ways to account for more complex phenomena than the original model can account for, such as growth in the market potential, influences across competing or complementary products, the presence of supply constraints, and replacement purchases (Mahajan, Muller, and Wind 2000). Two kinds of extensions, accounting for cross-country influences and for marketing-mix influences, can have particularly important implications for how to market new products.

Improving marketing strategies. Comparisons of diffusion processes across industries or countries provide insights not only about the likely drivers of diffusion but also about what type of industry or country is likely to experience a slow or fast diffusion. The latter can be of immediate use to companies and guide decisions on which markets to enter early versus late, or on how much to spend on marketing in each target market (see also LAUNCH STRATEGIES).

Some studies have extended the model to allow the penetration rate or installed base in one country to influence the subsequent diffusion rate not only in the same country but also in other countries (for a review, see Mahajan, Muller, and Wind, 2000). The evidence suggests that such cross-country influences exist, and that they are asymmetric. This, in turn, has been shown to be an important consideration for how multinational companies should launch their new products. Keeping everything else constant, the presence of influential countries supports a "waterfall strategy," where firms enter markets sequentially from leaders to followers rather than a "sprinkler strategy," where firms enter markets simultaneously, because capitalizing on the free cross-country influence from leading markets allows firms to penetrate follower markets more rapidly or with less marketing support. The logic is exactly the same as in viral strategies where firms target opinion leaders, in the hope that their influence will then snowball through the market and convert other customers at no cost to the firm.

The Bass model has also been extended with marketing decision variables, such as price and advertising. Unsurprisingly, empirical research suggests that marketing-mix variables affect the diffusion path. There is little to no consensus, however, on the specific mathematical form in which such decision variables should enter the model: through p only, through p and q equally, or through m (Mahajan, Muller, and Bass, 1993; Mahajan, Muller, and Wind, 2000). Some researchers feel that different marketing variables should enter the model in different ways, for example, advertising through p (which makes sense if one believes that advertising affects how quickly people decide to adopt, without affecting how many people will ultimately adopt) and price through m (which makes sense if one believes that price affects the fraction of the population that can afford the product but does not affect how quickly one adopts given that one will adopt ultimately). Unfortunately, empirical research provides no clear indication that one particular model specification is better than any other. This lack of guidance from empirical research is particularly problematic as different model specifications, with the marketing-mix variable entering one way rather than another, can have very different implications for how firms should change their marketing mix over time. For instance, models in which advertising boosts p tend to favor strategies where one decreases advertising over time. This is intuitively appealing: one first advertises heavily to get the first adopters, and can then cut advertising expenditures as word of mouth becomes a major influence in converting nonadopters into adopters. In contrast, models in which advertising acts as a multiplier on the entire diffusion rate [$p + qN(t)/m$], which is equivalent to amplifying p and q to the same extent, tend to favor strategies where one first increases advertising over time and then decreases it. This too makes sense, as it implies that one advertises the most when the most adoptions take place. So, we have two very different strategies that are both logically defensible, but on different grounds. The sensitivity of model-based recommendations to model assumptions, combined with the lack of empirical evidence on which set of model assumptions is empirically most defensible, severely limits

the practical usefulness of such theoretical work to date.

ORIGINS AND NAMING CONVENTIONS

The model is named after Frank Bass, who introduced the model to the marketing community in an article published in 1969. The model, however, had been presented by several others before, with Taga and Isii (1959) arguably being the first, and with the most famous sources being Mansfield (1961) in economics and Coleman (1964) in sociology. The article by Bass (1969), however, was the first to actually fit the model to data and estimate values for p , q , and m . It also showed that the model could be used for forecasting purposes, rather than for only descriptive purposes. Today, most marketers refer to the model simply as the Bass model. Some sources also refer to it as the mixed-influence model of diffusion (Mahajan and Peterson, 1985).

brainstorming

Jacob Goldenberg and David Mazursky

BRAINSTORMING—A CRITICAL REVIEW

The knowledge underlying the concept of “brainstorming,” the relative ease of its operation and assimilation in organizational contexts, and the social benefits incurred in brainstorming encounters have created a ubiquity of brainstorming group sessions for problem-solving discussions in large organizations (*see also* CREATIVITY; IDEA MANAGEMENT). Advertising agency staff meet for brainstorming sessions to develop creative concepts or new advertising strategies. Engineers meet to find a solution to problems that “arrest R&D progress” and even CEOs initiate encounters with managers from various levels to review and identify new ideas for the advancement of the organization and its components. These sessions are either planned or improvised, and although sometimes guided by a professional facilitator or by one of the group participants, quite often, the sessions are unguided. The high degree of variety in the nature and management of these discussions may have even contributed to the high acclaim received by the genre of brainstorming sessions in popularity polls among methods of group thinking.

The origin of brainstorming is hardly contested. At the Disney Studios, brainstorming was an accepted method to inspire professional creativity by encouraging interaction and teamwork. Osborn (1957) conceptualized the approach, setting down guidelines to create mental storming. There are a number of assumptions underlying Osborne’s approach:

1. *People are naturally creative:* Unfortunately, the ties that bind us to our routines, and the demanding pace of life, inhibit us from flourishing creatively and generating innovative ideas. Confronted with analogies, we are released from our bonds—exposure to an analogy “disrupts” our routine reasoning and opens our mind to associations that lead to the production of original thought.
2. *Synergies:* A group of people thinking together is superior to a single person

thinking on his or her own. Osborne advocated that “individuals operating in a brainstorming group suggest twice as many ideas as individuals working on their own.”

3. *Deferred judgment:* If we eliminate the requirement to pass immediate judgment as ideas are spoken, we can gradually accumulate a pool of high-quality and original ideas which are subsequently filtered. Related to this assumption is the adage “no line of inquiry should be ruled out”.
4. *Quantity leads to quality:* The more we increase the number of ideas, the greater the probability of achieving a more qualitative set of ideas after filtering. As Nobel Prize winner Jonas Pulling said, “The best way to get a good idea is to get a lot of ideas”.

These assumptions (although formalized after the method came into practice) are the foundation on which the brainstorming method evolved in two major stages:

1. *Conceptual brainstorming:* In this first stage, a group of individuals advance ideas in no particular order, and no criteria for judgment of their merits is applied. Every idea is deemed good, and the more diverse the ideas the better. The expression of even wild and seemingly illogical ideas is invited. When participants listen to the ideas of their fellow group members, they are stimulated to create new ideas in new directions. Osborne advocated that fragments of ideas or thoughts are also welcome, as they may produce a good idea in the mind of another participant. Beyond managing the discussion, the aim of the facilitator, in this stage, is to create a pleasant atmosphere of deferred criticism and to encourage diversity of thought. As Doug Floyd noted, “You don’t get harmony when everybody sings the same note”. Concurrently with bouncing ideas to each other, group members also respond to the ideas and suggestions of their fellow members, thus refining ideas, building new perceptions based on other ideas, or connecting a number of ideas together to consolidate a new perception.
2. *Screening:* In this stage, tens (or sometimes hundreds) of ideas are filtered to produce

2 brainstorming

a reduced set, which is subsequently examined and tested for economic feasibility and value. Underlying this stage are judgment and criticism, of the type formerly deferred in the first stage. According to the classical approach to brainstorming, screening should be performed by persons other than group members involved in the generation of the ideas. This ensures that the members of the filtering team are not captives of the perceptions or experiences of the first, conceptual stage. The importance of criticism at this stage is recognized, and its contribution is considered more significant after ideas have been generated during the first stage.

Brainstorming has captured the hearts of organizations, industries, and business concerns, many of which proudly announce their adoption of this practice, although, in practice, strict application of its guidelines has not been universal. Once brainstorming became a conventional practice and it seemed that nothing could be added to the original formula, the academic world began to examine the essential quality of the phenomenon. In the 1980s and 1990s, the method's effectiveness and relevant success factors were the subject of an increasing number of research studies. Examples of questions highlighted in this body of research are the search for the optimal number of group members and the optimal duration of the brainstorming session. The central question was, "What is brainstorming's real contribution compared to results of a nominal group (a group of individuals who think alone, with no contact among members)?"

One of the prominent findings was the absence of a clear advantage of the brainstorming group relative to the results of individuals who worked alone. This finding appeared repeatedly until no doubt was left in the minds of investigators: a brainstorming session does not generate more ideas or greater creativity in comparison to groups of individuals working with no contact among them (Diehl and Stroebe, 1987, 1991). Is this just another case of detachment of academic research producing surprisingly precise, though irrelevant, results from the reality in the field? If this were a case of a big promise that turned into a disappointing fad, we have to face the intriguing fact that this so-called management

fad has struck roots and thrived for almost 30 years. Admittedly, even the most complex and difficult management hits do not typically maintain a leading position in popularity polls for over two decades. Something is obviously going on here. The question is, who is wrong?

Research indicates that most brainstorming groups did not generate more ideas than their control groups in which individuals worked alone with no contact between them. Already appearing in 1958 (the year of Osborne's publication), the first study on this topic, by Tyler, Berry, and Block (Diehl and Stroebe, 1987, 1991) empirically proved that solitary subjects produced almost twice the number of ideas as subjects working in groups. Most of the numerous studies carried out over the years unanimously supported this conclusion and replicated results that stood in direct contrast to Osborne's claim. Groups were shown to be detrimental to individual productivity (Sutton and Hargadon, 1996).

1. The quality of the ideas themselves and their originality were also inferior to the ideas generated by individuals working without any group effect.
2. The optimal number of group members for a brainstorming session was found to be three or four, inconsistent with the conventional perception of a larger group.

These findings, which reveal that group processes have an adverse affect on creativity rather than contributing to their enrichment, created serious doubts regarding brainstorming as an effective process. Explanations suggested by researchers for the lack of success of brainstorming in laboratory experiments range from targeting elements of individual behavior in groups to the impact of brainstorming on individual problem-solving processes (Paulus *et al.*, 1993). The following is a list of some of relevant factors that have been proposed:

- *Production blocking*: In the course of idea generation, one person speaks while the others listen. As, at any single moment in time, only a single person can contribute ideas to the group, the scope of the potential contribution of individual group members

is limited. Moreover, listening to others express their ideas makes it harder for individuals to concentrate and develop ideas of their own. Even if they succeed in concentrating on their own ideas, recall ability is diminished.

- *Free riding:* As is often the case in groups in which individual efforts are combined, brainstorming groups are not immune to free-riding attempts. In a group situation, individuals contribute their ideas to a group pool, and, consequently, are granted recognition on a group level. An opportunity is created for some members to hang onto the coattails of other, more productive members, and bask in the recognition won by group efforts without contributing personally. These free riders, who may possibly function as creative individuals in a different setting, either repeat ideas already expressed or avoid participating in the discussion.
- *Distractions:* The flow of ideas spoken aloud overwhelms individuals straining to concentrate and develop their own innovative thought. Repeated interruptions compel them to withdraw into simpler ideas that are better able to withstand the “external noise.” Thus individuals are diverted to routine thoughts, mostly in an unconscious process. A related factor affecting the generation of ideas adversely in a group situation is the fact that each individual shares “thinking time” between his or her own thoughts and all the thoughts of his or her fellow members expressed aloud. Thus, group production declines relative to the sum of individual contributions in a nominal group.
- *Deferred judgments create a chaotic world:* In a world with no judgment or criteria for assessment, individuals have no way of knowing if they are “on the right path.” Rather than promoting uninhibited thought, the absence of criteria for successful ideas blocks the flow of thought. This creates two phenomena. The first is a type of helplessness and lack of direction that is typical of a soldier who loses his or her bearing on a navigational task. The second is related to the cognitive loss of bearing, whereby random attempts to

generate ideas unfounded on prior reasoning typically produce routine, well-rehearsed thoughts. These familiar ideas are more easily produced than elusive, less-developed notions.

- *Fear of assessment:* Apparently, despite instructions to the participants prior to a brainstorming session, a degree of apprehension of negative social feedback and criticism persists, inhibiting members from expressing all their original ideas.

This last proposed explanation of relatively inferior results by brainstorming seems counterintuitive at first glance. From our experience with brainstorming, the ideas generated are so wild and preposterous that they could not be reflecting a fear of criticism. A more careful examination has shown that the reality is more complex: it seems that participants have no consternation about expressing a wild idea when there is no chance of its practicability. The rules of the brainstorming game allow far-fetched ideas, and the worst that can happen is that an idea will be received as a joke and not taken seriously as an idea for implementation. But, in the case of an original idea that is genuinely directed at the solution of the problem, criticism may be expressed (and most probably, not forgotten), as it threatens the consensus built on the solutions proposed up to that point. This creates a mechanism that filters out the most practical and dauntless of the original ideas, encouraging more banal ideas on the one hand, and wilder, impractical ideas on the other.

Does all the above lead to the conclusion that brainstorming is like a storm in a teacup? This is not necessarily so. Despite the laboratory experiments that invalidate the effectiveness of brainstorming, field results indicate widespread adoption of the method. If indeed such a large number of people cannot be wrong, then the widespread adoption and persistence of brainstorming as an organizational practice requires an attempt to reconcile this inconsistency. Some of the explanations for the contradiction between research findings and practice may lie in what is known as the “*illusion of group effectiveness*.”

1. *Lack of distinction between process and outcomes:* The participants’ ability to disti-

4 brainstorming

nguish between their satisfaction in the process and its outcomes is distorted by the magic spell of their experience. In other words, the participants' reported satisfaction in the process is derived from their participation in the brainstorming process, leading them to overevaluate the results compared with individuals who worked on their own and generated the same ideas. Participants in a brainstorming process indeed indicate a larger degree of satisfaction and enjoyment from the experience, compared to nominal groups.

2. *Group experience:* Working in a group causes members to feel that something new was created in the course of the brainstorming session. To justify the efforts invested in the group process, individuals tend to believe that the group produced something in which all members had a part. In their evaluation of group outcomes, participating individuals do not distinguish between their ideas and the ideas of others. They are usually under the impression that they were the source of more ideas than was actually the situation. This misperception leads to an evaluation of an effective and satisfying process. In addition, owing to the high attentiveness, group members internalize the ideas of their fellow members, creating a false belief that more ideas were generated than would have been generated if each worked alone.

Other factors contributing to the illusion of the effectiveness of the brainstorming process cannot be identified and manipulated under laboratory conditions. A major reason for the method's popularity is found in the organizational functions served by the process, and the organizational benefits that are its result (Sutton and Hargadon, 1996).

- *Support of common organizational memory:* Brainstorming sessions help organization members acquire, store, retrieve, modify, and combine knowledge of various solutions to the problems they face. The sessions create opportunities to add new knowledge and solutions to the organizational memory. Furthermore, such sessions serve as an efficient means of distributing knowledge

among organization members, reinforcing the knowledge of older members, and imparting organizational knowledge to new members, including solutions generated previously.

- *Diversification of ability:* Participants in brainstorming frequently define it as a pleasant and fun experience. Part of the enjoyment is related to the possibility of working with others in an unrestricted manner. For most participants, the session is a social encounter, an opportunity to share experiences and discharge everyday stress. Another benefit is the opportunity to use and learn new technologies and knowledge. In other words, brainstorming affords participants the opportunity to experience diversity and interest that is not always present in their everyday functions.
- *Competition over status:* Brainstorming is an important organizational arena in which competition over status takes place, based on the competencies of the group members, who meet for a predetermined session or sessions to concentrate on a specific problem. The rules of the brainstorming session are known to all: although bad ideas are not criticized, good ideas are praised, creating an opportunity to receive less threatening feedback from organization members.
- *Impressing clients:* Brainstorming is an opportunity for an organization to convey the competencies of its members. Quite often, clients are impressed by creativity expressed in meetings and they love the positive atmosphere. Organizations use this process to show their client that they understand his or her problem, and that they rely on a wealth of experience to arrive at the best solution. Brainstorming is also an efficient forum for the client to present his or her problems and gather ideas from a number of participants simultaneously.

Moreover, the statement "everybody uses brainstorming" is not necessarily entirely correct. First of all, a great deal of what is called *brainstorming* is no more than efficient teamwork. Let us recall an example we are all familiar with: students studying together for an exam. Not only are they not "brainstorming"

or raising far-fetched ideas, but what they are doing is actually the opposite. They solve the problems by focusing on each problem at hand. Imagine a Harvard Business School case analysis or solving a complex mathematical function—do students raise random ideas? Do they raise ideas that are detached from each other? Do they defer judgment? Of course, they do not. Even engineers who meet to solve problems do not conduct brainstorming sessions, though they may call it that. In practice, in most of their meetings, they conduct efficient discussions to examine various alternatives, and assist each other in solving the problem. In such a process, the group effect stems from focusing rather than from brainstorming.

The physicist Tom Hirschfeld once said “The second attack on the same problem should be from a completely different angle.” Apparently, the group encounter does have a value that is not necessarily relevant to the mechanism of brainstorming. This can be illustrated by the story of the company that decided to eliminate its coffee corner. Exhibiting great efficiency, the company appointed an individual to bring coffee and cookies to anyone who sends a request through the company’s Intranet. The company executive thought that by eliminating the need for the company’s engineers to leave their desks, their efficiency would be improved, and he or she could also convey the consideration that the company shows its employees by affording them a higher degree of convenience. After a number of months, the executive found that eliminating the random meetings at the coffee machine prevented an exchange of knowledge and opinions, had a detrimental effect on the engineers, and their productivity fell.

This story indicates a possible means of reconciling our conflicting data. Perhaps the brainstorming method of discussion is not particularly effective for the generation of new ideas, but apparently it, or the encounter it creates, exposes previously untapped ideas of the organization’s members. Imagine that an organizational member is facing a problem similar to the one previously solved by another member on the floor below. In an encounter such as brainstorming, he or she would be able to share his or her accumulated knowledge, the successful and failed tests that he or she conducted, and

perhaps the directions that he or she examined and found potentially beneficial.

If so, how can we reap the benefits of brainstorming while avoiding its relative shortcomings, as found in laboratory experiments? In this context, we would like to present some new insights relating to brainstorming and suggest how a more advanced version of this approach may be used to the benefit of organizations. In electronic brainstorming (EBS), a recently introduced electronic version of brainstorming (Gallupe *et al.*, 1992), brainstorming sessions—rather than taking place aloud and in a single location—are conducted by virtually merging nominal groups and opening a new channel of idea-sharing and knowledge transference. Each organization member sits at his or her own desk, electronically connected to the others (sometimes from other plants or organizations). Participants generate ideas on their own and send them to the general pool, while continuing to develop their train of thought and generate more ideas on the theme. When they feel that they are ready to investigate the ideas of others, they download them from the pool. These inputs lead to new responses on their part or to further development or generation of ideas. This virtual neuron storm has a number of advantages: individual members can control their retrieval of the ideas of other participants and choose the timing for reflection on these inputs, thus avoiding the distraction effect. Outside observers can add new instructions or guidelines. In a global brainstorming process that was conducted through the Internet at the initiation of a well-known food company, corporate executives observed the exchange of ideas in real time, on a giant screen. They concurrently conducted a discussion to assess and filter the various ideas and even made real-time decisions.

Empirical findings reflect the success of EBS, both absolutely and relative to “regular” brainstorming. Large groups of participants generated more ideas than individuals working alone (in nominal groups). In addition, the quality of the EBS-generated ideas was rated as higher. The size of the EBS group enables a quick and sharp compilation of the conceptual capital in the organization. Apparently, the absence of inhibiting social phenomena that characterize

group processes during brainstorming and the ability to concentrate and develop a train of thought without interruption, avoid the pitfalls of brainstorming while enhancing its benefits. Although it is too early to claim that advanced EBS has made significant inroads into managerial practice at the cost of traditional brainstorming, its superiority has been sufficiently demonstrated to allow us here to seriously recommend its integration in the problem-solving modes of organizations. Nevertheless, we should remember that despite EBS' superiority in idea generation, it lacks the social encounter that has been found to be an important side-benefit of conventional brainstorming encounters.

Another interesting finding in regard to recent creativity studies (not conducted in the context of group research) relates to the perception that the constraints of a problem encourage the production of more creative ideas (Smith, Ward, and Finke, 1992). Constraints provide a focus for the brainstorming session and transform it into "focused storming." Brainstorming synergies are not a result of distractions. They are based on a number of minds working in a well-defined direction. In this context, we can mention that studies of group decision-making process indicate that when a discussion is well managed according to a decision-making model, the group has a higher value than the sum of its members. Findings such as these lead us to hypothesize that when the problem is constrained and well defined, even subject to complete freedom of expression, anarchy is not a possible outcome. In our opinion, a brainstorming session should be conducted to generate solutions to well-defined problems, with a clear set of criteria for success. In this case, information exchange, conceptual capital, and directing the storm of ideas to a target-focused channel contribute to organizational performance. Conversely, when problems

are ambiguous and ill defined, such as problems relating to new-product innovation, focused storming is preferred.

To make the most of brainstorming, it is imperative to define the problem at hand and the goals of the encounter beforehand and in a precise manner. Brainstorming is one of the easiest methods to implement, and although many different ways of doing this are available, these should be consistent with the context and should fit the situation. It is important to remember that brainstorming is not always the only or the preferred option.

concept testing

Kenneth B. Kahn

Concept testing represents those activities undertaken during the concept evaluation phase of the new-product development process for the purpose of assessing and incorporating customer opinion before committing substantial funds (see also PRODUCT TESTING) (Moore, 1982). During concept testing, general consumers, current customers, and/or potential customers are asked to evaluate a new product concept by giving their opinion on whether the concept is something that they may have interest in and would likely buy. Other questions to be asked during a concept test can include the following: Why is the concept (or not) appealing? What are the main strengths of the product concept? What are the key weaknesses of the product concept? What are the suggestions for improving the proposed product concept (Cooper, 1993)? Focus groups, in-person interviews, telephone interviews, mail surveys, and online surveys are common data collection methods in the course of concept testing (Peng and Finn, 2008).

TYPES OF CONCEPT TESTING

There are four general types or approaches for conducting a concept test: the narrative concept test, the pictorial concept test, the prototype concept test, and the virtual concept test. The narrative concept test involves a text description of the concept being presented to consumers for their opinions. There are two styles in which the text description or concept statement can be written: noncommercialized and commercialized. A noncommercialized concept statement, also called a *stripped description*, is a simple factual statement about a proposed product concept that contains a minimum of attributes; a commercialized concept statement, also called an *embellished description*, is a persuasive statement about a product concept written in such a way as to promote the product and its attributes similar to how a product would be promoted at launch. Lees and Wright (2004) find marginal differences when comparing the attitude and purchase intention responses to the two concept statement styles.

Instead of text, the pictorial concept test involves a black and white or color drawing

being presented to consumers for their opinions. The prototype concept test involves the customer being shown and possibly being asked to handle a facsimile of the product and/or an actual working version of the product (see PROTOTYPE). The benefit of a prototype is that the consumer can witness and experience the product firsthand. The virtual reality concept test is when the consumer views a computer image of the product and possibly interacts with a virtual prototype, thereby virtually witnessing and experiencing the product.

While there are four types of concept tests, product concepts are typically evaluated through a combination of these concept tests. For example, a concept test can be staged to observe consumers' evolving opinions as a result of being first exposed to a narrative text statement (narrative concept test), then to a picture (pictorial concept test), and finally to a working prototype (prototype concept test). Each subsequent test provides additional information that the consumer can process and respond to. In choosing between a narrative concept test and a pictorial concept test, one should consider whether the research objective is to show concept test participants how the product looks so that they can gauge an opinion, or whether it is better to have concept test participants attempt to visualize what the product would/should look like. The latter may be useful in designing an idealized version of the product according to consumer opinion.

product testing

C. Anthony Di Benedetto

When a product is in the technical development stage, the product team must ensure that it is on track to meet objectives. In earlier stages, before a physical prototype is available, the team would likely have conducted concept tests with potential customers (*see* CONCEPT TESTING). Now, however, at least an early prototype is available for customer trial, and valuable information may be obtained from customers as to their initial reaction to the physical prototype, their level of satisfaction with the prototype, and also their likes and dislikes. This information can be used to further refine the prototype as well as to assist in making other marketing decisions, such as brand name, package design, and price levels. We begin with a brief discussion of prototypes and then move to the objectives and methods of product testing.

PROTOTYPE DEVELOPMENT¹

There are different levels of prototypes, each used at different stages in product testing. The term *focused prototype* refers to a nonfunctioning or limited-functionality prototype, which product developers use to assess early customer reactions. After further development, a “comprehensive prototype,” or a basically complete version, is prepared and can also be taken to market to make final adjustments to the product and supporting elements such as price or brand name. A cell-phone manufacturer may make several nonfunctioning phones out of wood or foam, and see whether customers like the size, how it feels in the hand, how big the screen is, how close together the buttons are, and can make appropriate changes. Many of these can be made at very low cost, until the firm has zeroed in on customer likes while eliminating the dislikes. In fact, the more radical the new product is, the more the manufacturer may want to use a series of focused prototypes to better understand elusive customer requirements. This process is sometimes called *probe and learn*. For example, Iomega reportedly went rapidly through about 50 nonfunctional prototypes of their new high-storage disk drive,

which eventually became known as the *Zip Drive*, before settling on one that customers liked (Lynn and Reilly, 2002). Similarly, Charger Electric Bicycles built a succession of nonfunctioning bicycles out of wood and plastic to assess preferences for appearance, performance, and weight. They eventually also built a crude functional prototype (i.e., not beautiful, but it did work well enough to get customer trial reactions) and continued to make improvements to it. Eventually, all the technical and cosmetic trade-offs were made and the bicycle was commercialized (Mascitelli, 2000).

Of course, prototypes can also be developed using computer-aided design and manufacturing (CAD/CAM) techniques (*see* PRODUCT DESIGN). Using a technique sometimes called *rapid prototyping*, a three-dimensional computer model is converted into a hard plastic prototype, which can be evaluated by customers. If customers like it, the prototype can become the “master” from which the molds for the manufacturing process can be built (Van Dierdonck, 1990). Car companies routinely design cars using CAD/CAM and can execute thousands of virtual “crash tests,” thus reducing the need for expensive physical prototype manufacture (Thomke, 1998; Thomke and Fujimoto, 2000). Nevertheless, some car companies such as BMW will complement CAD/CAM car design with traditional, painstaking clay models, to get the minute design features just right (Bangle, 2001). Fixing these problems at this early stage minimizes the need for expensive retooling later in the process.

PRODUCT-USE TESTING

Now that the product prototype has been built, we can proceed to product-use testing. This step is sometimes called *beta testing*, a term that originated in the computer software industry (alpha testing means testing with internal employees, beta testing with outsiders). Customer needs can be very complex, and it may be necessary to conduct multiple product-use tests to come up with a successful version of the product, especially in the case of a radically new product. General Electric, for example, tested four different versions of its computed tomography (CT) scanner—each offering

2 product testing

different functionality to the physician—before hitting upon the full-body scanner that became the marketplace success (Lynn *et al.*, 1998). Careful product-use testing will reveal problems that may be easy to rectify but might otherwise not be identified until it is too late. According to the web site www.baddesigns.com, Polaroid once launched a children's camera that could be opened (thus ruining the film inside) if the child simply pressed a button (Crawford and Di Benedetto, 2008, p. 352). Somewhat unexpectedly, the problem was that the camera was too easy to open! Better product-use testing might have found and corrected this problem.

Knowledge gained from product-use testing².

There are four categories of knowledge that can be obtained from the product-use test: preuse sense reactions, early use experiences, major benefit results, and diagnostic information.

As the name implies, preuse sense reactions are customer sensations of the product even before they have a chance to evaluate it. A carmaker will realize that the clean, inviting appearance of the showroom, and the helpfulness and expertise of the sales staff, will make a good first impression and help in creating a positive customer sensation. Alternatively, a product may make a promise that customers will perceive as “too good to be true.” A new headache remedy that is both very gentle and very effective might meet customer skepticism, despite the fact that it really works. The product-use test is an opportunity to assess the believability of the claim, and to take corrective action. For example, at the time of the iPhone launch if the average person would find it hard to believe that it really is a music player, photo album, and internet device built into a phone, then perhaps demonstration promotional campaigns are required in order to show the product in use.

Early use experiences are also assessed at this stage. The first few features that the user will be able to judge will be, for example, whether the product is easy to use, whether there are any apparent problems while using it, whether the product seems to do what it is supposed to do, and any other early impression.

The heart of the product-use test is the assessment of major benefits (*see* VALUE PROPOSITION). In a traditional beta test of, say,

a new piece of banking software, the developer will get the product adopted at a given number of customer sites, and the product is put to use. Users may be given checklists to assess specific benefits that should be provided by the new software (such as whether it performs as advertised, whether it is “robust” to mistaken entries, whether it provides cost benefits, etc.). Notice that the goal of the product-use test is not necessarily to test specifically if the product meets customer needs, but rather to make sure it provides the benefits it is supposed to.

While traditional product-use testing involves a small number of customer sites, this is changing, notably in computer software. Most of us have downloaded free beta versions of new software, with the usual disclaimers. When a software developer releases beta versions for download, there may be thousands of customers who download and try the software. In a classic case, both Netscape and Microsoft were developing new Internet software in 1996. During this period, both firms were releasing limited-functionality alpha versions on company web sites to employees, followed by multiple beta versions to customers. Needless to say, Microsoft employees were downloading Netscape beta versions and vice versa, so as to keep track of competitive developments. During this period, Microsoft went from having virtually no presence in this market to having a fully developed early commercial release of the Internet Explorer (Iansiti and MacCormack, 1997).

Finally, the manufacturer also seeks to obtain diagnostic information from the product-use test. The users at the customer site may suggest performance improvements, or verify whether the product's delivered benefits match the intended positioning of the product. Alternatively, warning signs may be identified: customers may report that the new product is hard to understand or they found the presentation of results difficult to interpret.

It should also be noted that some firms do not go through all of these steps in such a linear fashion. Some managers feel that they get sufficient marketplace information with a minimum of testing. As an example, during the period when it managed the Snapple line of drinks, Triarc managers dropped all product-use testing, relying on their own instincts for new

flavors and trying these themselves—in short, they conducted small-scale alpha testing only, followed immediately by a launch. The management, no doubt, felt that the downside risks of launching a weak product were not too steep, and indeed had success with this method; the popular Snapple element brands (Rain, Sun, and Fire) were launched during this time (Deighton, 2002).

Product-use testing considerations. The first rule for effective product-use testing is that the product being tested should be as similar as possible to the product that will eventually be manufactured and marketed. Manufacturers have been known to product-use test a pilot version of the product that is far higher in quality than the mass-produced product ultimately launched. Related to this, if there is any possibility of customer misuse of the product, the product should be tested by real consumers in real situations, rather than under exacting laboratory conditions that would never exist in reality. A new instant coffee that tastes perfect when made with distilled water and spooned out with chemical measuring instruments might be terrible when carelessly prepared (for more similar misuses of product-use testing, see Lavidge, 1984).

There are other guidelines as well. The product developer must carefully specify the performance requirements to be used by the customer site. For example, a term like *user-friendly* can mean different things to different people, so unless it is clearly defined, it is open to multiple interpretations, rendering the results meaningless. In addition, timing is also a factor. Running the product-use test too late in the development process guarantees that time to market will be adversely affected, and delays will occur, if the developer tries to fix problems uncovered during the test. However, if the test is conducted too early, there may be too many bugs still in the product and some bad word of mouth publicity may take place. Finally, if the product-use test results are poor, they should not be ignored. All results from the product-use test are valuable and should be evaluated and used to improve the product, regardless of how negative they are (Stoy, 1996).

core competencies

Shikhar Sarin

INTRODUCTION

In their highly influential book “Competing for the Future,” Hamel and Prahalad (1994) suggest that in the short run, large diversified firms derive their competitiveness from the price and performance attributes of their current products. However, over time, competition forces most firms to converge on similar standards of cost and quality, eroding any differential competitive advantage. In the long run, the real source of competitive advantage lies in the ability of the senior managers to consolidate organization-wide technologies and skills into competencies that create unanticipated products; competencies that allow firms to build products faster and at a lower cost than competitors, and to adapt nimbly to changing environments (Hamel and Prahalad, 1994; Prahalad and Hamel, 1990).

DEFINITION

Core competencies are collective learnings in an organization that result from a unique coordination of diverse production skills and/or the integration of multiple streams of technologies (Prahalad and Hamel, 1990). Unlike physical assets, core competencies do not diminish with use, nor do they deteriorate over time; instead they are enhanced as they are applied and used (Hamel and Prahalad, 1994).

COMPETING FOR THE FUTURE

Identifying core competencies. The notion of core competencies has been criticized for being too abstract, ill defined, and difficult to implement. Managers often have a hard time identifying core competencies of their firms. However, Prahalad and Hamel (1990) offer three tests that can be applied for identifying core competencies in an organization:

- Core competencies provide potential access to a wide variety of markets.

- Core competencies make a significant contribution to perceived customer benefits of the end product.
- Core competencies are hard for competitors to imitate.

Hamel and Prahalad (1994) suggest that few firms are likely to be world leaders in more than five or six fundamental competencies. Those that name a laundry list of competencies are really not identifying their *core competencies* as subject to the three tests listed above.

Roots of competitive advantage. Battles for global leadership are waged on three different planes: core competence, core product, and end products (Hamel and Prahalad, 1994). It is critical for managers to understand and appreciate the distinction between these levels. Core products are physical manifestations of one or more core competencies. They are the tangible link between core competencies and end products. Core products are components or subassemblies that contribute to the value of multiple end products. For example, Honda's core competence in design and development manifests itself in the form of the global leadership in engines and power trains. These engines and power trains then lead to a proliferation of end products for Honda in markets as diverse as cars, motor cycles, generators, lawn mowers, compressors, and so on (*see also* PRODUCT PLATFORMS).

Prahalad and Hamel (1990) suggest that one way to distinguish between a core competence, core product, and end product is to visualize a diversified firm as a tree. The trunk and major limbs of the tree represent the core products; the smaller branches are the strategic business units (SBUs) (*see* ORGANIZING FOR INNOVATION); the leaves, flowers, and fruits represent the end products. The root system of this tree, which provides its underlying strength, nourishment, stability, and sustenance, is the core competence. While competitive advantage in end products is relatively short-lived, nurturing of core competencies and core products can result in long-term and sustainable competitive advantage.

Rethinking the corporation for the future. Most large diversified firms are organized as portfolios

2 core competencies

of relatively independent and autonomous SBUs. Owing to the primacy of the SBU structure, resources, technologies, talent, and knowledge become trapped in isolated pockets within large organizations, with few opportunities for cross-fertilization. Moreover, in large diversified organizations, no entity is responsible for developing a comprehensive strategy that transcends traditional SBU boundaries. Because of imprisoned resources, innovation becomes bounded and is limited to marginal line and geographic extensions. This results in a chronic underinvestment in, and underdevelopment of, core competencies and core products (Prahalad and Hamel, 1990).

Managers of diversified organizations spend a disproportionate amount of their time and energy in competing over end products, while overlooking the far more critical levels of competition in core products and core competencies

(Hamel and Prahalad, 1994). To claim global leadership, executives of diversified firms will need to break free from the “tyranny of the SBUs,” and start regarding the organizations as portfolios of core competencies and core products, rather than as a collection of discrete businesses.

competitive advantage

Shikhar Sarin

INTRODUCTION

Two key issues guide the choice of competitive strategy for a firm: attractiveness of the industries for long-term profitability, and the determinants of relative competitive position within an industry (Porter, 1985). The ensuing discussion focuses on the latter.

DEFINITION

Competitive advantage is a firm's ability to grow in spite of competition. Best (2004, p. 387) defines *competitive advantage* as the relative advantage one business has over another that is sustainable and translates into a benefit that is important to target customers. There are two basic types of competitive advantages: cost leadership and differentiation (Porter, 1985). Cost leadership stems from the ability to offer lower prices than competitors for equivalent benefits; whereas, differentiation stems from the firm's ability to provide unique benefits that more than offset the premium price charged by the firm. Attaining competitive advantage requires a firm to make choices regarding what kind of advantage it seeks, and the scope within which the firm seeks to achieve it. Porter (1985) contends that combined with the choice of competitive scope (or the range of a firm's activities), these two types of competitive advantages can lead firms to three different kinds of generic business strategies for achieving above-average profitability.

GENERIC BUSINESS STRATEGIES

Cost leadership. In this type of strategy, a firm sets out to become *the* low-cost producer in its industry by selling a standard, no-frills product (Porter, 1985). The firm operates with a broad scope and serves many industry segments. The cost advantage of the firm can stem from many different sources such as economies of scale, control of proprietary technology, preferential access to resources, and so on. However, a cost leader must achieve parity or proximity in the basis of differentiation relative

to its competition. In other words, the cost leader should either offer an identical product offering to competitors, at a lower price, or a different combination of product attributes that is equally preferred by buyers (*see also* VALUE PROPOSITION). A successful implementation of this strategy requires that the firm be *the only* cost leader in an industry. If there is more than one firm competing on this strategy, it can lead to disastrous consequences for industry structure and overall profitability.

Differentiation. Under this strategy, the firm selects one or two dimensions that the buyers value and uniquely positions itself to meet those needs – while charging a premium price for such uniqueness (*see* PRODUCT POSITIONING). The bases for differentiation can arise from several sources, such as the product itself, the method of delivery/distribution, and the marketing approach. A differentiator must achieve cost parity or proximity with its competitors by reducing cost in areas that do not affect differentiation; otherwise its price premium will be neutralized by inferior cost structures (Porter, 1985). Porter suggests that since differentiation is based on a firm distinguishing itself on attributes that are different from its competitors, there can be more than one successful differentiator in an industry.

Focus. This strategy chooses a narrow competitive scope within an industry (i.e., a niche). The focuser selects a segment or a group of segments in the industry, and seeks to achieve competitive advantage in the target segment(s). In other words, the focuser optimizes its strategy on a narrow scope of activities, even though it may not enjoy a competitive advantage overall. This strategy rests on differences between the target segment(s) and other segments in the industry. The target segment must have unusual needs or preferences that are poorly served by broadly targeted competitors. The focuser can exploit these differences and achieve competitive advantage by dedicating itself to serving these segments exclusively. Porter (1985) suggests that there are two variants to this strategy: differentiation focus and cost focus. In differentiation focus, the firm seeks differentiation in its target segment(s) by exploiting the special needs of

2 competitive advantage

buyers in the target segment(s). Cost focus, on the other hand, exploits the differences in cost behavior of the target segment(s). Porter suggests that there is room for several sustainable focus strategies in an industry, provided that focusers choose different target segments.

SUSTAINABILITY OF COMPETITIVE ADVANTAGE

Sustainability of these generic strategies demands that a firm's competitive advantage resist erosion by competitive action or industry evolution. Porter (1985) suggests that cost leadership is not sustained if competitors imitate, technology changes, or bases for cost leadership erode. Cost leadership is also hard to sustain if the cost leader loses proximity in differentiation, or cost focusers achieve even lower costs in segments. Similarly, differentiation is not sustainable if competitors imitate, or bases for differentiation erode. Differentiation strategy is at risk if the differentiator loses cost proximity, or differentiation focusers achieve even greater differentiation in segments. In addition to dangers of imitation, focus strategy is also at risk if the target segment(s) become structurally unattractive or the demand disappears. Broadly targeted competitors can overwhelm the focusers if the target-segment differences from

other segments narrow down, or the advantages of a broad line increase. Focusers can also be at risk if new focusers further subsegment the industry.

Ghemawat (1986) notes that competitive advantage can be sustained by not ignoring any contestable advantage that may crop up. He argues that sustainability is greatest when it is based on several kinds of advantages rather than just one. To create a sustainable competitive advantage, one must be able to preempt competitors, especially in industries that offer potent first-mover advantage (Ghemawat, 1986; *see also* FIRST-MOVER ADVANTAGE). In addition, competitive advantage in one industry can be enhanced by interrelationships with business units in other industries (Porter, 1985; *see also* CORE COMPETENCIES).

locale of innovation

K. Sivakumar

INTRODUCTION AND DEFINITIONS

For the purpose of this discussion, “local” means involving only one country. “Transnational” means involving more than one country and, typically, several countries. In that sense, “transnational” is used synonymously with “global,” “multinational,” “international,” “cross-country,” “multicountry,” and similar terms. “Innovation” can be conceptualized as (i) the process of developing new products (Crawford and Di Benedetto, 2006; Belliveau, Griffin, and Somermeyer, 2002) or (ii) the new product outcome itself (see INNOVATION TYPOLOGIES). “Product” is used as a generic term to include goods, services, ideas, and processes, including both radical and incremental products (see GLOBAL PRODUCT DEVELOPMENT). Combining the two concepts, the phrase “local innovation” can mean that (i) the development of the innovation is locally done or (ii) the innovation caters to the local markets; similarly, the phrase “transnational innovation” means that (i) the development of the innovation is transnational or (ii) the innovation can cater to transnational consumption. The following typology helps us understand the entire gamut of meanings of these concepts.

| <i>Locus of development</i> | |
|-----------------------------|---------------|
| <i>Local Transnational</i> | |
| <u>Locus of</u> | Local |
| <u>consumption</u> | Transnational |

SCOPE AND MEANING OF LOCAL AND TRANSNATIONAL INNOVATION

Although most innovations are associated with business entities, it must be realized that innovation can be a social phenomenon and can be developed exclusively by companies, partially by companies in association with universities and/or communities, or entirely by universities and/or communities.

With respect to innovations in organizations and the various natures and extents of globalization (e.g., from a small manufacturer supplying parts to a US company to truly multinational companies such as IBM with operations and suppliers in several countries and diversified companies with different kinds of businesses scattered all over the world), the phrases “local innovation” and “transnational innovation” must be understood in their proper context. For example, a local innovation process involving several divisions in a large company like General Electric may involve more complexities than a transnational innovation process of new software development between two different companies in two different countries or two teams of the same company located in two different countries (see CROSS-FUNCTIONAL TEAM; VIRTUAL TEAMS). If a local innovation is an incremental innovation, the original innovation, to which minor modifications are made, could have been a transnational innovation or a local innovation; a local innovation might also simply be a product that is modified locally to cater to local needs (Bartlett, Doz, and Hedlund, 1990; Bartlett and Ghoshal, 1998).

Similarly, when discussing the process of transnational development of innovation (Eppinger and Chitkara, 2006; Nakata and Sivakumar, 1996), the original innovation (e.g., a patent for the discovery of a molecule) could have been developed locally in one country, but subsequent innovation (e.g., drug development using the patent to develop medicines to cure illnesses) may be transnational. Another example is a multinational company that uses all its resources in multiple countries to develop a water-purification system (i.e., a transnational innovation process) to cater to the specific water composition in an African village (to be consumed as a local innovation).

When we move away from innovations that companies spearhead into the realm of societal changes (e.g., modification of a teaching method to address the lack of technology in a developing country’s village), a transnational innovation is modified to become a local innovation. Sometimes local innovation also expands to include regions. For example, the concept of microcredit can be considered a local innovation developed in a single developing country but can become

a transnational innovation if several countries in a given region and beyond adopt it. Similarly, systems to organize rural farmers into powerful cooperatives can be local when based on what is done locally in a particular country (e.g., India) but also can become transitional (e.g., Pakistan and Sri Lanka).

Another aspect to consider is the production of the innovation – the innovation can be locally or transnationally developed for local or transnational consumption and can be produced in each local market or in transnational facilities. In this case, the two-by-two matrix developed earlier could be converted into a three-dimensional matrix to include development, production, and consumption. Interestingly, the production process may involve local modifications to the innovation (i.e., local innovation), thereby further developing incremental innovations.

CONCLUSION

As the movement of people, products, and ideas across countries is increasingly becoming a norm for business and nonbusiness organizations, in particular, and society at large, in general, innovation activities and the outcomes of such activities are becoming increasingly transnational (Cooper, 2009). While purely local innovations will become more of a rarity, transnational innovations will involve different levels of involvement by people and organizations across different countries and/or firms.

integrated product development

Fred Langerak

Integrated new-product development is a contemporary managerial approach for improving new-product development performance through the overlap (partial or complete parallel execution) of and the interaction (exchange of information) between activities in the new-product development process (Naveh, 2005). Since overlap and interaction increase the need to coordinate activities, integrated product development requires the systematic employment of teams consisting of members from all relevant disciplines to integrate and concurrently carry out the critical activities to efficiently develop a new product that satisfies customers' needs.

Teaming involves the establishment of cross-functional teams for the purpose of better integrating and coordinating activities between different organizational units, as well as coordinating the organization's interaction with other firms (*see* CROSS-FUNCTIONAL TEAM). The emphasis is on the early and active involvement of all internal (e.g., design, manufacturing, marketing) and external (e.g., suppliers and customers) stakeholders to create ideas and transform them into designs (*see* PRODUCT DESIGN), prototypes (*see* PROTOTYPE), and plans for product launch (*see* LAUNCH STRATEGIES) (Koufteros, Vonderembse, and Doll, 2002). In this way, problems that might emerge in the later stages of the development process are taken into consideration in the earlier stages when they can still be dealt with at a lower cost and without causing serious delays.

Among the benefits of integrated product development reported in the academic literature is reduced development time and reduced new-product goal failure. In the business community, integrated product development is also held to promote better knowledge sharing between different functional groups, enhanced flexibility, cost savings, clear focus on risks, and improved new-product quality (Nellore and Balachandra, 2001). Frequently reported drawbacks of integrated new-product development are lower task specialization and decreased project innovativeness, especially if it is applied in the early stages of a development project.

Integrated product development studies fall into four categories of research (Gerwin and Barrowman, 2002). The organizational design approach investigates integrated product development in terms of structural adaptations in new-product strategy and project organization and execution to environmental and technological changes. In the information-processing approach, integrated product development is viewed as a problem-solving process that allows an organization to generate, disseminate, and use information on market opportunities and technological possibilities, and translate the resulting knowledge into a product-design solution that meets customer requirements. Integrated product development is also studied as the application of total quality management principles from manufacturing to new-product development, with integrated product development concepts such as virtual incorporation of customers and suppliers into cross-functional teams having their roots in this line of research. Finally, integrated product development is researched from the practices that firms use to achieve integrated product development, such as quality function deployment, rapid prototyping, digital product modeling, and joint design reviews (Boyle, Kumar, and Kumar, 2006).

Integrated product development is used in about 65% of all development projects, albeit in various manifestations such as design for manufacturing, concurrent engineering, early customer involvement, and time-based competition, and as such has become the standard for managing product development (Griffin, 1997). Many researchers suggest that the effectiveness of integrated product development practices depends (heavily) on organizational factors and project characteristics, such as the organization's innovative climate, senior management support, project organization, and leadership (*see* LEADERSHIP ROLES IN PRODUCT DEVELOPMENT), the complexity of the organization's development activities, and the project's newness. However, there exists no empirical consensus on the precise influence of these contingencies on the impact of integrated product development on new-product development performance.

Regardless of the contingencies involved, it is clear that while integrated product development

2 integrated product development

efforts should be initiated, planned, and led from the top down, they should be executed from the bottom up to foster ownership among cross-functional team members. Team members should place emphasis on understanding customers' needs and the processes required to design and deliver a product solution, aligning development projects with business strategy, facilitating early involvement and parallel design, designing products and manufacturing and support processes in parallel, and involving customers and suppliers early in the development process.

ACKNOWLEDGMENT

The author thanks Pinar Cankurtaran for her insightful and helpful comments.

product-line strategies

Jeffrey B. Schmidt

PRODUCT-LINE DEFINED

A product line consists of multiple products (or services) that fulfill the same or similar needs and wants. Normally, they function in a similar manner, and they may use similar technologies, be sold to the same customers, and use the same distribution channels. Product lines can be described by their breadth and depth. Various branding issues are also related to product-line decisions.

PRODUCT-LINE BREADTH AND DEPTH

Decisions about the breadth and depth of product lines are important. The breadth of a product line refers to the number of different lines an organization offers. As Figure 1 shows, product-line breadth may be described as either narrow or broad. Nike’s product line is broad since it offers shoes, apparel, hockey equipment, golf equipment, and other products. Conversely, Palm is an organization that offers a narrow line of products consisting mainly of smart phones, electronic organizers, and various accessories for these devices.

More important are decisions about the depth of a product line, which refers to the number of items in that line. Product-line depth may be described as shallow or deep. As an example, Apple has a shallow line of iPhones. There are two colors available (i.e., black or white) and two different storage capacities (8 or 16 GB) for a total of four different iPhone models. With respect to cars, BMW has a deep line of products

in its “3 series” automobiles. There are at least 17 different 3-series models.

BRANDING ISSUES (FAMILY BRAND, COMPANY BRAND)

In addition to the breadth and depth of product lines, the branding strategy should be carefully considered as it is important for product growth strategies and launch strategies (see GROWTH STRATEGIES; LAUNCH STRATEGIES, respectively). Rao, Agarwal, and Dahlhoff (2004) extended the branding taxonomy of Laforet and Saunder’s (1994), and categorized branding strategies into three types – corporate branding, house of brands, and mixed branding, which are defined in the following sections.

Corporate branding. Here the corporate name is dominant in endorsing all or part of the firm’s product and service brands. At a minimum, the corporate name is an element of the product brand names. This holds throughout all its subsidiaries and at all company levels. Examples of companies that employ this strategy are Hewlett-Packard, Motorola, and Federal Express.

Mixed branding. Organizations typically employ a set of house or family brands, such as subsidiary names, in their brand portfolio, in addition to using the corporate name for certain products. Brands with names other than the organization’s name are typically strong and significant to the organization. Pepsi is an example of such a firm because apart from its flagship brand, it operates with Mountain Dew and Aquafina, and its subsidiaries Tropicana and Frito-Lay use individual brands at the product level (e.g., Doritos and Ruffles).

House of brands. Here the organization does not use its corporate name or the name of its subsidiaries. Instead, it uses individual brand names to market its products. Companies such as Unilever and P&G keep their corporate name in the background and use individual brands for their product lines.

Table 1 provides examples of firms following each of these branding strategies and their selected brands.

| | | Product line breadth | |
|--------------------|---------|--|---|
| | | Narrow | Broad |
| Product line depth | Shallow | Few product lines with a few items in each | Many product lines with a few items in each |
| | Deep | Few product lines with many items in each | Many product lines with many items in each |

Figure 1 Product-line breadth and depth.

Table 1 Examples of branding strategies.

| Corporate Branding | | Mixed Branding | | House of Brands |
|--------------------|----------|---|----------------------|--|
| Company and Brand | Company | Selected Brands | Company | Selected Brands |
| Porsche | Gillette | Gillette, Oral-B, Duracell, Braun, Waterman | P&G | Pampers, Crest, Tide, Ariel, Bounty, Always, Febreze |
| AT&T | The Gap | The Gap, Banana Republic, Old Navy | Darden Restaurants | Red Lobster, Olive Garden, Bahama Breeze |
| Dell | 3M | 3M, Scotchguard, Thinsulate, Scotch | Bristol-Myers Squibb | Clairol, Aussie, Herbal Essences, Viactiv, Boost |

GE/McKinsey matrix

Ashish Sood

The GE/McKinsey matrix is a nine-cell portfolio matrix tool developed by McKinsey & Company for GE's large portfolio of strategic business units (SBUs) (see Table 1) (*see also* PORTFOLIO MANAGEMENT). The aim of the portfolio analysis is to develop a strategy to identify SBUs that should be prioritized in investment and growth strategies, and to review SBUs that should no longer be retained. The two factors used in the analysis are the attractiveness of the relevant industry and the SBU's competitive strength within that industry.

The vertical axis is the industry attractiveness, which is determined by a combination of factors such as market growth rate, market size, industry profitability, industry rivalry, and global opportunities (*see also* GROWTH STRATEGIES). The horizontal axis is the strength of the business unit, which is determined by a combination of factors such as market share, growth rate, brand equity, channel equity, and profitability (*see also* MANAGING MATURE PRODUCTS). Managers may also include a different set of factors including the relative importance of each factor to determine a quantitative measure of each axis.

The nine cells in the matrix can be grouped into three major segments. Cells 1–3 comprise the first segment, which includes strong business in an attractive industry. Cells 4–6 comprise the second segment, which includes SBUs with medium attractiveness either because the firm has strong SBUs in an unattractive market or weak SBUs in an attractive industry. Cells 7–9 comprise the third segment, which includes weak

SBUs in unattractive markets. Managers can formulate appropriate strategies to strengthen their positions in the first segment, to move from the second segment to the first, and to divest SBUs in the third segment (*see also* PRODUCT DIVERSIFICATION).

The matrix may also be plotted graphically. The two axes are industry attractiveness and business unit attractiveness respectively. Each SBU is displayed as a circle. The size of the circles represents the market size. Market share is shown by using the circle as a pie chart and the direction and the movement of the SBUs in the future is shown by an arrow.

The GE/McKinsey matrix was designed as an extension of the BCG growth-share matrix (Henderson, 1970). The GE/McKinsey matrix has nine cells in contrast to the BCG Matrix that has only four and enables more detailed analyses. Some limitations of this matrix are that it is too complicated and too static, and it neglects the interactions with the environment and among SBUs.

cross-functional team

C. Anthony Di Benedetto

One of the most fundamental characteristics of new-product development is that the development is done by cross-functional teams. The activities that must be done for new-product success require skill in marketing, forecasting (see NEW-PRODUCT FORECASTING), research and development or engineering (see RESEARCH & DEVELOPMENT), production and manufacturing, operations, PRODUCT DESIGN, and these are among the functional areas within the firm that comprise the cross-functional team. Having a dedicated, empowered cross-functional team, and an effective team leader, is one way of accelerating the product's time to market (Gupta and Souder, 1998).

The teams, by definition, include individuals with different backgrounds and training, and this can cause trouble. Marketing people may fail to communicate effectively with R&D people, and vice versa (Souder, 1988). Different team members will have conflicting measures of success, or different expectations in terms of completion times. In some cases, individuals from different functional areas will be suspicious of or even dislike one another. Effective team management means managing the interfaces between the functional areas, and identifying and managing the frictions. Good managers know that a little conflict can be healthy, as it can lead to critical questions being raised internally and, possibly, some new solutions being identified. Nevertheless, it is important that conflicts among team members be properly managed. Forcing a solution, or seeking a superficial solution, is seen as less conducive to a positive environment for new-product development, while reaching an acceptable compromise or collaborative problem solving is preferable (Gobeli, Koenig, and Bechinger, 1998; Dyer and Song, 1998).

Cross-functional team management becomes substantially more complicated when the team has representatives from around the world. Firms are increasingly taking a global perspective to new-product development, tapping into knowledge and expertise that may reside in distant subsidiaries, and facing the challenges of managing global new-product teams. The barriers to overcome are many. Not all participants may be equally comfortable in the language used for team meetings; the meetings themselves are rarely in person but usually carried out electronically; and there are time zone differences to contend with. Cultural differences also exist, of course, which create more communication difficulties, but which may also lead to more creativity, multicultural synergies, and better problem solving (Song and Parry, 1997; Smith and Blanck, 2002; Sivakumar and Nakata, 2003).

virtual teams

Richard Blackburn

Virtual Teams have been defined in as many ways as there are those who write about them. McShane and Von Glinow (2008) define *virtual teams* as “Teams whose members operate across space, time, and organizational boundaries, and who are linked through information and communication technologies (ICT) to achieve organizational goals” (p. 291). Virtual teams are also referred to as *distributed or geographically dispersed teams*, but whatever the terminology, such a collection of individuals is in contrast to collocated teams, all of whose members work in the same place and communicate face-to-face. The relatively widespread popularity of virtual teams comes in response to new demands in the organizational environment for the more flexible use of highly valued knowledge workers who must respond more quickly to competitive demands without incurring the costs and delays necessary to get distant individuals in one place at one time (see also ORGANIZING FOR INNOVATION).

An important distinction that should be made is between a virtual group and a virtual team. Virtual group members need not interact to complete their group task. Sales people who interact virtually with a sales manager can successfully accomplish their sales task without much interaction among group members. Virtual teams do require substantial levels of member interaction to be successful. A virtual new-product development team reflects a situation where substantive member interactions are important for team success. The effectiveness of virtual teams is influenced by many of the same factors as those that influence collocated teams. Thus, when putting such a team together, a manager must consider the team's task, size and composition, processes, and organizational culture. Concerns specific to virtual teams include type and availability of ICT and the levels of member and leader training in operating in the virtual environment (see also CROSS-FUNCTIONAL TEAM).

Tasks that are relatively straightforward and structured tend to be more appropriate for virtual teams than tasks that are amorphous

and/or complex. While interdependence among team members is a given in virtual teams, attempting to manage substantial interactions with ICT is difficult. This also suggests that smaller teams composed of members with both cross-cultural sensitivity and skills to manage ICT will have a greater probability of being successful. These latter requirements often mean that certain training opportunities for would-be virtual team members and leaders will be beneficial. The best collocated team members may not make good virtual team members without specialized training.

An organization that wishes to organize itself around collaborative work units must insure that its systems and culture are supportive of these activities. Human resources systems like selection, training, compensation, and performance evaluation must be designed to enhance and reinforce the skills necessary to be a good virtual team member/leader. Additionally, the organizational values that undergird a firm's culture must support teamwork and multiple team membership for virtual teams to be successful.

Finally, processes in virtual teams differ somewhat from those found in collocated teams. All teams go through a developmental process beginning with a forming stage during which members meet and learn about each other. Occasionally, teams must work through a series of conflicts concerning the roles of various members and the procedures that the team will follow. This storming stage (hopefully) allows for the team to arrive at an agreement on how they intend to operate, and the norms that will guide these operations. Norm agreement and resolution of conflicts enables the team to begin performing at beneficial levels. In collocated teams, these stages tend to occur relatively quickly. Given the nature of the ICT, this process often can take more time with virtual teams. To move this developmental process along, virtual teams may meet together initially for a short time so that many of these issues can be resolved face-to-face. Once trust, norms, and cohesiveness are established with this early face-to-face encounter, it is much easier to maintain these processes in the virtual environment.

takeoff

Christophe Van den Bulte

DEFINITION

In the realm of innovation and new-product marketing, takeoff is the first marked increase in sales. It corresponds to the transition between the introduction and growth stages of the PRODUCT LIFE CYCLE, and to the kink in the hockey-stick pattern of new-product or market sales. When the sales evolution of the product experiences multiple growth spurts, then the concept of takeoff is often limited to the first such spurt.

RELEVANCE

Takeoff is of great importance to companies. Since sales and hence cash inflow dramatically increase after takeoff, knowing how long it will take for a new product to take off is very valuable to companies concerned about managing scarce financial resources. Knowing when takeoff will occur is also important for capacity planning in manufacturing, logistics, marketing communications (including sales force), and after-sales service. Given these cash-flow implications, knowing the likely time of takeoff is valuable to investors, too, and research has indeed documented abnormally high stock price returns in the year prior to takeoff (Markovitch and Golder, 2008). Having some consensus within the company of when a new product is likely to take off also gives business development and marketing managers the benefit of the doubt in the early stages of new-product commercialization, and prevents top management from “pulling the plug” and withdrawing the product (or market development investments) prematurely. Time to takeoff has also gained some popularity among marketing academics as a measure of diffusion speed, at least in the early stages of the new-product diffusion process (*see* DIFFUSION OF INNOVATION).

MEASUREMENT

The concept of takeoff has proved very hard to translate into a clear operational measure, and no consensus has emerged. Agarwal and Bayus (2002) and Golder and Tellis (1997), for

instance, both measure takeoff as the first year in which a product's relative growth rate crosses a particular threshold value, but determine that threshold differently, with the former using a fixed value and the latter using a sliding scale rule. Tellis, Stremersch, and Yin (2003) also use a growth-rate threshold approach, but with a different sliding rule. Chandrasekaran and Tellis (2008) simply define takeoff as the year in which the market penetration reaches 2% of the population, whereas Garber *et al.* (2004) use 16% penetration as their criterion. Such inconsistencies across studies limit the ability to generate cumulative evidence and insights one can be confident about.

FINDINGS

As new-product diffusion research has long documented, truly novel product categories often exhibit a pronounced S-shaped diffusion curve (*see* TECHNOLOGY S-CURVE; BASS MODEL), implying the presence of a takeoff taking place quite some time after the first product was introduced. Analyzing US sales data for 30 product categories, Agarwal and Bayus (2002) found that takeoff occurred on average 14 years after launch. They also found evidence that it tended to occur sooner over time, with the average time to takeoff decreasing from almost 19 years for products launched before World War II (WW II) to 10 years for those launched after WW II. Golder and Tellis (1997), using a different metric of takeoff, reported that time to takeoff for 31 consumer durables in the United States ranged from 2 to 60 years, with an average of 12 years (18 years before WW II and 6 after WW II). Analyzing the time to takeoff of 16 new consumer durables across 31 countries, Chandrasekaran and Tellis (2008) reported a steady and almost perfectly linear shortening of the time to takeoff from about 14 years for products introduced around 1915 to about four years for those introduced around 1995. Both these long periods to takeoff and the shortening over time are consistent with new-product diffusion research taking into account the entire diffusion process rather than only its earliest phase (Van den Bulte, 2000; Van den Bulte and Stremersch, 2004).

Once one moves beyond average duration and acceleration and considers likely causes, consensus disappears. For instance, there is only weak and mixed evidence on whether takeoff occurs more quickly in countries that are wealthier. There is also disagreement about what specific features of national culture, if any, are associated with fast versus slow takeoff. Several reasons may operate for these weak and inconsistent findings: the lack of strong genuine effects, inconsistencies in how the studies were designed and takeoff was operationalized, and low statistical power. All three reasons may also explain why studies on new-product diffusion taking into account the entire diffusion process have led to more consistent findings (Talukdar, Sudhir, and Ainslie, 2002; Van den Bulte and Stremersch, 2004).

Of particular relevance to managers is the question how price drives time to takeoff. Conventional wisdom and the early study by Golder and Tellis (1997) suggest that price declines are likely to trigger takeoff, with every 1% decrease in price leading to a 4.2% increase in the probability of takeoff. More recent research, however, casts doubt on this explanation. Specifically, Agarwal and Bayus (2002) and Bayus, Kang, and Agarwal (2007) have presented results in which the effect of price on the time of takeoff vanishes once one controls for the entry of new competitors. This suggests that it need not be price itself but the presence of increased competition – which happens to trigger price erosion – that makes takeoff more likely to happen.

One unresolved question, then, is how and why firm entry has an effect on takeoff time if it is not through price erosion. As Agarwal and Bayus (2002) note, increased competition is likely to lead to significant improvement in product quality, and that may very well be the factor triggering takeoff. Other intermediate mechanisms may be the legitimization of the industry and product category (as when IBM entered the personal computer market in 1981) and the improvement of the distribution infrastructure since intermediaries are more likely to invest in supporting a new product or technology when

more sources of supply become available. More research on how supply-side factors, especially those that can be influenced by managers, affect takeoff would be useful.

product positioning

David Reibstein

INTRODUCTION

Firms need to determine how they want their products positioned in the minds of their targeted customers. This means they should determine on what dimensions and where on these dimensions the product should be perceived relative to competition. The actual product position depends on how the customers actually view the firms' offerings on the dimensions of relevance to them. Perceptions of offerings are formed whether a company wants it or not and whether the firm is proactive in trying to shape the perceptions or not.

THE ROLE OF THE MARKETING MIX IN PRODUCT POSITIONING

Advertising and other communications efforts are to first make prospective customers aware of the product/service and then secondarily to help form the customers' perceptions of the product. But, communications is not the only element used to form the positioning of the product offering.

For example, one of Toyota's brands is the Prius. It is targeted at the environmentally concerned consumer. In 2009, it is probably viewed as the most fuel-efficient automobile in the market, as it was one of the first hybrid cars introduced. It gained this positioning not simply through advertising. First, because it was the first hybrid introduced into the market, fuel efficiency was closely associated with the brand. So, time to market plays a role in positioning of a product. The firm *first to market* with a particular feature is often viewed most closely associated with that dimension (*see also* FIRST-MOVER ADVANTAGE).

Obviously, *the product*, or overall offering, plays a significant role in the resulting positioning. The fact that the Prius is a hybrid and gets good mileage per gallon of gasoline contributes significantly to the positioning of the brand as being fuel efficient. In this case, it is made easier, because there are objective measures, posted online and in the automobile

dealers' showrooms, displaying the miles per gallon (mpg) of each model. More often than not, the critical dimensions are not objective and the task of positioning is more challenging. For example, Porsche wants to be positioned as sporty and Lexus luxurious and comfortable. Each of these has tried to achieve these positions and perceptions in customers' minds, by their product design (*see* PRODUCT DESIGN).

But, often, the product itself is not sufficient. Firms try to shape the customers' perceptions prior to the customer actually experiencing the product through their *communications* efforts. The Prius received considerable attention and notoriety around the fuel-efficient dimension because of the considerable public relations coverage they received. This has been coupled with an aggressive advertising campaign to support the continuing perceptions that the Prius is excellent in terms of fuel efficiency.

Similarly, the *distribution channel* with the showrooms, the signage at the showrooms, the sales people, and so on, all emphasize the fuel efficiency of the car. Where the product is distributed and how it is represented by the channel all contribute to the positioning.

The last element of the marketing mix is *price*. Prius charges a premium price. They justify this by the savings the customers will experience with the fuel efficiency. As such, even the price helps reinforce the perceptions in the marketplace.

THE ROLE OF COMPETITION IN PRODUCT POSITIONING

The Prius is no longer the most fuel-efficient car on the market. That said, the Prius still remains solidly in the *position* of being dominant in terms of fuel efficiency. The point is that while Prius competitors have technologically leapfrogged the Prius in terms of fuel efficiency, they have not in terms of positioning. The point is that positions are perceptual and these perceptions are not just shaped by the product alone. The critical point is that customers buy on the basis of their perceptions of the choices they have. The second point is that positions are also relative. What we consider as "long" battery life for a computer today is far different than what we did consider as a dominant position only a few years ago, and

2 product positioning

what we will consider as such a decade from now. For a laptop to have a battery life of four hours in the mid-2000s was considered excellent, but today is on the low range. By the year 2015, it will not be surprising to find that average PC battery life will be well in excess of 24 hours and beyond. Hence, a firm's position is temporal and will be shaped by competitive activity.

General Motors will be offering their new Volt brand in 2010 which will have a fuel efficiency of 230 mpg, well in excess of the Prius' 40–51 mpg. With this introduction, without a significant change by Toyota, the Prius will no longer be perceived as the dominant fuel-efficient offering.

SELECTING A POSITION

A firm needs to know where it should be positioned. This starts with (i) a selection of a

target market, (ii) the identification of the critical dimensions the target uses for selecting which product it will choose, (iii) an understanding of the ideal levels the target desires on those dimensions, often referred to as an *ideal point*, and (iv) working through the use of the entire marketing mix to gain targeted customer perceptions closer to this ideal than any of the other choices on the market.

open source

Nikolaus Franke

In *legal* terms, “open source” means that anyone who wishes can use, modify, and improve the product, and redistribute it in modified or unmodified versions to others. This term is most commonly used in the context of software to denote systems or applications (e.g., Linux, Apache, or Firefox) where the source code can be accessed by any user, and which are distributed under specific copyright licenses that ensure the above-mentioned privileges (for a definition, see <http://opensource.org/docs/osd>). However, the principle of not asserting private intellectual property claims (*see* INTELLECTUAL PROPERTY RIGHTS) can be applied to other products as well.

In *economic* terms, open-source software is a public good. Because of its modular character (*see* PRODUCT MODULARITY), it is often developed by virtual-user networks or communities in a distributed and collaborative manner. Users are not paid in exchange for their contributions, and the software can be downloaded freely by anyone. Prior to the success of open-source software, many held a strong belief that such a regime of systematic “free-riding” would bring about insufficient incentives to innovate. However, in many cases, open-source software is highly innovative and successful, and its importance is still growing. More than 100 000 open-source projects are currently underway, and estimates of the value created by such projects run into billions of dollars. Open-source software can be considered one of the strongest arguments for the importance of the mega trend toward OPEN INNOVATION. Its success has been explained by the fact that developers themselves decide which problem they work – the assignment thus is not made by a central authority. Often, the specific problem is far ahead of current trends, and the user urgently needs a solution himself/herself – thus many contributions can be referred to as lead-user innovations (*see* LEAD USERS). Second, a potentially large number of users contribute to open-source projects – far more than in proprietary software production. The advantage is summarized in what

Raymond (1999) termed *Linus’ Law*: “Given enough eyeballs, all bugs are shallow.”

All this raises the question of user *motives* for contributing to this public good. Research has found that both intrinsic (e.g., fun, enjoyment, altruism) and extrinsic motives (e.g., learning, reputation building, social norms) explain why users participate and freely reveal their proprietary knowledge.

A great deal of research has been devoted to the question of how open-source projects are organized and governed. Compared to hierarchical systems such as companies, there is a relatively low level of coordination activity, and the most important management tool is a simple mailing list. Contribution activities are often highly concentrated among a small number of core people, but the projects involve other important roles as well (such as testing and assistance). This loose form of governance sometimes leads to a “forking” of the project, that is, two (or more) versions of the software are developed in parallel.

For companies, the open-source phenomenon can present a challenge as well as a business opportunity. First, the provision of a free, high-quality public good threatens the existence of companies that operate by producing and selling similar (proprietary) products. On the other hand, there are many potential business models that would allow companies to profit from open-source software (and other “open-source” products). One possible model would be to use the software for one’s own business purposes, while another would be to market complementary products and services. Companies can also adopt the principles of open-source projects and outsource certain elements of their own new-product development and marketing activities to self-organized (or loosely governed) communities of users. Such activities might include idea, concept and prototype generation, RESEARCH & DEVELOPMENT, CONCEPT TESTING, and PRODUCT TESTING, customer support and help-line activities, and so forth.

technology S-curve

Ashish Sood

THE TECHNOLOGICAL S-CURVE

The technological S-curve describes the phenomenon of technological evolution and suggests that technologies evolve through an initial period of slow growth, followed by one of fast growth culminating in a plateau (Foster, 1986; Sahal, 1981; Utterback, 1994). When plotted against time, the performance resembles an S-curve (see Figure 1).

The field does not enjoy a single, strong, and unified theory of technological evolution. However, an emerging, and probably the most compelling explanation, revolves around the dynamics of firms and researchers as the technology evolves through the three major stages of the S-curve of technological evolution: introduction, growth, and maturity (*see also* PRODUCT LIFE CYCLE).

INTRODUCTION STAGE

A new technological platform (Sood and Tellis, 2005) initially makes slow progress in performance during this early phase of its product life cycle. Two reasons may account for this situation. First, the technology is not well known and may not attract the attention of researchers. Second, certain basic but important bottlenecks need to be overcome before any new technological platform can be translated into practical and meaningful improvements in product performance.

GROWTH STAGE

With continued research, the technological platform crosses a threshold after which it makes rapid progress. Three factors may account for this change—the emergence of a dominant standard (Utterback, 1974); product characteristics and consumer preferences coalesce on the new standard and/or larger number of researchers attracted by the publicity of the standardization; and increase in sales of products that translates into greater support for research.

Figure 1 Technological evolution: technological S-curve.

MATURITY STAGE

After a period of rapid improvement in performance, prior research suggests that the new technology reaches a period of maturity when progress occurs very slowly or reaches a ceiling (Foster, 1986; Brown, 1992; Utterback, 1994; Chandy and Tellis, 2000) for various reasons—innate characteristics of a technology; changing focus of innovation as markets saturate; fears of obsolescence or cannibalization; and limits of scale or system complexity.

RECENT EMPIRICAL FINDINGS

Recent empirical findings on the phenomenon question the support for the theory (Sood and Tellis, 2004, 2005; James and Sood, 2005). These authors plotted the performance of 23 technologies over time from six markets over more than 100 years: four each in desktop printing, display monitors and analgesics, and three each in desktop memory and data transfer, and five in external lighting. In a majority of the technologies, they found long periods of static performance interspersed with abrupt jumps in performance. This suggests that the path of technological evolution is neither smooth nor does it resemble an S-curve.

If a technology does not evolve in the shape of an S-curve, an analyst expecting such a path might conclude from periods of static performance that the technology has matured at the upper asymptote, when indeed it has not. The risk is in abandoning the old technology prematurely.

product modularity

Tucker J. Marion

DEFINITIONS

Modularization is an approach to organize complex designs and process operations more efficiently by decomposing complex systems into simpler subsystems (Jose and Tollenaere, 2005). These subsystems may be a common engine-transaxle combination used in a variety of automobiles. For example, Honda shares an engine and transaxle combination among a variety of vehicle lines including the compact Civic, midsize Accord, and CR-V sport utility (Meyer, 2007). What makes this possible is well-defined product architecture and component interfaces (*see also* PRODUCT DESIGN).

Product architecture is the method by which product function ties to physical components. Defining product architecture is a key element in the engineering design of modular products, and should be performed during system-level design early in the new-product development process (Ulrich and Eppinger, 2004). Ulrich (1995) defines product architecture as (i) the arrangement of *functional elements*; (ii) the mapping from *functional elements* to *physical components*; and (iii) the specification of the *interfaces* among interacting physical components. The functional elements are high-level product features and actions. For example, a functional element in a door handle is to *secure door*. The corresponding physical component that will secure the door is a *latch*. The latch will need to have well-defined connection points, or interfaces. In this example, thought and specification will need to go into the methods by which the latch connects to the door handle, locking mechanism, and door jamb.

To accomplish the arrangement of functional elements into building blocks and define their interfaces, several methods have been proposed, including the development of functional diagrams (Pahl and Beitz, 1996). The function diagram or function structure is a representation of an electromechanical system consisting of inputs to the system, outputs from the system, and internal subfunctions within the system, which can then be used to identify pertinent interfaces within the system (Pahl and Beitz,

1996). Physical components tie to functions and other components in the system. A functional diagram of the door handle example is shown in Figure 1 (Marion *et al.*, 2006).

As shown in Figure 1, interfaces are interacting components (i.e., a door handle/knob connected to a latch) with geometric connections. An interface specification defines the protocol for the primary interactions across the component interfaces (Ulrich, 1995). For example, if one were designing a door handle and locking system, they might want to offer the option of different door handles/knobs to the consumer. This requires a common interface between the components. Figure 2 illustrates a common door handle/knob and shaft interface.

Standard interfaces are common in industry; examples include USB connections and automobile tire hubs. A product is termed *modular* if there is a one-to-one or many-to-one mapping of functional elements to physical components (Ulrich, 1995). In the door handle example, to actuate the system, one must turn the door handle/knob. The latch performs the locking function. This is an example of a modular design via one-to-one mapping of function to component. Modular subsystems and design are applicable to other areas such as software development. For example, the Mach kernel in Apple's OS X operating system is a software subsystem that is ported to the iPhone, iPod Touch, and Mac personal-computer platforms (Silbershatz *et al.*, 2004).

BENEFITS

Because modular designs have a beneficial ratio of functions to components (one-to-one in the extreme), components of the product can be modified or replaced without changing other components in the design (Ulrich, 1995). For example, engines can be upgraded over time in the Honda example. This can focus R&D resources on localized components or subsystems that need change, thereby reducing the need to modify the entire product. Modular products have well-defined interfaces, so they have the inherent property that they can be manufactured in a flexible manner. Again using the Honda case, vehicle assembly plants can produce a wide variety of different models with

Figure 1 Example of a functional diagram of a door handle/knob noting the functions, components, and interfaces.

Figure 2 Interface design of a door handle/knob and shaft; note the common interface and unique handle/knob.

modularity, reducing changeover cost and maximizing economies of scale (see also PRODUCT-LINE STRATEGIES).

Product modularity is closely related to another engineering paradigm: the PRODUCT PLATFORMS. Product platforms involve the use of common components and subsystems throughout a product line (Meyer and Lehnerd, 1997). Product modularity at the component and system levels can foster subsystem and component reuse.

In summation, designing a modular product has many benefits from manufacturing flexibility to reduced R&D expenses during PRODUCT DESIGN. Well-defined product architecture and interfaces can foster the development of product platforms, which can help a firm easily introduce successive revenue-generating variants. During up-front product design, intelligently designing modularity into components and subsystems is an essential step toward development of a successful product line.

prototype

Richard Blackburn

Prototype (prototyping) refers to an approximation or model (in any appropriate medium) of an idea or concept along one or more dimensions of interest. Prototypes can be produced at any point in any development process. Michael Schrage (2000b) argues that prototypes can serve as valuable “shared spaces” within which a new-product development (NPD) team might enhance the efforts of its development process. While concept specifications might describe the team’s “wish list” (see PRODUCT SPECIFICATIONS), prototypes make those wishes “real.” Prototypes might suggest where the team’s wishes were unrealistic, but they can also indicate where the team’s wishes might not have been imaginative enough (Schrage, 2000b, p. 71).

Prototypes come in a variety of flavors—as simple as a diagram on the back of a napkin or as complex as a fully functional representation of a product one step removed from actual production.

More specifically, NPD teams can produce two-dimensional drawings or computer-generated plans, three-dimensional “form studies” (built from foam, polymer, or constructed “virtually” with computer-assisted design systems), functional prototypes showing how a product is supposed to work but without any “packaging,” user test models that incorporate function and packaging, and system prototypes that illustrate how manufacturing, packaging, and distribution systems must be aligned to incorporate the new product (see also PRODUCT TESTING).

As the team moves from simple to more-complex prototypes, the cost of doing so can increase substantially. However, recent advances in rapid prototyping provide less-expensive methods for building more-complex models.

Judicial use of prototypes can assist the NPD team in a number of ways. For instance, *prototypes can help the team learn* if the proposed concept works as anticipated, and/or if the concept meets the customer’s needs or wants. *Prototypes can facilitate communication* among

NPD team members and among other key stakeholders both inside and outside the team. A discussion around the tangible rendering of any concept will likely be more useful than a discussion in which ideas remain as evanescent dreams in team members’ minds. *Prototypes can assist in the integration of information* about the fit of components in a larger concept as well as the extent to which cross-functional demands are being met in a particular concept. Finally, *prototypes can function as milestones*, indicating how far the NPD team has progressed toward a development goal and/or the extent to which the team has proven the value/worth of the proposed concept.

Interestingly, Schrage suggests that just as organizations may have quality or safety cultures, they can also have a “prototyping culture,” which he contrasts with a “specification culture.” Firms with specification cultures often tend to innovate at the margins of existing products. Those with prototyping cultures are more likely to produce substantive innovations with unique offerings. From Schrage’s perspective, strong prototyping cultures produce truly innovative products (see RADICAL INNOVATION; INNOVATION TYPOLOGIES).

If high-quality prototypes are a function of a company’s culture and its willingness and ability to innovate, what are some of the characteristics of such cultures? In prototyping cultures (versus specification cultures), the prototypical models are

- referred to as *prototypes* and are *designed* rather than being called *mock-ups* that are *assembled*;
- used to explore opportunities and provide feedback rather than manage risks and publicize products;
- ephemeral and dynamic (virtual) rather than permanent and static (actual);
- appear early and often at various steps in the NPD process rather than infrequently and late in that process;
- not “frozen” until late in the process rather than frozen whenever they appear in the process;
- community property open to public viewing at any time rather than being “owned” by

2 prototype

a particular function/unit with controlled viewing; and

- developed with frequent external contribution/collaboration rather than developed solely with contributions from the NPD team (Schrage, 1993).

In sum, if the concept of quality is approximately a function of the quality of prototypes produced multiplied by the number of prototypes produced, then to build better concepts NPD teams must learn to build better prototypes and to build them faster.

product specifications

Robert W. Veryzer

This entry encompasses Product Specifications as the culmination of an evolution from determining product Requirements to the development of Objectives that provide guidance for detailed descriptions for how a product is to be constructed. Although terminology varies somewhat across industries and firms, with “product requirements,” “engineering characteristics,” “specifications,” or “technical specifications” being used in some instances (Ulrich and Eppinger, 2008), the steps that result in product specifications are essentially the same. In effect, “product specifications” are the outcome of a process that leads to a precise blueprint for (making) a particular product (*see* PRODUCT DESIGN).

Requirements (e.g., “easy to operate,” “large storage capacity,” “light weight”) are statements of what has been determined through study and exploration of user/customer needs (*see* VOICE OF THE CUSTOMER), and relevant market or firm considerations for a new product (Veryzer, 2003). These may come from knowledge of the marketplace, interviews with LEAD USERS or existing or potential customers, input from distribution channel members (e.g., dealers or retailers), research or product use tests, and so on. Requirements may also encompass such aspects of a product being designed as the physical product structure, operating systems, interactions among or dependencies with other products, and others, to the extent that these are indicated through investigation of one or more of the input sources (e.g., lead users, dealer network, and product-use test participants).

After a development team (*see* CROSS-FUNCTIONAL TEAM) has devoted sufficient effort to identifying and understanding user/customer needs (*see* VALUE PROPOSITION), and then identified the *requirements* for a product being designed, the requirements are formulated into descriptions of particular aspects of the product. Although various terms may be used, these descriptions are essentially *objectives* that indicate the formal goals for various aspects

of a product such as performance capabilities and task times. Either formally or implicitly, the determination of objectives involves judgments concerning trade-offs among different product characteristics (e.g., speed vs. weight).

Objectives, in turn, are translated into precise targets, or *product specifications*. Product specifications detail in precise, measurable ways how a product is to be made. Product specifications – which may range over various dimensions of a product: physical elements and materials, structure or architecture, control or operating systems, and so on – consist of metrics or measures relevant to a particular product dimension, and indicate the desired level (or value) that is to be achieved for each measure. In the translation of objectives to specifications, the capturing (measuring) of more subjective needs, though challenging, should be done in as concrete a way as possible (for example, an index or assessment of customer satisfaction).

The process (*see* THE STAGE-GATE IDEA TO LAUNCH SYSTEM) for determining product specifications may vary depending on the type of product being designed (for example, consumer durables vs. electronics products vs. computer software). However, the following considerations usually apply:

- The general sequence for determining product specifications moves from requirements to objectives to product specifications.
- Each class or type of product may have its own standards and conventions.
- Marketing research can play an important role in the identification and validation of requirements.
- Objectives should recognize resource and time constraints.
- For certain types of products (for example, software and electronics), there may be established, very particular formats for requirements and product specifications.
- With advances in electronic and digital technologies, there is now often considerable latitude in specifications as concerns product configuration (in general, electronics products and software tend to be less constrained than products based on mechanics).

process innovation

Henry Robben

Process innovations typically change the way in which suppliers create or distribute products or services (Tushman and Nadler, 1986). In essence, the product or service remains the same, in terms of its appearance or the benefits it provides. It is the way of their production that changes. Typically, most of such changes are what we call *incremental* or *synthetic* changes. They lead to an improvement in production costs or product quality. As such, they improve the efficiency of current production processes. We also discern radical or discontinuous process innovations (see RADICAL INNOVATION; INNOVATION TYPOLOGIES). Such innovations significantly alter the way in which we produce products or services. For those innovations to occur, we need different approaches in management and manufacturing, and, likely, new skills sets as well.

Process innovation is especially important during the growth phase of the product life cycle, when competition revolves around price, quality, and segmentation (see PRODUCT LIFE CYCLE). A consequence of this may be the opening up of a market for a larger audience and product enhancement. As such, process innovation may play a strategic role for the organization.

The performance of a new-product development project tends to be determined by a few high-level, critical processes that need management's focused attention and efforts. To make it work well, all participants should understand the whole process and be motivated; otherwise, it cannot be effectively executed or improved. It is necessary to have a thorough understanding of the business and of the company's innovation management process to be able to improve, reengineer, or innovate any process within the organization.

The task of all managers is to improve their operations. There are several approaches to trigger off process innovation or improvement. We can distinguish the following triggers (Trott, 2008):

1. *Gap analysis*: Are there differences in expectations among customers, suppliers, and management?
2. *Quality circles and process improvement teams*: On the basis of their individual expertise, members of such groups suggest ways to innovate or improve current processes. They may work on a voluntary basis or be a systematic part of the innovation and new-product development processes.
3. *Total quality management (TQM)*: This is a system that continuously integrates quality development, quality maintenance, and quality improvement. It is an integral approach, requiring efforts from multiple departments, aimed at creating customer satisfaction at the most economical level.
4. *Quality function deployment (QFD)*: QFD is a concurrent methodology that systematically relates customer requirements to marketing, engineering, and operations requirements (see QUALITY FUNCTION DEPLOYMENT (QFD)).
5. *The ISO 9000 approach*: This is an internationally used system that checks whether an organization adheres to specific requirements.
6. *The European Foundation for Quality Management (EFQM) excellence model*: According to this system, a number of enablers lead to performance through managing and controlling input and output processes. It is a self-assessed procedure.
7. *Six sigma*: This is a methodology for designing complex systems, using an approach that defines, measure, analyzes, improves, and controls the extent to which results meet requirements. It should lead to a reduction of manufacturing or service problems in the parts-per-million range.

Process innovation measures and modifies organizational dynamics by optimizing the activities required to reach end goals or objectives (Tighe and Kraemer, 1996). A procedure to arrive at process innovation may be the following:

1. *Process mapping*: This phase shows how a process proceeds in time and the agents involved in the process. It delivers a flow

2 process innovation

- of how the agents influence and direct the process, and with what frequency.
2. *The ist-situation*: It is important to understand how the process currently works, and why. We need to evaluate what drives and maintains the current process.
 3. *Benchmarking, best practices, next practices*: Research should show which companies or business units have an exemplary performance, either within or outside the industry. Here, we should emphasize that reaching a benchmark may not be sufficient in creating radical process innovation. Rather, we should look for next practices.
 4. *The soll-situation*: Here, we need to have a good understanding of the desired situation. Why do we want or need to be there? This objective should be consistent with or leading to the company's long-term objectives. Sometimes, we call this process *blueprinting*.

5. *Implementation*: Obviously, a process innovation needs implementation. Here, management and workers face continuous changes, pilot testing and working with early adopters, training them and the workers, and documenting the process.

product diversification

Ashish Sood

Product diversification is one of the four main marketing strategies defined by the Ansoff matrix, a tool that helps firms formulate their product and market growth strategy (Ansoff, 1957) (see Table 1) (see also GROWTH STRATEGIES).

In this growth strategy, a firm markets new products in new markets. Diversification is the most risky of the four growth strategies since it requires a firm to acquire new skills, new techniques, and new facilities. In contrast, the other three strategies require existing competencies of the firm. As a result, diversification often leads to substantial changes in the organizational structure, competencies, and resources of the firm (see also ORGANIZING FOR INNOVATION; CORE COMPETENCIES). Therefore, a firm should choose this option only after careful analyses of all opportunities.

TYPES OF DIVERSIFICATION

There are three types of product diversification: vertical, horizontal, and lateral (Ansoff, 1957). In vertical diversification, a firm introduces new products, which are related to current products, into new markets. Hence, the focus is on creating a portfolio of related businesses. In horizontal diversification, a firm develops or acquires new products that are different from its current products, but which may appeal to its current customers. Hence the focus is on gaining market share. In lateral diversification, a firm introduces new products that are different

from its current products into new markets. Hence the focus is on entering completely new markets with new products and is more radical than the first two types of diversification.

Firms may employ these three types of diversification on the basis of market growth conditions (Ramanujam and Varadarajan, 1989). For example, a firm may choose either vertical or horizontal diversification when market conditions allow firms fast growth opportunities. On the other hand, lateral diversification may become necessary when market conditions show declining overall demand. Similarly, a firm may choose lateral diversification to develop competencies in a new area of technology.

prediction markets

Thomas S. Gruca

INTRODUCTION

A prediction market is a market-based method for forecasting (*see* CONCEPT TESTING, NEW-PRODUCT FORECASTING, PRETEST MARKET MODELS). Prediction markets are used to generate a forecast regarding a specific future outcome such as the vote share in a political election, the opening weekend box office results for a new movie, or the winner of a contest (e.g., a World Cup final). Participants interact with each other by buying and selling financial instruments (i.e., futures contracts) whose ultimate value is determined by the outcome of the future event. The prices in a prediction market reveal the consensus forecast of the traders (Gruca, Berg, and Cipriano, 2005). In many applications, these forecasts have been highly accurate on an absolute basis and when compared to alternative forecasting methods. For example, the Iowa Electronic Market (IEM) has been forecasting the share of the popular vote for every presidential election since 1988. The mean absolute error of the forecasts for the 1988–2004 elections were 1.33% compared to 1.62% for the average public opinion poll. In 2008, the IEM was even better with a mean absolute error of 0.3% versus 1.2% for polls.

Over the past few years, the applications of market-based tools for forecasting have expanded in several important directions including new types of traders and different outcomes of interest. After reviewing the basic theory behind using markets as an information-gathering tool, the major advances in this area are discussed in approximate order of development.

THEORETICAL BACKGROUND

Prediction markets take advantage of a market's ability to distill disparate sources of public and private information into a single measure: price. Rational expectations theory suggests that price alone is a sufficient statistic for all information available to traders in a market. Consequently, through the mechanism of price, all traders in a

market (and any observers) can share the knowledge held by each and every trader (Sunder, 1995). In theory, markets should be an excellent method for aggregating information about future events and providing an accurate forecast.

Laboratory studies in experimental economics document the ability of markets (i) to disseminate information from informed traders to uninformed traders, and (ii) to aggregate information across traders. These laboratory results suggest that markets are capable of the information-processing tasks required by rational expectations theory (Sunder, 1995). The final question to be addressed is whether actual prediction markets could realize their potential to provide accurate forecasts of future events.

INITIAL (AND CONTINUING) SUCCESS

The first public prediction market was the Iowa Political Stock Market (now known as the Iowa Electronic Market or IEM) conducted to predict the vote shares of the two major candidates in the 1988 US presidential election. The market's election eve predictions of the popular vote shares were more accurate than those available from pre-election "trial heat" polls (Forsythe *et al.*, 1992).

One key finding from this market is that traders need not be a representative sample of voters in order for the market to provide accurate forecasts. In the 1988 market, the traders were primarily students and faculty at the University of Iowa. Even though these traders were clearly not a representative sample of voters, the prices in the markets predicted the election-day vote shares better than polls based on representative sample of voters.

A second key finding is that there is clear evidence that the average trader is biased (e.g., paying more for contracts associated with one's favored candidate) and prone to trading errors (e.g., creating risk-free arbitrage opportunities for other traders). Nevertheless, the IEM election markets have forecast the eventual outcomes (i.e., popular vote shares) with a higher degree of accuracy than the polls.

To explain how a market made up of biased, error-prone traders can produce accurate forecasts, Forsythe *et al.* (1992) proposed the "marginal trader hypothesis." Marginal traders

2 prediction markets

are able to put aside their personal preferences and trade according to their heads, not their hearts. They are usually very active traders who tend to be the ones setting prices in the market and they are less likely to make trading errors in favor of other participants. It is the price-setting actions of the marginal traders that move the prices of the contracts in prediction markets to correct levels.

INTERNAL PREDICTION MARKETS

A major advance in the application of prediction markets was to apply this method to the problem of forecasting the future sales of existing products. These markets, conducted by researchers from the California Institute of Technology and HP Laboratories, used selected managers from Hewlett-Packard as traders (Chen and Plott, 2001). The idea was to test whether a prediction market could successfully aggregate important business intelligence that is widely scattered throughout a large organization. The forecasts generated by contract prices in the prediction markets were generally more accurate than those produced by the firm's own official forecasts.

These results showed that prediction markets are useful in situations where the traders were relying mainly on private information. In an election prediction market conducted in the United States, there is often a great deal of public information (e.g., trial heat polls) upon which to base one's trades. In contrast, the traders in the HP markets were bringing private information to the market from many parts of the overall organization. Through trading, these varied sources of information were aggregated into contract prices that yielded a consensus forecast as well as a reflection of the degree of differences in opinions across the traders.

SECURITY DESIGN IN REAL MONEY PREDICTION MARKETS

The value of the securities being traded in a prediction market ultimately depends on the outcome of interest. How the outcome is related to prices in the prediction market is a key design choice. For example, consider a prediction market focused on the popular vote in a US presidential election. Such a market may involve

trading in three securities, one for each of the Democratic and Republican nominees and one for "All other candidates." One approach is to link the ultimate value of the security to the proportion of the total vote share for the corresponding candidate. At the end of the market, the total value of all three securities would be unity (\$1).

A second alternative is a "winner-take-all" payoff structure. In this design, the security associated with the candidate that obtains the largest share of the popular vote pays off \$1 and the other two securities payoff \$0. Using this latter payoff structure is also known as offering a set of Arrow-Debreu securities. This approach has been used to provide forecasts of continuous outcomes such as product sales (Chen and Plott, 2001) and movie box office receipts (Gruca, Berg, and Cipriano, 2005).

To provide traders with contracts to sell, many prediction markets follow the design of the IEM by using a "bundle" transaction. For example, consider a prediction market with three mutually exclusive and collectively exhaustive outcomes. The bundle contains one contract corresponding to each of the possible outcomes of the future event. Traders buy a bundle of contracts from the market at a fixed price. This price is the same value as holding a "winning" contract, usually \$1. Since one of the contracts will pay off while the others will become worthless, the expected value of a set of all contracts is \$1. This approach ensures all transaction prices are set by traders and that the supply of contracts is limited only by the funds available to the traders.

PLAY MONEY PREDICTION MARKETS

A prediction market uses a market mechanism to aggregate the information available to individual traders. Traders with superior information about the outcome of interest can benefit from trading with other participants who are less well informed. The key question is how to motivate traders with valuable information to participate in a prediction market.

One possible solution is to use real money incentives. However, depending on the application, a public prediction market using real money payoffs may be subject to laws regarding gambling, securities trading, sales promotions,

and election fraud prevention, among others. Such laws vary widely across jurisdictions (Hahn and Tetlock, 2006).

The Hollywood Stock Exchange (HSX) is an internet-based game. The goal of the game is to acquire fictitious “Hollywood dollars” (denoted H\$) through the trading of various securities tied to outcomes in the entertainment field including box office performance, awards shows, and so on. The most significant of these securities is the “Moviestock.” The value of a Moviestock is determined by the total US box office receipts (in millions of dollars) over the first four weekends after a film has achieved wide release (greater than 650 screens). For example, if traders (as a group) expect a movie to take in \$75 million during that time period, the price for the Movie stock will be H\$75.

A Moviestock is usually issued very early in the development of a movie and its value changes as the film moves from concept to finished product. The initial price of a Movie-stock is set by the HSX exchange. To avoid the influence of traders with inside information, trading is halted on Friday afternoon of the first weekend the movie is widely released in theaters. The Moviestock price is then reset by HSX to 2.9 times the first weekend’s box office receipts (in millions of dollars) on Monday when trading resumes (different multipliers are used for movies opening on different days). Such market interventions are possible since HSX uses play money.

Empirical studies of the accuracy of the predictions of HSX markets find a surprisingly high level of forecasting accuracy (Pennock *et al.*, 2000; Spann and Skiera, 2003) on an absolute basis and when compared to the predictions of individual forecasters. A recent study comparing the results of 19 real money (IEM) and play money (HSX) box office prediction markets found no significant differences in overall accuracy (Gruca, Berg, and Cipriano, 2008).

Traders in play money prediction markets such as HSX are motivated by considerations other than monetary gain. By using play money rather than real money payoffs, users of prediction markets may be able to avoid the legal challenges noted above. However, it should be noted that some studies comparing the relative accuracy of real money and play money

prediction markets find significant improvements when real money payoffs are used (Rosenbloom and Notz, 2005).

INTRODUCTION OF USER-FRIENDLY TRADING

Prediction markets usually use one of two ways to organize trading. Real money markets (and some play money markets) use a dual auction. Other markets use a “market maker,” which is described below. In a dual auction, traders can submit limit orders or market orders. Limit orders are offers to buy or sell at a specified price. These offers may or may not be accepted by other traders in the market. In contrast, market orders are executed immediately on the basis of previously posted limit orders.

The second major approach is to use some type of market maker system. The HSX market is one such example. In this type of market, buyers and sellers submit their orders to the market maker, which determines the prices using a predesigned set of rules. The advantage of this system over the double auction is a much lower barrier to entry for traders without experience (or training) in market trading.

There is at least one possible drawback to using a market maker system. Consider a trader who sees a favorable price in the HSX market and submits an offer to buy at the “current” price. The price observed by a trader is only a reflection of the last price at which trades took place. If there are a larger number of buy orders than sell orders placed within a short time period, the trader may end up paying much more than he or she expected once the market maker executes the set of concurrent buy and sell orders. This is a less important issue for securities like Moviestocks with a large range and a continuous outcome space. Such pricing uncertainty would be very problematic for prediction markets where the outcome range is narrow. For example, whether a contract is over- or undervalued may be a matter of a few cents in a prediction market forecasting popular vote shares of a very close election.

PREDICTION MARKETS OF EXTERNAL EXPERTS

In the wake of the intelligence failures surrounding the 9/11 attacks, the US

Department of Defense (DoD) undertook an extensive program of research on information systems to identify threats to national security. Managed through the Defense Advanced Research Projects Agency (DARPA), the FutureMap program was intended to develop market-based methods to provide accurate assessments of the likelihood of future events of interest to the DoD. Traders in these prediction markets would be independent experts with a variety of backgrounds. Ultimately, a description of a pilot study was incorrectly characterized in the media as a “terrorism market.” Subsequent political opposition to the program led to its cancellation in 2003 (Surowiecki, 2004).

Unfortunately, there have been few subsequent prediction markets that have attempted to aggregate information from a varied set of experts. This is an important issue, since some prediction markets that rely on self-selected traders from the general public generate very accurate forecasts (i.e., US election markets) while the predictions in other domains are much less satisfactory (i.e., forecasts of movie box office results). This is an important area for future research.

One exception is a series of prediction markets using different types of medical personnel, for example, physicians, school nurses, and public health officials to generate short-term forecasts (two weeks ahead) of the severity of local outbreaks of influenza (Polgreen, Nelson, and Neumann, 2007). While this application is promising and may be useful in other areas of public health, it is still unknown whether expert traders can consistently predict low-probability, high-impact events (e.g., an unexpected early call for elections).

PREFERENCE MARKETS

Building on the success of prediction markets, a group of researchers at Massachusetts Institute of Technology (MIT) developed a market-based method for measuring consumer preferences for product concepts, attributes or even levels of a product attribute (*see* CONCEPT TESTING). Like a prediction market, participants in a preference market buy and sell securities. These represent, for example, alternative product concepts.

Unlike prediction markets, however, there is no objective outcome that is used to determine payoffs to traders. Instead, the goal of the traders is to maximize the value of the portfolio of securities they hold at the end of a short trading session (usually about 15 minutes). The prices of the securities are determined by the traders’ personal preferences for the various concepts and the traders’ assessment of others’ preferences for the concepts. Traders are rewarded based on the value of their portfolio relative to other traders. Incentives for MBA students participating in these markets have included gift certificates or small amounts of cash (\$50).

To test the external validity of the results of the preferences, the researchers compared the market prices for a set of product attributes with two sets of preference measurements from traditional marketing research methods. The correlations were higher for the markets of MBA student traders (0.802 and 0.885) compared to those from markets where industry managers were traders (0.714 and 0.769). This suggests that preference markets can be useful in measuring preferences for a product concept, an attribute, or the level of an attribute (Dahan, Soukhoroukova, and Spann, 2009).

There are some potential limitations to using preference markets instead of traditional approaches such as conjoint analysis. The first is the lack of actionable segmentation of the market. A key advantage to conjoint analysis is the ability to segment the overall market with respect to differences in preferences for various attributes and levels of attributes. By design, the prices in a preference market can only provide an estimate of the consensus of the traders’ preferences.

The second issue is that of trader selection. In public prediction markets such as the IEM election markets, traders are self-selected. Those who believe they possess superior information can choose to participate at the risk of their own funds. As noted above, the pools of traders need not be representative of the voting population for the market to produce an accurate forecast. In contrast, a preference market needs to confine its traders to a representative sample of consumers or a set of traders with a sufficient level of insight into the target consumers. In the case of using a representative sample of consumers, there is

no real advantage for the researcher in terms of sampling costs and effort between using a preference market or conducting a conjoint study. The results above show that even managers with industry experience do not necessarily have insights into the preferences of their consumers. This begs the question of how to recruit, screen, and motivate traders with a sufficient level of knowledge about the preferences of consumers who are not like themselves.

A final challenge for preference markets is to measure the relative importance of price versus other attributes. Traders in preference markets are not really making trade-off decisions as do respondents in a conjoint analysis study. Being able to put a dollar value on different levels of an attribute is one of the most important outputs of any conjoint analysis study.

A major advantage of preference markets over traditional methods of preference measurement is scalability and engagement of participants. Recently developed preference markets can quickly identify the clear winners and losers from a very high number of product concepts or attributes. Furthermore, traders are very positive about the experience.

NEW-PRODUCT IDEA MARKETS

Preference markets evaluate the relative attractiveness of different product concepts using consumers as traders. In new-product idea markets, the goal is to elicit and evaluate alternative new-product ideas using a company's employees as traders. As an idea-generating method, an Internet-based market has a number of important advantages. By using the Internet as the platform for interaction, an idea market can involve a large number of employees who are widely scattered across the globe. Since trading takes place over a number of days (or even weeks), participants can see ideas developed by others and create new options that improve upon earlier ideas. The prices generated by a market mechanism provide a continuous measure of the relative attractiveness of various proposed ideas.

An application of idea markets with one division of General Electric (GE) found that more ideas were generated and more employees participated than is typical for an idea generation

exercise. There was a comparatively low correlation (0.43) between the market's ranking of an idea (based on the price of the associated security) and the average evaluation of the division's leadership team (LaComb, Barnett, and Pan, 2007). A subsequent idea market conducted for GE's Energy division resulted in immediate funding for the top two ideas and plans to patent several others (Spears *et al.*, 2009).

KEY CHALLENGES

Over the past few years, there has been increasing interest in using market-based methods to gather information. Researchers have developed various types of markets to tap into the collective wisdom of a firm's employees, its potential customers, or the public at large. Whether prediction markets use real or play money, the general public or expert traders, a double-auction or market maker, the results are consistent. The resulting forecasts have a high level of absolute accuracy and are often clearly superior to the next best alternative method. More recently, pioneering efforts have shown the ability of a market mechanism to elicit and evaluate new-product ideas from employees or measure consumer preferences with respect to product concepts, attributes, or attribute levels.

Despite these advances, there are still challenges to be addressed for managers interested in deploying these tools within their organizations.

Long-range forecast accuracy of prediction markets. The forecasts arising from the prices in prediction markets tend to have a very short-term focus. Market predictions of political candidate vote shares are determined on the eve of election day. The accuracy of some HSX forecasts is based on how well the prices on Friday afternoon (the day a movie opens in theaters) predict the first weekend's box office receipts (Pennock *et al.*, 2000). In neither of these applications would these forecasts be actionable. More research is needed on the ability of prediction markets to make longer range forecasts such as those available from more conventional (statistical) methods.

Motivating traders. One of the prerequisites in obtaining an accurate forecast from a prediction market is a trader pool that includes a number

of motivated traders with expert-level insights into the outcome of interest. Internal prediction markets can use real money incentives to motivate potential traders to share their valuable information with the organization through their participation in the market. However, the use of real money incentives raises some organizational barriers. Top managers may question the need to pay their managers to participate in a prediction market. The participating managers should already be supplying the firm with the best possible information. On the other hand, without incentives, it may be difficult to motivate a manager with valuable information to spend time learning how to trade in the market. In general, monetary rewards are generally modest to avoid any potential conflict of interest between a manager's trades in the prediction market and his or her ability to influence the outcome being forecast.

Expanding the use of preference markets. The preference markets reported in the literature focus on different types of durable products (cellular phones, crossover vehicles, laptop bags, bicycle pumps, computer games). However, the consumer traders in all of these markets are very highly educated MBA students. The trading market software required training and knowledge of double-auction markets (e.g., limit orders vs. market orders). Learning to operate in such a trading environment should be easy for MBA students but may be considerably more difficult for the general public. Whether preference markets can be successfully applied in other product categories or with less analytically inclined consumer populations is an important area of future development.

SUMMARY

Leading companies including Google (Cowgill, Wolfers, and Zitzewitz, 2008), Best Buy, and GE are using various types of markets to access the collective "wisdom of the crowd" (Surowiecki, 2004). Whether the group is made up of employees or customers, there are new, market-based tools of discovery that leverage the reach and interactivity of the Internet to provide an engaging experience for participants and valuable information to organizations.

whole-product concept

Jeffrey B. Schmidt

LEVELS OF THE OFFERING

Product planners should see their organization's offerings in the market at three levels, as shown in the Figure 1, as customers do: core customer benefit, actual product, and augmented product (Kotler and Armstrong, 2010).

CORE CUSTOMER BENEFIT

At the most basic level, products and services are purchased to provide some perceived benefit(s) to the user. Marketers, designers, and product planners must determine "What is the customer *really* buying?" For example, a smart phone is more than a device that allows one to make phone calls, check email, access the Internet, and send text messages. Instead, it provides the freedom and the ability to connect to information and people from many locations. Similarly, a wristwatch might give the user the ability to be punctual for meetings and appointments, while certain watches might also communicate one's social

status (e.g., Rolex) or the activities that one is interested in or participates in (e.g., running, aviation).

ACTUAL PRODUCT

The actual product (or service) is how the core customer benefit is manifested or made available for consumption. Various features, design characteristics, and elements, the brand name, level of quality, and packaging, along with other attributes, comprise the actual product. In essence, the actual product is made from a collection of attributes (i.e., features, functions, and benefits) (Crawford and Anthony di Benedetto, 2008).

AUGMENTED PRODUCT

The outer level in Figure 1, the augmented product, consists of additional products, services, and benefits that enhance/facilitate buying (such as credit and delivery terms), using, and disposing of the product (e.g., after-sales service, warranties, and technical

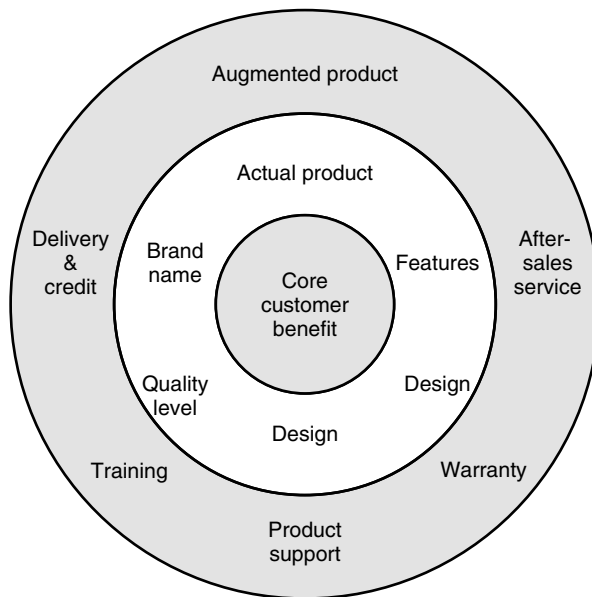

Figure 1 The whole-product concept. Source: Kotler and Armstrong, (2010).

2 whole-product concept

assistance). Components of the augmented product offer ways in which to differentiate offerings when customers perceive little variance in the actual product or service.

WHOLE-PRODUCT CONCEPT AND CUSTOMER VALUE PROPOSITION

VALUE PROPOSITION can be defined as what the customer gets, relative to competitors, compared to what he/she pays. Consequently, the whole-product concept and customer value proposition are related concepts. The

whole-product concept equates to what the customer gets; that is, it is the entire bundle of attributes and benefits.

Kano model of customer satisfaction¹

Barry L. Bayus

The Kano model of customer satisfaction is a widely cited approach for determining the types of customer needs (Kano *et al.*, 1984) (*see also* VOICE OF THE CUSTOMER; QUALITY FUNCTION DEPLOYMENT (QFD)). The Kano model adapts Fredrick Herzberg's ideas on the asymmetrical factors related to job satisfaction and dissatisfaction (i.e., job satisfaction is related to "motivators" like achievement, recognition, work itself, responsibility, whereas job dissatisfaction is related to "hygiene" factors like company policy, relationship with supervisor, work conditions, salary; Herzberg, Mausner, and Snyderman, 1959). Kano was working with the Konica camera company in the 1970s to develop some highly differentiated new products (Scholtes, 1997). Konica's sales and research groups discovered that customers only asked for minor improvements to the existing camera models. Kano, however, believed that really new innovations did not come from simply listening to what customers were verbally saying, but the development team had to develop a deep understanding of customer's real (latent) needs. Consequently, Konica staffers went to commercial photo processing labs to investigate the actual prints taken by customers. They found many mistakes and failures: blurry images, under and overexposure, and blank film rolls. Addressing these latent needs led to features such as auto focus, built-in-flash, and automatic film rewinding that are widely available in cameras today.

The key concepts in Kano's model are summarized in Figure 1. The horizontal axis indicates the degree to which a particular customer need is addressed in a (new or existing) product or service, ranging from completely absent to completely addressed. The vertical axis indicates how satisfied the customer is for a specific implementation of a customer need, ranging from delighted to disgusted. Within this two-dimensional space, three essential types of customer needs can be defined.²

The bottom curve, labeled *basic needs*, represents needs that are taken for granted and typically assumed by the customer to be met

(i.e., these are needs that "must be" satisfied). "The car is safe, it uses regular gasoline, it can be parked in a standard parking space" are examples of basic needs for an automobile. These needs are the "order qualifiers" and thus must be completely satisfied; these needs are needed to simply be in the game. Completely meeting basic needs cannot greatly increase customer satisfaction, but if they are absent or below par customers will not react favorably.

The middle curve, labeled *performance needs*, represent needs for which customer satisfaction is roughly proportional to the performance exhibited by the product or service (i.e., these needs are "linear" in that "more is better"). For example, greater gas mileage and longer lasting tires for an automobile are typically preferred. These needs are frequently requested by customers during the course of traditional market research studies, and are usually associated with predictable product improvements.

The upper curve, labeled *exciting needs*, represent needs that the customer does not expect to be satisfied. Thus, if this need is completely addressed the customer is delighted but if not, the customer does not really care. These needs are the "order winners" for customers. For example, side airbags, global positioning systems, airless tires that never get flat for automobiles might be exciting needs today.

The underlying message of the Kano model is simple, yet powerful. Customer needs are dynamic in that an exciting need today will eventually migrate to being a performance need and will become a basic need tomorrow (e.g., automobile air conditioning was a delighter in the 1950s, but is a basic need today; more recently antilock braking systems and cup holders that were once exciting needs have become standard equipment in most automobiles). Thus, customer expectations increase over time and, consequently, firms must continually strive to better understand evolving customer needs in order to stay competitive. A video tutorial of the Kano Model is at <http://www.kanomodel.com>.

ENDNOTES

¹ This article is adapted from material in Bayus (2008).

Figure 1 The Kano model.

²Other types of needs can also be defined based on the reverse of the curves in Figure 1, as well as needs for which the customer is indifferent (along the horizontal axis). See Center for Quality of Management (1993) and Matzler and Hinterhuber (1998) for a detailed discussion of methods to collect customer information that can be used to classify needs into these types.

value co-creation

Gaurav Bhalla

Value co-creation refers to innovation practices jointly undertaken by a company and its consumers, both current and potential (see OPEN INNOVATION). The primary purpose of value co-creation is to create *unique and specific value for individual consumers*. Contrast this with traditional marketing approaches, in which value is created for *average consumers*, either in the total market, or in particular market segments.

A simple case study will help illustrate the dynamics of co-creation.

Imagine it is the early 1990s. A lady, let us call her Bella, experiences an increase in acidity and stomach pain each time she eats a major meal. She visits a gastrointestinal specialist (GI), who diagnoses her condition as GERD (gastroesophageal reflux disease), and prescribes her Zantac. Bella accepts the specialist's diagnosis, does not contest his expertise, asks a few clarifying questions and leaves.

Now fast forward to 2010. There is another lady, let's call her Chuki, who also experiences an increase in acidity and stomach pain, following each major meal. She too visits a GI, who also diagnoses her condition as GERD, but prescribes a stronger medicine, an acid suppressant called *Prilosec*.

However, Chuki is not willing to merely be handed a diagnosis and a prescription. She has many questions, wants answers, and proactively engages the specialist in a conversation about her condition (see VOICE OF THE CUSTOMER).

- She informs the specialist of friends who have similar symptoms, but were diagnosed with IBS (irritable bowel syndrome).
- She refers to an article discussing common stomach ailments that she has printed from WebMD in preparation for her visit.
- She has read on the Internet that proper amounts of stomach acid help digestion. She wonders whether taking a drug that suppresses stomach acid is a smart idea.
- What about alternative remedies – like natural cures and home remedies, shouldn't she try them first?

The brief case study illustrates the DNA of value co-creation. Chuki is accepting of the specialist's expertise, but not to the total subordination of her own opinions and knowledge. For her, value does not merely lie in receiving a diagnosis and a prescription. Her concept of value is broader. It encompasses information, knowledge, and the assurance that the specialist is treating her as a unique patient. What is more, she is willing to work with the specialist to this end.

The rise of the internet-connected, well informed, globally aware consumer, has significantly altered the balance of power between manufacturers and consumers. Today's consumers are unwilling to be passive recipients of mass-merchandised value. Instead, through a blend of assertion, activism, and participation in web conversations, today's consumers are demanding that companies shape their offerings to uniquely meet their specific needs, in specific situations, at specific points in time.

This shift in power, with consumers no longer merely being a source of demand at the end of a value chain, has fundamentally altered the way in which marketing is practiced and value is created (Pralhad and Ramaswamy, 2004). In today's world, value is co-created by a company and its many customers/noncustomers. The consumer is a fundamental resource and input in the value identification, creation, and delivery process, and the co-creation experience is an integral part of the total value offering.

The key building blocks of co-creation of value are (Bhalla and Lawrence, 2010)

- *Listening*. learning about consumers' experiences; their angst, frustrations, desires, and aspirations (see OPPORTUNITY IDENTIFICATION);
- *Sustaining value co-creation conversations*. meaningful conversations that yield the raw material for co-creation;
- *Experimenting and rapid prototyping*. to manage risk, improvise, and enable speedy value co-creation (see PROTOTYPE);
- *Execution*. only when co-created value is delivered can the next round of value co-creation be initiated.

2 value co-creation

A few leading examples of co-creation of value follow. In the interest of space, web links are provided in lieu of detailed description.

- Nike + iPod allows gym fitness enthusiasts and runners to co-create their own fitness experiences and share it with similar others – www.nikeplus.com;
- You dream it, ASUS builds it, Intel inside – ASUS and Intel are combining forces to build the first community-designed laptop – <http://www.wepc.com>;
- Can innovation lead to evolution? Toyota believes it can. It is engaging millions of

people to co-create value in domains like water, air, and energy – <http://www.toyota-whynot.com>.

research & development

Jaideep C. Prabhu and Rajesh K. Chandy

WHAT IS R&D?

The Organisation for Economic Cooperation and Development (OECD, 2008) defines Research and Development (R&D) as “creative work undertaken on a systematic basis in order to increase the stock of knowledge, including knowledge of man, culture and society, and the use of this stock of knowledge to devise new applications.”

Research activities can be basic or applied. *Basic research* seeks to gain more comprehensive knowledge or understanding of a subject without specific applications in mind (National Science Board, 2010). Although basic research may not have specific applications as its goal, it can be directed in fields of present or potential interest. This is often the case with basic research performed by industry or mission-driven government agencies. *Applied research* seeks to gain knowledge or understanding to meet a specific, recognized need (*see* VOICE OF THE CUSTOMER). In business, applied research includes investigations to discover new scientific knowledge that has specific commercial objectives with respect to products, processes, or services (National Science Board, 2010). (*see also* SERVICE INNOVATION MANAGEMENT; PROCESS INNOVATION.)

Development is the systematic use of the knowledge or understanding gained from research or practical experience directed toward the production or significant improvement of useful products, services, processes, or methods (National Science Foundation, Division of Science Resources Statistics, 2006).

The main measure used to make comparisons of R&D activity across countries is gross domestic expenditure on R&D (GERD). This measure consists of the total expenditure on R&D by all companies, research institutes, and government and university laboratories within the country. (*see also* LOCALE OF INNOVATION.)

WHO DOES R&D?

Two main sources of funding drive R&D within countries: public and corporate. Public funding drives R&D activity in government labs and research institutes as well as in public universities. Corporate funding drives R&D within firms. The extent of public versus corporate funding that drives R&D differs across countries. In some countries, most R&D activity is funded by corporations and takes place within in-house labs. For example, in Japan and South Korea, 77% of R&D is funded by corporations (National Science Board, 2010). In other countries, the government is still the largest spender on R&D and most of this activity takes place within state-sponsored networks of institutes and labs. For example, in India, over 80% of R&D is funded by the state (Evalueserve, 2008). The overall spending on R&D also varies significantly across countries. While most developed economies (e.g., USA, Japan, and Sweden) spend more than the OECD average of 2.2% of gross domestic product (GDP) on R&D, most emerging markets (Turkey, Brazil, India, and Mexico) spend less than 1% of GDP on R&D (OECD, 2008).

WHERE IS R&D DONE?

Historically, most R&D has been done in the developed economies of North America, Western Europe, and Japan (the so-called triad nations). Governments in these countries have spent large amounts of money on R&D to ensure leadership in defence. Likewise, the largest firms in these countries, which also count among the largest firms worldwide, have spent significant amounts on in-house R&D as a way to achieve long-term advantages over their global competitors. Indeed, China, India, and Taiwan are all now in the top 10 highest spending countries worldwide in overall (purchasing power parity adjusted) R&D expenditures (Duga and Studt, 2008). Moreover, many firms from triad nations have, in recent years, increasingly conducted R&D activities offshore, in emerging markets like China, India, Taiwan, Brazil, and Russia. For instance, a recent study finds that China has the fifth and India the seventh largest number of R&D centers of the Fortune 500 list of largest

firms worldwide (Tellis *et al.*, 2009). This is particularly remarkable given that the trend toward offshoring R&D to emerging markets is barely two decades old.

R&D AS A CONCEPT AND A PRACTICE

R&D is a central concept in the vast academic literature on innovation (Thursby and Thursby, 2006). It is also a major instrument for policy makers striving to improve the competitiveness of their home economies and for managers seeking to improve the competitiveness of their firms worldwide (*see also* COMPETITIVE ADVANTAGE). While R&D is an important input into the innovation process, it does not guarantee that firms and nations that invest in it will naturally be more innovative. Indeed, a recent paper on innovation across nations finds that innovation and financial performance depend less on R&D spending per se, and more on firm-level cultural traits that enable firms to convert inputs into commercially valuable outputs (Tellis, Prabhu, and Chandy, 2009). Nevertheless, the tendency of firms, governments, and think tanks to monitor R&D spending is likely to continue in the future. The relative ease with which R&D spending can be measured (relative to innovation outputs) as well as its intuitive link with innovation outputs

will ensure it retains its appeal and power for some time yet.

value proposition

Shikhar Sarin

INTRODUCTION

Under increasing competitive pressure to keep costs down more and more, nowadays customers are focusing only on the price of the products they purchase. Without substantiation, a seller's claims of proposed benefits (i.e., value) are increasingly either ignored or dismissed outright as sales pitches and marketing charades (Anderson, Narus, and Rossum, 2006).

DEFINITION

A *value proposition* is the sum total of all the benefits a seller will deliver to the target customer in a purchase (Best, 2004; *see also* VALUE CO-CREATION). An ideal value proposition is built around the key benefits sought by the target customer; where the target customer could be either individual organizations in business markets or segments in consumer markets (Best, 2004). A well-delivered value proposition can contribute significantly to the business strategy and performance of both the seller and the customer (Anderson, Narus, and Rossum, 2006).

CONSTRUCTING A VALUE PROPOSITION

A compelling value proposition is distinctive, measurable, and sustainable. Properly constructed value propositions force sellers to meticulously focus on the worth of their offering to their customer.

Building blocks of a value proposition. The foremost step in constructing a value proposition is identifying key value drivers for the customer (Best, 2004) or the value elements of a seller's offering (Anderson, Narus, and Rossum, 2006). One can identify value drivers either by asking customers directly what they value or by using approaches like conjoint analysis (*see* PRODUCT DESIGN; PRODUCT SPECIFICATIONS) to examine how customers make choices involving tradeoffs between combinations of different product attributes (Best, 2004). Similarly, from a sales perspective,

sellers need to identify what they consider to be the key value drivers of their product offering (i.e., value elements). Once they have identified these value elements, the sellers need to ask themselves the following question: "From the customer's perspective, how do these value elements compare with those of the next best alternative?" Anderson, Narus, and Rossum (2006) suggest that on the basis of the answer to the above question, value elements of a seller's offering can be classified into three categories:

1. *Points of parity.* These are value elements that essentially offer the same performance or functionality as those of the next best alternative.
2. *Points of difference.* These are elements that make a seller's offering either superior or inferior to the next best alternative.
3. *Points of contention.* These are value elements about which the seller and the customer disagree regarding how their performance and functionality compares with those of the next best alternative (e.g., the seller considers a value element to be a point of difference, whereas the customer considers it to be a point of parity, or vice versa).

Types of value propositions. On the basis of these different value elements, sellers typically construct three kinds of value propositions (Anderson, Narus, and Rossum, 2006):

1. *All benefits.* These are value propositions in which the seller simply lists all the benefits they believe their offerings deliver to the target customer. This type of value proposition seeks to answer the customer's question, "Why should we purchase your offering?" An all-benefits value proposition requires the least amount of knowledge about the customer and the competitors, and the least amount of work in its construction. However, it often leads to benefit assertion by the sellers, where sellers create a laundry list of potential benefits. The problem arises from the fact that most of the benefits listed under this kind of a value proposition tend to be points of parity, which runs the risk of diluting the impact of genuine points

2 value proposition

of difference with the next best alternative. Moreover, in all-benefits value propositions, sellers tend to claim advantages for features that provide little or no actual benefits for the target customers.

2. *Favorable points of differentiation.* These value propositions seek to differentiate the seller's offerings from the next best alternative. A favorable point of differentiation value proposition attempts to answer the customer's question, "Why should we purchase your product instead of the next best alternative?" Constructing such a value proposition requires detailed knowledge of competitive offerings. However, without knowledge of the customer, favorable points of differentiation proposition can lead to value presumption on the part of the seller. In other words, there is an assumption by the seller that the favorable points of differentiation must be valuable to the customers.
3. *Resonating focus.* These value propositions make the seller's offerings superior on the few key elements that matter the most to the target customer. A resonating focus value proposition seeks to answer the customer's question, "What is most worthwhile for us to keep in mind about your offering?"

These propositions concentrate on one or two key points of difference that deliver the most value to the customer. Resonating focus value propositions are the hardest to construct, and require effort to gain insights into the value drivers of the customers.

To develop a compelling value proposition, the sellers needs to

- substantiate the value proposition (especially in financial terms);
- demonstrate customer value in advance; and
- document the value proposition in a manner that is consistent with the customer's priorities.

The reader is referred to Anderson, Narus, and Rossum (2006) and Best (2004) for further details on these aspects of a value proposition.

first-mover advantage

Shikhar Sarin

INTRODUCTION

The concept of first-mover advantage (FMA), or pioneering advantage, has attracted considerable interest for over three decades. Given its theoretical and managerial significance, the topic has drawn attention from researchers from a variety of disciplines including marketing (Kerin, Varadarajan, and Peterson, 1992), strategy (Lieberman and Montgomery, 1988), technology management (Tushman and Anderson, 1986), and economics (Glazer, 1985). The present discussion first defines FMA, and then explores its advantages and disadvantages from three distinct perspectives: economic, behavioral, and empirical. Finally, the directions of future evolution of this research stream are presented.

DEFINITION

Kerin, Varadarajan, and Peterson (1992) suggest that FMA generally refers to the widely held notion that being the first firm to pursue an opportunity is associated with long-term COMPETITIVE ADVANTAGE. A firm can achieve first-mover status in many ways, such as (i) being the first to produce a new product; (ii) being the first to use a new process; or (iii) being the first to enter a new market (Kerin, Varadarajan, and Peterson, 1992; *see also* OPPORTUNITY IDENTIFICATION). FMA is more complex than a simple order-of-entry effect; it incorporates a firm's ability to exploit and sustain any entry-related competitive advantage.

LITERATURE REVIEW

Academics and practitioners have long associated several advantages with being a first mover or a pioneer. Kerin, Varadarajan, and Peterson (1992, p. 42) note that pioneers preempt preferred "geographic space (locations), perceptual space (product characteristics space), distribution space (marketing intermediaries and shelf facings), and market segments (the largest and/or the most profitable)," which provide the first movers with superior resources

relative to followers in a market (*see* PRODUCT POSITIONING). FMAs have been explored from a theoretical-analytical perspective, as well as an empirical perspective; with the theoretical-analytical approach further being categorized into economic and behavioral perspectives (Kerin, Varadarajan, and Peterson, 1992). These perspectives are briefly discussed next.

Economic perspective. Several advantages accrue to first movers from an economic perspective, foremost of which is a high barrier to entry for the followers in the market. These barriers to entry are based on a variety of factors. First movers have a faster learning curve from production and sales, and achieve greater economics of scale relative to late entrants. Additionally, pioneers are able to preempt scarce resources, make critical initial investments (i.e., developing distribution channels), and lock up critical relationships (i.e., suppliers, distributors) in binding contracts before the late entrants. This creates supplier-specific learning and contractual switching costs that are hard for followers to overcome (Kerin, Varadarajan, and Peterson, 1992; Szymanski, Troy, and Bharadwaj, 1995).

First movers are able to better protect their brands, products, and organizational infrastructure owing to ownership of proprietary technology, patents, copyrights, trademarks, and trade secrets (Lieberman and Montgomery, 1988). Control of critical technologies allows pioneers to exercise technological leadership over late entrants (*see also* LATER MOVER (NONPIONEER) ADVANTAGE). First movers not only benefit from greater name recognition and reputational effects (Kerin, Varadarajan and Peterson, 1992) but they also enjoy a higher switching cost from their products. Because of asymmetric information about product quality, buyers perceive an inherent risk in adopting lesser-known follower brands, leading to a high switching cost for the buyers (Lieberman and Montgomery, 1988; Szymanski, Troy, and Bharadwaj, 1995).

The economic perspective suggests that by creating significant barriers for the late entrants, the first movers are able to extend the time during which they operate with little or no competition. They use this period to not only skim the market for profit, but also maneuver themselves into

2 first-mover advantage

a dominant position in preparation for competition from late entrants (Kerin, Varadarajan, and Peterson, 1992). While the economic arguments in support of pioneering are impressive, the advantages are not automatic. Any of the potential economic advantages accorded by the order of entry are dependent upon the firm's ability to exploit and sustain such advantages (Kerin, Varadarajan, and Peterson, 1992).

Counterarguments from the economic perspective. Pioneering is risky. First movers not only incur the high cost of research and development, but they also bear the high potential for failure (Golder and Tellis, 1993). Late entrants can free ride on the investments in technology and market development made by the pioneer (Lieberman and Montgomery, 1988). Moreover, followers can learn from the mistakes of pioneers, and enter the market with superior marketing strategies (Golder and Tellis, 1993; *see also* LAUNCH STRATEGIES; GROWTH STRATEGIES). Often, inertia from incumbency constrains a pioneer's ability to respond to market changes effectively, and in a timely manner (Lieberman and Montgomery, 1988).

The economic perspective largely overlooks the fact that product-market contingencies are likely to moderate any sources of FMA (Kerin, Varadarajan, and Peterson, 1992). For example, demand uncertainty is likely to influence whether the first mover, or the followers, enjoy sustained competitive advantage in the market. Similarly, market uncertainty and technological turbulence increase the risk that followers may leapfrog the pioneer during shifts in technology or customer preferences.

Behavioral perspective. Compared to late entrants, first movers encounter lesser resistance from the early adopters and innovators of a product (*see* PRODUCT LIFE CYCLE; BASS MODEL). In cases where customers are unfamiliar with a product category, first movers play a critical role in shaping the preference structures of the consumer (Carpenter and Nakamoto, 1989). First movers not only get to influence how attributes are valued but also the combination of attributes that are considered "optimal." Thus, pioneers get to define a product category and the prototype in that product category in their

favor; a standard against which all late entrants are measured (Carpenter and Nakamoto, 1989).

First movers enjoy a higher degree of consumer awareness than later entrants; they also find it easier to become a part of a customer's set of acceptable brands. This not only translates into higher product trials initially but also provides a basis for enduring sales advantage as the follower brands find it harder to penetrate the consideration sets of the customers (*see also* PRODUCT LIFE CYCLE; DIFFUSION OF INNOVATION; TAKEOFF; PRODUCT POSITIONING).

Counterarguments from the behavioral perspective. Kerin, Varadarajan, and Peterson (1992) note that there seems to be an inherent assumption in the behavioral perspective that the pioneer always offers a high-quality product, chooses the correct positioning, and pursues the right competitive strategy. This perspective further assumes that the late entrants are always reactive in their response and pursue a "me-too" strategy; since they lack the product offerings, business acumen, and organizational skills to attract the first mover's customers.

However, late entrants can learn from the pioneer's mistakes and develop superior marketing strategies (i.e., heavy advertising, more desirable positioning) that challenge the first mover's dominance (Golder and Tellis, 1993; *see also* LAUNCH STRATEGIES; GROWTH STRATEGIES; PRODUCT POSITIONING). Similarly, late entrants can choose to influence the consumer's preferences rather than simply reacting to them. Given that persuasive theoretical-analytical arguments can be found in support of, as well as against, FMA, many people look to the empirical evidence in this regard.

Empirical perspective. On the basis of a variety of data sources (i.e., PIMS database, sample surveys, and archival data), many empirical studies suggest a positive relationship between pioneering and market share, enduring sales advantage, firm survival, and profitability (*see* Kerin, Varadarajan, and Peterson (1992) for an excellent review; and Szymanski, Troy, and Bharadwaj (1995) for a meta-analysis), to the extent that the advantages of being "first to

market” have come to be regarded as conventional wisdom, or an empirical generalization.

However, other researchers have challenged this notion, reporting a negative relationship between order of entry and market share, long-term survival, and marketing and R&D expenses (Golder and Tellis, 1993; Kerin, Varadarajan, and Peterson, 1992).

This stream of research advocates firm growth and survival through following, rather than pioneering. A meta-analysis led Szymanski, Troy, and Bharadwaj (1995) to conclude that even though there is a positive association with market share, the overall empirical evidence in support of a direct effect of pioneering advantage is decidedly inconclusive.

Counterarguments from the empirical perspective. Several reasons have been suggested to help explain the mixed empirical support for pioneering advantage in the literature. Broadly, these inconsistencies can be attributed to the differences in the operationalization of pioneering, unit of analysis used (e.g., firm vs. strategic business unit (SBU) vs. brand/product level), sample heterogeneity and representativeness (e.g., survival bias; industry, business, or product type), and the measurement of performance (Lieberman and Montgomery, 1988; Kerin, Varadarajan, and Peterson, 1992; Szymanski, Troy, and Bharadwaj, 1995).

Past studies have operationalized pioneering in different ways. Some have operationalized it as being the first to develop a product or technology (not necessarily being the first to market), others have operationalized it as being the first to market (not necessarily being the first to develop), while still others have measured pioneering as being “one of the first” to develop a product or technology. This lack of consistency has led to contradictory findings because cases that might be considered as pioneering in one study would qualify as late entrants in a different study, and vice versa. In other studies, the distinction between first movers and followers may be confounded, leading to incoherent results.

Past studies have also been inconsistent about the level of analysis at which FMA has been examined. Some studies have examined the issue at the level of individual brand or

product-market; others have examined it at a SBU or firm level. While it is acceptable to use brand and product levels synonymously as long as the brand consists of a single product, however, in most cases, firms and SBUs are associated with multiple products (*see* ORGANIZING FOR INNOVATION). While firms and SBUs may be first movers in one product-market, it is unlikely to be the case across multiple products. Conversely, the effects of pioneering are likely to be strongest at the level of the single brand or product-market level; they are likely to get increasingly diluted and harder to isolate at higher levels of analysis.

Concerns have also been raised about sampling issues related to some of the past studies on FMA. Many empirical studies suffer from survivor bias, where the data do not account for firms, SBUs, and products that failed. This raises questions about the representativeness of the samples, and the validity of the findings related to pioneering-performance relationships (Kerin, Varadarajan, and Peterson, 1992).

Kerin, Varadarajan, and Peterson also note that many empirical studies pool data across diverse businesses and industries. This creates a heterogeneity bias, because diverse product-markets are likely to have different levels of concentration, entry and exit barriers, and other structural characteristics that could systematically affect the performance differences between first movers and late entrants. Finally, performance variables along which FMA is evaluated (i.e., market share vs. sales growth vs. profitability vs. survival), and their method of measurement (i.e., when these measurements are taken) can lead one to very different conclusions (Kerin, Varadarajan, and Peterson, 1992; Szymanski, Troy, and Bharadwaj, 1995). Once again, past studies show little consistency in this regard, leading to conflicting findings.

TOWARD CONTINGENCY MODELS OF FIRST-MOVER ADVANTAGE

The preceding discussion leads one to conclude that regardless of the perspective employed, the support for pioneering remains equivocal. This begs the question: Is there really an first-mover advantage? Emerging consensus suggests that

4 first-mover advantage

one of the leading causes for past inconsistencies may have been the simplistic main-effects approach employed by earlier studies. This approach focused on the direct link between order of entry and performance.

However, many omitted variables and contingent factors related to product, firm, and environmental characteristics can play an important moderating role in determining pioneering-performance relationship (Kerin, Varadarajan, and Peterson, 1992; Szymanski, Troy, and Bharadwaj, 1995). For example, it has been suggested that firm characteristics (e.g., size and incumbency), market strategy variables (e.g., breadth of the product line – see PRODUCT-LINE STRATEGIES; product quality, scale of market entry – see LAUNCH STRATEGIES; R&D reinvestment – see RESEARCH & DEVELOPMENT), and market environmental factors (e.g., market and technology growth rate – see GROWTH STRATEGIES; demand uncertainty) moderate the link between order of entry and performance.

Recent studies suggest that the pioneering-performance relationship may also be moderated by the characteristics of the innovation, such as radicalness of the innovation (i.e., continuous vs. discontinuous – see RADICAL INNOVATION), nature of the innovation (i.e., product vs. process innovation – see PROCESS INNOVATION), technological characteristics (i.e., network effects), and switching cost (Kerin, Varadarajan, and Peterson, 1992; Srinivasan, Lilien, and Rangaswamy, 2004; Varadarajan, Yadav, and Shankar, Forthcoming). Szymanski, Troy, and Bharadwaj (1995) find that a contingency approach to examining FMA has a significantly greater explanatory power, beyond the simplistic main-effects approach employed in the previous studies.

CONCLUSION

This discussion briefly explores FMA from economic, behavioral, and empirical perspectives. Each perspective offers persuasive

arguments in favor of, and counterarguments against, pioneering advantage. The evidence in support of a simple main effect of FMA remains ambiguous. A more nuanced contingency approach to examining FMA in the future might resolve some of the contradictory and inconclusive findings from the past. Recent trends are encouraging, and the area offers a fruitful opportunity for further research.

concept selection matrix

Jeffrey B. Schmidt

INTRODUCTION

Quality function development (QFD) is a technique that incorporates customers' needs and desires into various organizational processes such as engineering, design, marketing, and manufacturing (see QUALITY FUNCTION DEPLOYMENT (QFD)). The results of QFD are four matrices:

- Customer needs to performance measures (i.e., house of quality) (see Hauser and Clausing, 1988);
- Performance measures to features or solutions;
- Features or solutions to parts specifications;
- Parts specifications to manufacturing processes.

A variation on the second matrix, called the *Pugh concept selection*, was developed by Prof. Stewart Pugh of the United Kingdom. This variation attempts to evaluate different product concepts against the key performance measures of a "benchmark" or industry standard product with the goal of moving toward an "ideal" or near-perfect product concept. Pugh's concept selection matrix is a very effective for comparing concepts that are not refined enough for direct comparison using engineering requirements. This tool helps select the best design concept (or solution) from among alternatives, and, during the process, new concepts also may be generated.

CONCEPT SELECTION MATRIX

Concept selection entails both the processes of concept screening and concept scoring, each assisted by using a matrix (see Figure 1). For less complex solutions, only the concept screening matrix might be used, whereas more complex solutions might also require the use of the concept scoring matrix.

For both concept screening and scoring, the following six-step process is typically used by new-product design teams.

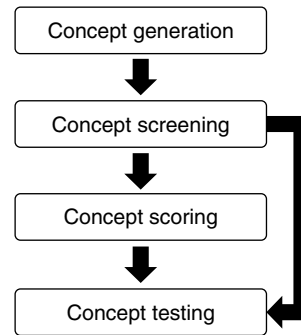

Figure 1 Concept selection.

- Prepare the selection matrix.
- Evaluate the concepts (design solutions).
- Rank the concepts.
- Combine and improve the concepts.
- Select the best concept.
- Reflect on the results and the process.

Each step of the concept screening is described briefly. Finally, concept scoring is discussed briefly, and a sample matrix is provided.

Step 1 Prepare the selection matrix: Using a matrix (on paper or in Excel, for example), the design team lists various possible concepts (or design solutions) on the horizontal axis and decision criteria on the vertical axis. These criteria are chosen on the basis of customer needs, and uncovered using VOICE OF THE CUSTOMER (Griffin and Hauser, 1993) and other marketing research techniques BRAINSTORMING. In addition, the needs of the organization (e.g., strategic importance, financial viability, fit with existing manufacturing techniques) should be considered.

Step 2 Evaluate the concepts (design solutions): The team chooses a benchmark (or reference) concept, which often is the industry standard or best-in-class product. The decision criteria for all concepts are rated against the benchmark concept.

Often a simple three-point scoring system is used (+, 0, and – for “better than”, “equal to,” and “worse than,” respectively) by the team to compare each selection criteria for each concept. When available, objective measures (cost, engineering specifications) may be used.

Table 1 Example of a concept scoring matrix.

| | Opportunity 1 | | Opportunity 2 | | Opportunity 3 | | Opportunity 4 | | |
|------------------------|---------------|----------------|----------------|----------------|----------------|----------------|---------------|----------------|----------------|
| | A | B ₁ | C ₁ | B ₂ | C ₂ | B ₃ | C | B ₄ | C ₄ |
| Decision criteria | Weight 1–5 | Rating | Score | Rating | Score | Rating | Score | Rating | Score |
| Strategically aligned | 4 | 9 | 36 | 5 | 20 | 7 | 28 | 1 | 4 |
| Acceptable market size | 3 | 6 | 18 | 8 | 24 | 2 | 6 | 10 | 30 |
| Financially attractive | 4 | 7 | 28 | 9 | 36 | 9 | 36 | 9 | 36 |
| Competitively viable | 5 | 8 | 40 | 6 | 30 | 9 | 45 | 9 | 45 |
| Understood needs | 3 | 8 | 24 | 5 | 15 | 3 | 9 | 9 | 27 |
| Technically achievable | 2 | 5 | 10 | 5 | 10 | 1 | 2 | 9 | 18 |
| Total score | | | 156 | | 135 | | 126 | | 160 |

Source: Haines (2009).

Teams may arrive at a consensus rating or may use an average.

Step 3 Rank the concepts: After rating the concepts, the number of “better than,” “equal to,” and “worse than” ratings are summed for each concept. An overall score for each concept is computed by subtracting the number of “worse than” ratings from the number of “better than” ratings. Then, each concept is ranked relative to competing or alternative concepts.

Step 4 Combine and improve the concepts: Next the team decides if the concepts make sense and whether there is a way to combine two or more concepts into an even stronger one.

Step 5 Select the best concept: For the fifth step, the team picks one or more concepts for further refinement and exploration. In some cases, it might be advisable to pursue multiple concepts at this point until such time when one emerges as clearly superior.

Step 6 Reflect on the results and the process: The results are discussed so that the team members are committed to moving forward with the chosen concept(s). At this point, the team should reflect on the process so that subsequent concept scoring exercises might be improved.

CONCEPT SCORING

The procedure for concept scoring is very similar to that for concept screening. The matrix in

Table 1 shows the main differences. Rather than rating a concept as better or worse than the benchmark, the team gives each decision criterion a weight from 1 to 5 (e.g., from not very important to very important). Then, each opportunity is rated from 1 to 10 as in this example (e.g., from unacceptable to outstanding). Each organization can use the scales and anchor points that fit best or are most useful.

In Table 1, opportunity 4 is optimum (total score = 160), followed closely by opportunity 1 (total score = 156). These two might be continued forward. On the contrary, opportunities 2 and 3 (total scores = 135 and 126, respectively) might be discarded or at least held until the two more highly ranked opportunities can be developed further.

society, culture, and global consumer culture

Eric J. Arnould

CONSUMER CULTURE

Consumer culture can be defined as a “social arrangement in which the relations between the [lived cultural experience of everyday life] and social resources, between meaningful [valued] ways of life and the symbolic and material resources on which they depend, is mediated through markets.” Consumer culture is a system in which consumption, a set of behaviors found in all times and places, is dominated by the consumption of commercial products. It is also a system in which the transmission of existing cultural values, norms, and customary ways of doing things from generation to generation “is largely understood to be carried out through the exercise of free personal choice in the private sphere of everyday life.” Furthermore, consumer culture is also bound up with the idea of modernity, that is, a world “no longer governed by tradition but rather by flux,” and in which “social actors who are deemed to be individually free and rational” hold sway (Slater, 1997, pp. 8-9). And finally, consumer culture derives from an economy in which value has been divorced from the material satisfaction of wants, and the symbolic value of goods takes precedence (*see* GLOBAL CONSUMERISM AND CONSUMPTION).

In consumer culture, predispositions toward social emulation, matching, and imitation expressed through marketplace choices are accompanied by a penchant for differentiation, individuality, and distinction also expressed through marketplace choices. Together, these motives drive a rapid turnover in goods and services. These dynamics are often thought to have been triggered by the purposeful social engineering of twentieth-century marketers, advertisers, and retailers and to have spread from roots in the fashion industry into all parts of social life (Featherstone, 1991, p. 115).

Four crucial aspects of consumer culture include

1. the pervasive and rapid circulation of commercial products, that is, things

- produced for exchange within a capitalist market, take priority over and above things redistributed by governments through the welfare state or exchanged among social groups through gift giving;
2. the relative independence of consumption activities from those related to production, and the growing power and authority this gives to some consumers over market dynamics;
3. changes in the relationships between different systems of production and valuation in society such that these are all increasingly interlinked and mediated by market values; that is, answers are sought to questions like “How much does it cost?”, “How much will someone pay?”, and “How much am I worth?”
4. the special importance given to the use of consumer goods in the allocation of individual status, prestige, perceived well-being, and quality of life (Lury, 1996, p. 4).

Consumer culture is influenced by agents who work directly in the market economy as managers, marketers, and advertising “creatives”; by independent “brokers” who analyze and criticize consumer products; by cultural intermediaries such as media figures (e.g., movie and television stars, celebrity chefs, religious broadcasters, public intellectuals, politicians, etc.) who sculpt and disseminate attractive models for consumption behavior; and by dissidents who initiate alternative responses to the mass-consumption system, responses that are typically reappropriated into the global market as differentiated, niche products.

GLOBAL CONSUMERS

The consolidation of scientific economics and modern market institutions took place in the eighteenth century, which was also when the social role of the consumer, combining traits of hedonism and rationality, was distinguished from the putatively wasteful and irrational elite of the ancien regime. The early twentieth century consumer was a mass-market consumer, whereas today’s consumer is characterized by a general emphasis on individual style, paralleling the customization and niche marketing that has

2 society, culture, and global consumer culture

overtaken the economy. The tendency within consumer culture today is that consumers' lifestyles no longer require coherence; marketers and cultural intermediaries (fashion, entertainment) cater to and expand the range of styles and lifestyles available to global audiences with little emphasis on cultural authenticity or prior tradition (Featherstone, 1991, p. 26; *see* GLOBAL CONSUMERISM AND CONSUMPTION).

And just as the consumer was theorized into existence by the economic philosophers of the eighteenth century, and turned into the linchpin of twentieth-century economies by economic policy makers and Madison Avenue advertisers, so the consumer continues to be recreated on the global stage. For example, Dávila (2001) carefully traces the evolution of Spanish language media in the United States, as well as advertising specifically designed for Latinos. The dynamics of these initiatives prior to the 1980s often involved promotions aimed at Latin American countries that were then adapted and transplanted to the United States. Cuban advertising entrepreneurs and cultural capital and networking links generated by the Cuban-American ethnic economy proved central to the development of Latino media. She demonstrates that an emphasis on stereotypical "traditional" family values is at the crux of Hispanic marketing strategies, and the constitution of the Hispanic consumer, by these media. She notes how important uniting Latinos across difference of nationality, class, color, and political ideology has been in building an image of the Latino market for corporate clients (*see* PRODUCT ETHNICITY; GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES).

Further, Cayla and Eckhardt (2008) investigate how Asian brand managers forge new webs of interconnectedness through the construction of a transnational, imagined Asian world. Some brand managers are creating regional brands that emphasize a putatively common experience of globalization, evoke a generic, hyperurban, and multicultural Asian experience, and contribute to the creation of an imagined Asian as urban, modern, and multicultural (*see* GLOBAL BRANDING: THREE KEYS FOR

GLOBAL BRAND SUCCESS; GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES).

Finally, Mazzarella (2003) has documented in greater detail how Indian marketing professionals marshaled ideas about Indian cultural distinctiveness along with stereotypical local notions of tradition and modernity to create a differentiated image of the Indian consumer to market to multinational corporations (*see* BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS; RESEARCH & DEVELOPMENT).

GLOBAL CONSUMER CULTURE

Global consumer culture is driven by the extension of market principles into every corner of the planet. Global consumer culture is a desired ideal for many new consumers, and at the same time, a contested foreign ideology for some political and religious groups, and a social process that is continuously evolving through shifting business relationships, competition, technological flows, and media expressions.

More specifically, the spread of consumer culture globally is conditioned by the global flow of distinctive cultural resources including what Appadurai (1990) refers to as *financescapes*, *technoscapes*, *ideoscapes*, and *mediascapes*. *Financescapes* refers to global flows not only of capital and currency but of various financial instruments that facilitate markets (*see* INTERNATIONAL PRICING OBJECTIVES AND STRATEGIES). The derivatives market, the remittances business, and the microfinance revolution are all examples. Remittance businesses have facilitated both the global movement of workers and also the transfer of consumption resources to the global south. The microfinance revolution has also driven market models of finance and consumption into the hands of the global poor.

Technoscapes refers to global flows of informational and mechanical technologies of both simple and complex varieties across borders. Integrated global supply-chain management at one scale of complexity (*see* DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES), and the global cell-phone revolution at another are cases in point. Global

consumer culture also depends upon global media to create a sense of global identification and memory without which any cultural identity is incomplete. Thus, televised global consumption spectacles such as the millennial celebrations, and the quadrennial World Cup and Olympic festivals are implicated in the spread of consumer culture (see DIGITAL MEDIUM AND GLOBAL MARKETING).

In the global mediascape, privatized commercial media empires (e.g., NewsCorp) now coexist with decentralized and fragmented small media, diverse in economic and social organization such as the cassette music and video cultures that have become ubiquitous in the global south. Media of many forms play crucial roles both in shaping national imaginaries including national consumer prototypes such as the prototypical Indian, "Asian," or Chinese consumer (Dávila, 2001; Cayla and Eckhart, 2008; Mazzarella, 2003) mentioned above (see INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?).

Ideoscapes refer to the ideologies of states and other movements that contend for popular legitimacy and authority. Globalization and standardization of modern consumer culture around the world have, in turn, stimulated localization and heterogeneity of demand as well as contestation and resistance to global companies and brands (Featherstone, 1991). Ideoscapes then include such things as models of consumer culture carried by global media; various reactions such as the anticonsumer No Logo movement, the rejectionist stream of Islamic fundamentalism that views film, music, fashion, and other trappings of consumer culture as anathema; and, more reformist movements like the local food and Slow Food movements (see FORCES AFFECTING GLOBAL INTEGRATION AND GLOBAL MARKETING).

Globalization also means that cultural encounters proliferate through these earthscaping processes, which has led to an increasing interest in identity-constructive processes through consumption. Thus, global consumer culture involves the globalization of desires; of the responsibility to seek an individual sense of self through material symbols; the need to emulate; the attraction of a market-mediated material

world; of homogenized images of the good life (Clammer, 1997, p. 14); and an experience of fragmentation of social life on the receiving end of globalization that fuels idealist and rejectionist reactions (see GLOBAL CONSUMERISM AND CONSUMPTION).

Structures of common difference. Globalization is accompanied by a heightened sense of disjuncture and disorder, as rapid earthscaping has upset and displaced relationships between the economic center and periphery of the global economy, and between local cultural forms and cultural contents. These earthscaping processes and the novel technologies, media, ideologies, goods, and relations they carry "nevertheless often remain closely tied to professional, political, and economic interests that have important stakes in mobilizing and regulating global markets." These interests, "even as they capitalize on the proliferation of 'cultural difference,' also demand that such cultural difference be rendered manageable as content within globally reproducible (and thus marketable) forms and genres" (Mazzarella, 2004, p. 351; see FORCES AFFECTING GLOBAL INTEGRATION AND GLOBAL MARKETING; MARKET ENTRY AND EXPANSION). This has led to the identification of what have been called *global structures of common difference* in global consumer culture.

The creolization of consumption patterns that combine elements of local and foreign consumption traditions through globalized institutional forms is ubiquitous within global consumer culture. This is the diffusion of "structures of common difference" (Wilk, 1995). Thus, global fast-food chains reproduce an institutional formula across many cultural locations. McDonald's is present in most local markets, but often undergoes significant alteration in what is offered and how. Thanks to local modifications of the McDonald's formula, the Jolibee fast-food chain at one time enjoyed a 59% market share in the Philippine fast-food market. Similarly, traditional Turkish fast food called *kebab*, has experienced a revival as Western-style fast-food outlets have penetrated the Turkish market. And Turkish entrepreneurs in Germany offer Turkish *shish kebab* in McDonald's-like settings.

4 society, culture, and global consumer culture

These choices allow Philippine, Turkish, and Turko-German consumers to express varying degrees of cultural conformity and cultural difference through their fast-food choices (*see* INTERNATIONAL FRANCHISING).

Similarly, the beauty pageant has become a popular consumer global celebration. In Belize in Central America, some pageants judge contestants according to Euro-American ideals of beauty; others celebrate Caribbean values of respectability and reputation and express tensions between different ethnic groups that hold different value orientations (Wilk, 1995). Soap operas, comic books, and musical forms provide other examples of global structures of common difference. The Hong Kong, Hollywood, and Bollywood industries provide three intertwined global institutionalized forms (Stearns, 2006, p. 150). And scholars have pointed out that Christmas has become the first global consumer holiday, a structure of common difference that accommodates dramatic differences in cultural content within a shared seasonal and aestheticized institutional format.

Brands. Brands have become a ubiquitous structure of common difference in global consumer culture: the Coca Cola logo and Nike Swoosh are brand symbols that trigger myriad responses; their cognitive salience and ability to arouse passion are undeniable (*see* GLOBAL BRANDING: THREE KEYS FOR GLOBAL BRAND SUCCESS). When people demonstrate against the inequities of globalization, they use brands such as Coke or McDonald's as symbols of corporate power. Brands have become cultural forms; they encapsulate ideas about the way people should live, look, and think. Branding is a specific form of communication that tells stories in the context of products and services, addresses people as consumers, and promises to fulfill unmet desires and needs. In other words, branding is a specific symbolic form, a particular way of talking about and seeing the world.

"The rise of a global culture does not mean that consumers share the same tastes or values. Rather, people in different nations, often with conflicting viewpoints, participate in a shared conversation, drawing upon shared symbols. One of the key symbols in that conversation

is the global brand" (Holt, Quelch, and Taylor, 2004, p. 70). Global brands are most often associated with a quality signal that is important worldwide; global brands set a standard. Hence, global companies are advised to compete aggressively on quality signals while addressing consumers' skepticism about them. But global brands simultaneously create openings for local brands that convey enduring local meanings. Global brands also convey a myth of global cosmopolitanism to which many consumers worldwide aspire. Therefore, global companies are advised to associate global myths of individual independence, modernity, and self-actualization with their brands. Finally, global brands and global companies "wield extraordinary influence, both positive and negative, on society's well-being. Many consumers expect firms to address social problems linked to what they sell and how they produce and distribute their products and services" (Holt, Quelch, and Taylor, 2004, pp. 71–72). Thus, to improve their global image, firms are advised to undertake initiatives that benefit stakeholder communities (*see* MARKETING'S CORPORATE RESPONSIBILITY).

REGIONAL MANIFESTATIONS OF GLOBAL CONSUMER CULTURE

OECD countries. The Organisation for Economic Cooperation and Development (OECD)-countries represent the most-developed market economies in the world, primarily, the Euro-American nations. In these countries, there is a steady multiplication of purchase opportunities and the extension of consumer orientations into areas of activity that used to lie outside the consumer domain, such as politics, higher education, art, place, and even interpersonal relationships. The center of the culture of consumption is marked by an oversupply of goods of all sorts including symbolic goods leading to a tendency toward cultural disorder and destructuring (Featherstone, 1991, p. 13). Individuals are encouraged to adopt a nonutilitarian attitude toward commercial goods and services and to carefully choose, arrange, adapt, and display goods to make stylistic statements that express the individual, presumably, authentic identity of the owner (Featherstone,

1991, p. 114), leading also to new consumer engagements in value-creation processes.

Four other trends can be noted. First, OECD countries are moving toward a dematerialized service economy (see SERVICES GLOBALIZATION). Second, trends toward recreational and luxury shopping have grown. Third, while elite consumers in other cultures have swelled the ranks of world tourism in recent years, North America and Europe have traditionally constituted large tourist markets. The motives that inspire tourist consumption are diverse, ranging from nostalgic visits to historic towns and villages, to escapist entertainment at Mardi Gras, to romance at a Club Med or on a cruise, to extraordinary adventures through African safaris, Himalayan trekking, or Outward Bound trips.

Fourth, is the advent of sustainability in consumer behavior that takes into account environmental concerns, that is, waste and resource depletion; social concerns, that is, “ethical” consumption, boycotts and boycotts, progressive human resources policies; and the efficiency and efficacy of firm operations themselves (see GLOBAL MARKETING ETHICS; EMBARGOES AND SANCTIONS). Negative (resistance) and positive (ethical buying) forms of political consumerism now seem to concern a wide sector of the population. Recent survey data on Europe, for example, show that over 30% of the population of Denmark, Great Britain, Germany, Italy, Norway, and Portugal are boycotting products for political reasons, choosing specific items because of their ethical or environmental qualities, or participating in the activities of consumer-oriented associations (Sassatelli, 2006, p. 221). Ethical consumerism is being reframed as consumer freedom and as a duty.

Consumer culture in Japan, the BRIC (Brazil, Russia, India, and China) countries, in the countries that were formerly part of the Soviet bloc, and in Africa (see below) has been “heavily foreign, a clear import, even as it appealed to both new and traditional interests. Foreignness, in turn generates three reactions. The first involves the appeal of the strange and . . . the modern . . . second, foreignness prompts resistance, in the name of customary but also newer national

identities . . . Third . . . consumerism is appropriated, becoming as ‘natural’ as it was in the West” (Stearns, 2006, p. 81).

Japan and the Asian “Tigers”. As one of the wealthiest nations in the world, Japan, representing a huge market, quickly adopted a culture of consumption after World War II. The direction of Japan’s economic progress since World War II foreshadowed similar changes in other countries of the Pacific Rim, the so-called “tigers.” While, Japan shares many historical values with other East Asian countries, export of finance-, media-, techno-, and ideoscapes originating in Japan have been instrumental in fueling the expansion of consumer culture in this region (see STRATEGIC EXPORT MARKETING—ACHIEVING SUCCESS IN A HARSH ENVIRONMENT).

A characteristic of Japanese consumers is that they are highly informed and aesthetically sophisticated. They are actively engaged in creating their sense of identity in terms of gender, age, and lifestyle (Clammer, 1997, p. 12). Further, there is less Puritanism (i.e., Protestant asceticism) and no moral condemnation attached to acquiring material goods in Japanese culture (Clammer, 1997, p. 14). Two interesting features of consumer culture in Japan are first, the association of high quality and price, hence a desire for brand-name goods, and the following of expensive fads; and second, the very high rate of discard and replacement. This reflects the fact that variety or originality are devalued in Japanese consumer culture relative to newness or up-to-dateness (Clammer, 1997, p. 24).

Japanese household budgets show interesting characteristics. Budget proportions spent on necessities, furniture, and household goods have declined, while amounts spent on leisure and luxuries have increased although there is still a high level of savings reflecting Japan’s particular adoption of consumer culture historically, and such things as the high costs of housing and education. Gender differences are also significant, with rapid increases in women’s discretionary expenditures. *Depāto* – department stores – which have gone a long way in commercializing Japanese cultural values and domesticating foreign consumer tastes, are also among the biggest promoters of “traditional”

Japanese gift giving – a large, distinctive, and socially important category of consumer expenditure in Japan (Clammer, 1997, p. 18). Japanese gift giving is a commercialized form of modern intimacy, a form that creates bonds without much moral substance, by contrast with China where commensalism is an important basis of social bonding (Clammer, 1997, p. 19).

BRIC countries. BRIC literally refers to Brazil, Russia, India, and China, but may include a number of countries with rapid economic development and growth in consumer culture, thus including countries like Turkey (see EMERGING MARKETS). In all these countries, the emergence of powerful local brands such as the Murat, Mahindra, and Tata automobile brands in Turkey and India, respectively, and large local consumer markets is a big part of the story of global consumer culture in the twenty-first century. Another part of the story is the persistence of large numbers of subsistence consumers at the base of the economic pyramid, who live on at best a few dollars a day and whose needs and aspirations have only recently begun to register on global marketers.

In China, the spread of consumer culture has been fostered by the existence of strong consumer interest before the nineteenth century as part of an urbane, secular worldview. The appeal of “an almost fantasy-like modernity” that promises some release from “customary hierarchies and constraints” (Stearns, 2006, p. 109) has also fostered the recent expansion of consumer culture. Finally, economic reforms post-1979 have diminished state power dramatically and freed many consumers from political strictures on consumption.

The World Bank estimates that 250 million to 300 million people have climbed out of poverty since China adopted economic reforms. One big story is the growth of a consumer middle class in China. In 2005, at least 4.5 million had a disposable income in excess of US\$30 000 (Latham, 2006, p. 9). Characteristic of the effects of consumer culture everywhere, consumer culture is fueling the emergence of new “disjunctures and differences” in Chinese consumption practices (Latham, 2006, p. 3), new scope for Chinese citizens, especially women, to

express their personal taste, ideals, and values as against older collective forms.

As in other places, distinctive characteristics of consumer culture are emergent in China. Among these are the idea of consumption as a palliative to continued tight state control of political freedom and the media; the articulation of various local understandings of Chinese history and character in its branding practices, and the role of consumer goods in vitalizing China’s gift economy and, in particular, the web of interpersonal relationships often referred to as *guanxi* (Latham, 2006; see INTERNATIONAL RELATIONSHIP MARKETING). Others have commented on China’s one-child policy in creating the more hedonically oriented Chinese consumer of today. The speed of economic development and the success of the one-child family policy has fomented a consumer revolution across all social strata. The claims of Chinese children on their family’s financial resources are larger and more uniform across economic strata than for children elsewhere.

Much continuity persists in Chinese consumer culture as well; one example has to do with the place of food in society. As Mintz (2007) evocatively writes,

It is at table that children learn to become adults; at table that babies meet their grandparents; at table that people display their civilization and communicate it. To watch the giver of a restaurant banquet—some paterfamilias welcoming the family of a son’s fiancée, celebrating a grandchild’s birth, or just treating friends—is to get a sober lesson in etiquette, self discipline, and joy.

In India, the growth of a middle class representing 30% of the population, or 250 million people is the big story of the early twenty-first century. Still, it is likely that no more than 100 million or so of this middle class represents a truly consumerist segment. As in China, participation in consumer culture is associated with cosmopolitan values like modernity, democracy, and even liberation. Nonetheless, the majority of the larger group remains committed to a savings orientation; Indians tend to save 25% of their incomes and place their savings in cash accounts rather than in financial instruments.

Across the population, about half of all discretionary expenditures are for important family ceremonial activities (Srinivas, 2008) rather than for the satisfaction of individual desires, indicative of the enduring role of family in structuring consumption practices. On the other hand, there is a huge aspiring class, perhaps as many as 260 million, striving to attain middle-class status, with maybe 15 million joining the middle classes each year (Srinivas, 2008, p. 11) who may engage in bouts of conspicuous spending. The Indian middle class is also divided along the fault lines of geography, especially the north-south divide, education, profession, especially differences between the private and public sector, class, and caste.

Researchers have found that the vast masses at the base of the Indian economic pyramid are also affected by the spread of consumer culture. "Increasing desires to consume branded goods that are advertised through television is ... a consistent and recurring theme." Moreover, "intertwined cultural processes of conspicuous consumption, normative change [imposing a link between consumer goods and morality], and [interpersonal] competition" mark narratives of low-caste Indian consumers. They reflect an increasingly consumerist content of Indian media that depicts the mythic lifestyles of the rich and famous (Varman and Belk, 2008, p. 236, 237).

Russia and the former Soviet bloc. In Russia and other former Soviet bloc countries, the introduction of consumer culture has been inflected by the "debate about whether West should be model or pariah" (Stearns, 2006, p. 86). "Hesitations" rooted in the Soviet experience and Eastern Orthodox religious traditions persist (Stearns, 2006, p. 91). In all these states, there is a legacy of an effort to build an alternative to Western consumerism that emphasized workers' vacations, and workers' rights rather than consumer service. Further, there was a tradition of elite consumption that was both unacknowledged and secretive, a tradition that has reemerged in the spectacular nouveaux riche consumption behavior of the "new Russians," who profited from the Soviet Union's transition to market capitalism.

Latin America. In Latin America, a widespread class of wealthy landowners and a few merchants and mine owners provided a spur to consumerism in the nineteenth century and a model of European, and secondarily North American imitation that continues to color consumption, particularly, in countries like Argentina. Another characteristic of Latin America is the influence of American chain stores, first Sears Roebuck in the 1920s and later Wal-mart and some European chains in the 1980s and 1990s that began to extend Euro-American models of consumption to middle-class buyers. The middle classes that have aspired to Euro-American consumption standards have grown dramatically, though erratically, in Brazil and other Latin American countries since the Second World War. Of course, Latin America also encompasses dramatic cultural diversity that colors consumer preferences; in indigenous communities, sometimes, new consumer opportunities fuel cultural ideals that are a legacy of reciprocal social relations and new status hierarchies simultaneously. Latin America's centuries-long legacy of economic reliance on raw materials exports has produced a huge underclass of subsistence consumers, many of indigenous backgrounds, who struggle to enjoy basic consumer goods. These consumers are increasingly targeted by multinationals with custom-tailored products, creating new sustainability challenges (see EMERGING MARKETS). Finally, Latin America has also become an important source of exported consumer culture through such things as food (especially Mexican and, more recently, Argentinean culinary styles), music, and dance styles (Mambo, Tango, Meringue, Samba, etc.), and traditions of sumptuary seasonal consumption associated with Carnival and other traditions (Stearns, 2006, pp. 112–114).

Africa. Four intertwined themes concern Africa's engagement with consumer culture. First, in the nineteenth and twentieth centuries, as Africa was incorporated into the global economy through the sales of raw materials or labor to western interests, consumption became a practice allowing some to emphasize individual identity at the expense of forms of identity based on kin groups such as lineages and clans.

Imported consumer goods from Europe and, more recently, from Asia provide vehicles for constructing “modern” cosmopolitan consumer lifestyles. Today, exotic consumer goods from the metropolitan countries are used more widely to convey status and prestige. Cars (see the “mama Benz” of Togo or the wa-Benzi of East Africa), clothing, and buildings, both private homes and public buildings such as mosques, have become important indicators of status (*see* CONSUMER WORLD-MINDEDNESS).

Second, longstanding precolonial consumption practices typically remain strongly rooted, even as contemporary practices associated with the colonial and postcolonial experiences are layered over them. Thus, the share of household expenditures on food remains relatively high even at higher levels of income. The likely explanations for this pattern are relative poverty, the weakness of formal financial investment opportunities, and the normative importance of social investments in networks of kin, credit, and cult. Consumption of traditional products has, in many cases, persisted and, indeed, thrived. Fish from the inner delta of the Niger and the east African lakes, livestock and hides produced in semiarid regions, salt and dates produced in desert oases; kola nuts from the Guinea coast, and khat in the Horn region are some examples. Kola nuts, widely traded in West Africa, continue to play an important role in symbolizing hospitality, marital alliance, political affiliation, and ritual obeisance. Among the poorer consumer segments, motivations driving consumption choices are achieving increased family solidarity or social standing within local prestige networks, not individual consumer utopia.

Third, creolized consumption is ubiquitous. For example, there has been an explosion of fast food in African countries. Traditional fast food is mainly prepared with indigenous ingredients and to conform to local taste. “Foreign” models are more diversified, as urban populations embrace consumption patterns broadly similar to cosmopolitan ones under the impetus of resource availability and following “modern” trends. Proliferating fast food can be found in most of the larger African urban centers. Creolized clothing consumption may reach its apogee in the behavior of Congolese *sapeurs* who

participate in elaborate rituals of conspicuous consumption of French fashions that incorporate traditional ideas about the accumulation of life force. Africans also have become avid producers and consumers of creolized music and video products, incorporating local, South Asian, and New World sources.

A fourth trend is the African consumers’ imaginative engagement with alternative modern worlds that are different from their own but also without the ideological and political baggage associated with the west and the former colonial powers. The Islamic Middle East and Hindu South Asia offer alternative models of consumption.

The Islamic Middle East. The interaction between Islam and consumer culture represents interplay between ongoing spiritual and nationalist values and the new lures of displays of materialism. This occurs against a backdrop of public debate over secularism represented by countries like Turkey, Lebanon, Morocco, and Egypt, and Islamic religious nationalism represented by countries like Saudi Arabia, Iran, and the Sudan. A strong rural–urban, rich–poor divide, and between those who have benefited from oil revenues and those who have not, colors attitudes toward consumption (Stearns, 2006).

Huge numbers of internal migrants from rural villages to urban slums also find their consumption choices suspended between the expression of secular and religious values. Thus, poor consumers illustrate three modes of acculturation: in some cases, migrants reconstitute their village culture in the city, shutting out the consumerist ideoscape; or they collectively pursue the consumerist ideoscape as a myth through ritualized consumption; or they give up on both pursuits, resulting in anomic results for identity. Meanwhile, elite consumers in the Islamic Middle East are avid consumers of Western luxuries and middle-class consumers are often avid consumers of Western fashion and media. Among middle-class Islamists, Islamic fashions in dress, and gender-segregated options in shopping and luxury vacations have grown dramatically in the past 20 years (Üstüner and Holt, 2007; *see* PRODUCT ETHNICITY).

RESISTANCE

Critique of and resistance to the spread of consumer culture is as old as the emergence of consumer culture in the eighteenth century. Systematic critique of the institutional bases of consumer culture has been offered by social theorists that highlights the alienating, dehumanizing effects of materialism; others have commented on the envy, possessiveness, and nongenerosity that commitment to consumer culture sometimes entails (*see* GLOBAL MARKETING ETHICS). Some classic expressions of resistance to consumerism have declined in recent years in the OECD countries although the critique of “irrational” lower class consumption or women’s alleged frivolity persists in newer consumer cultures. Global consumer culture has, nonetheless, fostered a virulent backlash. Religious, environmentalist, nationalist, and anticorporate critiques have emerged with considerable vigor. Many of these forms of resistance appear to be motivated by a global sense of anxiety about the risk to life and happiness provoked by the globalization of consumer culture itself. In one study of global brands, the authors found “thirteen percent of consumers are skeptical that transnational companies deliver higher quality goods.” They dislike brands that preach American values and don’t trust global companies to behave responsibly. Their brand preferences indicate that they try to avoid doing business with transnational firms (Holt, Qulech, and Taylor, 2004, p. 74).

Antiglobalization activism is a diverse movement with some groups promoting various anti-corporate or anticonsumption positions. Some call for deconsumption; others dispute specific elements of global value chains such as the use of GMOs (genetically modified organisms) and sweatshop labor; still others promote alternative fair-trade brands; and still others promote local or regional brands such as Mecca Cola (Egypt) or Qibla Cola (Peru), ideologically positioned as explicit competitors to their multinational counterparts (note the influence of global structures of common difference here). Antiglobalization takes many forms, not all of which are truly resistant to consumer culture.

One difficulty of antiglobalization activism lies in the tendency for oppositional forces whether political or cultural to be co-opted by the global mediascape, which increasingly mediates between grass-roots popular cultural manifestations and mainstream corporate consumer culture. For example, Starbucks, the nation of Ethiopia, and the NGO OXFAM waged a recent battle over the right to trademark regional Ethiopian coffee varietal names such as Yirgacheffe, Harrar, and Sidamo. The struggle concerned the right to extract a greater share of the retail value of these regionally branded coffees either for Ethiopian producers or for Starbucks. A vicious court and public-relations battle eventuated in a victory for OXFAM activists and the Ethiopian coffee industry, which may now retain the branding rights (*see* GLOBAL BRANDING: THREE KEYS FOR GLOBAL BRAND SUCCESS). Similarly, in the United States, local coffee houses and regional chains are able to position their brands as anti-Starbucks brands, and incorporate various local, fair-trade, organic, bohemian, and other associations into their brand images that Starbucks cannot claim. But these “doppelganger” brands (Thompson, Rindfleisch, and Arsel, 2006) are as much a part of global consumer culture as the global brands they critique.

global consumerism and consumption

Russell Belk

A STORY OF GLOBALISM

In a 1954 *Uncle Scrooge* comic book story by Carl Barks, the rich but penurious Scrooge McDuck is besieged by people wanting favors. A Middle East oil sheik threatens to nationalize his oil wells if Scrooge does not give him a limousine. Others just want money. The pressures of dealing with all this cause Scrooge to have a nervous breakdown. His doctor recommends that he go to a place where there is no money: the land of Tralla La. So Scrooge has one of his pilots fly him, Donald Duck, and the nephews to this mysterious land in the Himalayas. They must parachute into the fog-enshrouded valley, but before they jump Scrooge opens and downs a bottle of the nerve tonic medicine that his doctor has sent with them. The bottle cap falls innocently into the valley and the ducks follow. When they land they find that the natives are blissfully happy and give the ducks meaningful work in their peaceful community. Uncle Scrooge becomes a brick mason and soon finds that his cares and stresses have melted away. Since he no longer has a need for the nerve tonic, he heads to the lake to pour out his remaining six bottles. In the meantime, one of the villagers found the bottle cap that fell from the plane and shows it to his friends. They have never seen anything like it and start a bidding war that quickly escalates into offers of all they have in exchange for the cap. Back at the lake, as Scrooge starts to dispose of his medicine, one of the villagers sees his six shiny bottle caps and excitedly observes that he is the richest duck in all of Tralla La. Scrooge is suddenly back in the onerous position of supreme wealth that he was fleeing. Not wanting to experience the same pressures all over again, he hires Donald and the nephews to trek back to civilization and arrange with his pilots to have 100 plane loads of bottle caps flown in so that he will not be richer than anyone else. After a few weeks the first plane drops its bottle caps on the villagers. They are dancing around in joy when the second and third plane loads descend. Soon they realize that since everyone now has all the bottle caps they want,

they are totally worthless. What is more they are beginning to beat down their rice crops, pollute the lake, and cover the ground so that their sheep can find nothing to eat. They turn on the ducks, but Scrooge is able to save them by telling the villagers that the only way to stop the rain of bottle caps is to let them go back to civilization so that they can cancel the order. So with paradise lost and polluted, the ducks return once more to the conditions they have tried to escape.

Although the story was written more than 50 years ago, it can easily be seen as a parable for consumption in an age of globalizing consumerism. The natives of the less affluent world are seen to lust after novel Western goods, at least initially. Later they learn that these things not only do not make them happy, but they also cause them to lose the way of life that formerly brought them joy. Despite his enormous wealth, Scrooge is seen as unhappy with his life until he finds a mythical Shangri-La, which brings him contentment for a time. The bottle caps he brought with him turn out to be the equivalent of money and the source of the evil that he looses upon the valley. In the end, there is no hope for Scrooge to escape the rat race of the more affluent world and, despite his best intentions, he may have ruined the peaceful valley of Tralla La forever. Seen slightly differently, as Dorfman and Mattelart (1984) do in their analysis of the spread of imperialist ideology in Latin America through Donald Duck and Uncle Scrooge comic books, the ducks have brought the seeds of a capitalist exploitative economic system to a blissful communist society. But because the ducks leave Tralla La, the reader does not get to learn whether the outcome of this economic imperialism is ultimately good or bad.

For a glimpse at possible outcomes of unleashing Western-style consumerism on other parts of the world, two films invoking Coca Cola are relevant: Uys' (1983) *The Gods Must be Crazy* and Norbu's (2000) *The Cup*. In *The Gods Must be Crazy* it is a Coke bottle that falls from an airplane and it is found by !Xi, a !Kung bushman of the Kalahari Desert in Botswana. When he shows the strange bottle to others in his hunter gatherer society, they initially try using the bottle in their daily tasks of preparing food and producing bark cloth. But eventually the iconic bottle becomes,

2 global consumerism and consumption

like the bottle caps in Tralla La, an object of intense envy, lust, hatred, and violence. The sharing-based subsistence economy has been spoiled by the introduction of a nonindigenous good along with the implications of private property, materialism, greed, and the global consumer culture from which the bottle derives (*see* CONSUMER MATERIALISM). The only way to dispel this snake from the Eden of the Kalahari is for !Xi to take the bottle to the edge of the earth and throw it off.

The Cup is a rather different film about the introduction of Western things (a crumpled Coke can and television) into an unspoiled society (a Tibetan Buddhist refugee monastery in the Himalayas, not unlike Tralla La). The young monks in the film love soccer and as the film begins, they are playing the game using a crumpled Coke can as a ball. Coca Cola's iconic script is shown as a counterpoint to the prayers carved into mani stones and inscribed on the prayer wheels of the monks. The young soccer players scatter when a stern senior monk, Geko, appears. Geko picks up the can and brings it to the Lama who already has several reclaimed Coke cans on his altar serving as lamps burning clarified yak butter as a part of Tibetan Buddhist worship and prayers for the dead. Here, rather than the Western consumption object unleashing the ills of Western civilization on an innocent group of people, the foreign object is domesticated, localized, and incorporated into sacred rites. Just as the monks later accept soccer and satellite television, they have found a way to transform the profane, commercial, foreign object into a sacred, traditional, local good that accentuates rather than disrupts their spiritual lives.

Each of these stories presents a different take on the local consequences of global consumerism. We might well ask whether the outcome of globalizing consumerism is closer to the benign assimilationist scenario of the Tibetan Monastery or whether it is, instead, one of the more malignant disruptive versions seen in Tralla La or the Kalahari. What follows is a brief attempt to answer this question on the basis of theory and evidence.

GLOBAL CONSUMERISM

Global trade circuits like the Silk Road and the Spice Route are ancient and suggest that consumer goods have moved across cultures for some time. But several features make contemporary globalization different. The speed of transportation and technological developments mean, for example, that fresh strawberries can be had in most places in the world at any time of the year. More goods travel greater distances more quickly than ever before. Many of these goods are branded products and the multinational companies that market them make special efforts to promote them in local languages and media. Media has also globalized, however, and film, television, radio, Internet sites, telephone connections, magazines, news programs, and sporting events can now often have global reach (*see* GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES). These connections mean that we have windows on the world's consumption like never before. Japanese manga and American rap music not only cross the boundaries of their countries of origin, they also inspire local variations like American graphic novels and Japanese hip-hop culture (*see* GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES). Beyond the specific brands and program content that are globalizing and cross-fertilizing one another, the basic consumption ethos and the place of consumption in everyday life of people are changing as a result. Accordingly, we find Western-style shopping malls in Egypt, Christmas gift-giving celebrations in China, and Bollywood movies in Qatar.

One gloss for such developments is the advance of global consumerism. Consumerism, or consumer culture (*see* CROSS-CULTURAL PSYCHOLOGY OF CONSUMER BEHAVIOR), has been analyzed as having four defining characteristics:

1. A substantial portion of the population consumes at a level substantially above subsistence.
2. Exchange dominates self-production.
3. Consuming is accepted as an appropriate and desirable activity.

4. People judge others in terms of their consuming lifestyles (Rassuli and Hollander, 1986).

However, the first of these criteria may be too restrictive. Even for the poor of the world, the allure of consumer goods can sometimes be so strong that they are willing to sacrifice “necessities” in order to be able to afford “luxuries.” Examples include Romanians sacrificing eating in order to afford a refrigerator into which they cannot afford to put food, and Turks selling the milk-producing family cow to be able to buy candy for their children (Ger and Belk, 1996). Such practices have been referred to as *leaping luxuries* (Belk, 1999). Rather than simply see things as necessities or luxuries, a third transitional category is that of decencies – things like deodorants, feminine hygiene products, soaps, and hot running water. And as global communications promote world standards in such products, they also move from being seen as decencies to being regarded as necessities. Stearns (2002) suggests another criterion for a consumer culture to exist: deriving part of our identity from consumption objects; in other words, embracing a notion of the self extended through possessions. Together, at both the cultural and the individual levels, these criteria suggest a heightened consumption orientation in our lives.

By focusing on the broad attitudinal and value-based concept of consumerism rather than the mere fact of the proliferation of global brands and multinational corporations, we can see that the presence of global brands may or may not signal global consumerism. It also means that not only products but services also can be a part of this consumption orientation. And it means that the celebration of globalizing consumption holidays like Christmas may also tell us something about the interpenetration of global and local meaning systems. One possibility is that participation in global holidays provides a sense of shared global identity. Nevertheless, Belk and Kimura (2005) find that Christmas in Japan is localized and involves couples going out rather than families remaining in or returning to the home. Similarly, Yoko Brannen (1992) shows how Tokyo Disneyland has been adapted, domesticated, and made to fit within Japanese

culture, despite an outward insistence by the owners that the theme park be an exact replica of the one in California. This is done by both making the exotic park familiar (e.g., employees use the polite Japanese service voice rather than the more brash approach of Anaheim’s Disneyland), and keeping the exotic exotic (e.g., in park performances American, Chinese, and Korean characters are caricatured and made to seem totally other, even though Japan has undeniably been influenced by each of these cultures). Further examples can be found in the adaptations that McDonald’s has had to make for consumers in Asia (Watson, 1997). Rather than imposing a universal formula, the chain has had to alter menus, sacrifice quick table turnover, and realize that the restaurant can be seen by some as a significant fine dining experience reserved for special occasions and not simply a convenient place to get a meal. Global media have also had to adapt to local cultures. MTV had attempted to use a globalized approach in its Asian programming until Channel V began to localize for Indian audiences. It was so successful, that MTV was forced to do the same.

Discussions and theories concerning the effects of global consumerism have gone through several phases. The first involved theories of cultural imperialism as Western brands, entertainment, and media were seen as being imposed on the rest of the world (Dorfman and Mattelart, 1984). As we have seen, this thesis has not proven tenable, in part because consumers are active rather than passive recipients of marketing offerings. A second set of theories saw the reaction to global products, services, and media as producing a split between the West and the Rest. A variation of this theme sees the clash as being between the affluent minority and the poor majority. A third wave of theorizing saw the local as resilient and powerful enough to coopt, reconfigure, or reinterpret the global for its own purposes. A variant of this theme sees local businesses as able to use their cultural knowledge to out-compete global brand adversaries. If the cultural imperialist position erred on the side of seeing the consumer as too passive, resilient, and powerful, the local position likely sees the consumer as too active and empowered. A fourth perspective sees the globalization of consumption as fracturing into

a prism of global, local, and hybrid offerings with the latter creolized or glocalized fusions becoming the most common (Appadurai, 1996; Ger and Belk, 1996). Appadurai (1996), for example, focuses on the impacts of global flows of people, ideas, finances, media, and technology and the resulting disjunctures this creates in economies and cultures. Ger and Belk (1996) add to this list the changes and instability brought about by global flows of consumption objects that accompany these other mobilities. Since cultures constantly change and interact with each other, it seems reasonable to expect that certain intercultural elements will blend with one another in unique ways as they do so. Thus Wal-Mart, Ikea, and Carrefour are not so much spreading American, Swedish, and French culture throughout the world as they are mediating, combining, and reshaping cultures both in their home countries and abroad. A variation on this theme of dynamic hybridity is Wilk's (1995) notion of global structures of common difference. Wilk (1995) uses the example of the global spread of beauty pageants to suggest that, rather than resulting in any homogenizing outcomes, it is the structure of such competitions that is being globalized. In other words, the beauty contest and its focus on certain kinds of differences is diffusing globally, but this does not result in a hegemonic global standard of beauty. Global beauty contests instead spread the focus on structures of youth, race, ethnicity, and power guiding theses contests.

CONSUMPTION OF THE GLOBAL

One alternative to embracing global consumerism is the rise of nationalism (Ger and Belk, 1996). This was the case, for example, in Chinese efforts to resist the flood of global goods in Old Shanghai before communism. There is some evidence of a rise of pride in Chinese brands in contemporary China as well. And there is some evidence of contemporary Indian feelings of nationalism in resisting foreign brands and stores (Varman and Belk, forthcoming). Eventually, the distinction between global and local brands and stores may disappear. Watson (1997) tells the story of Japanese Boy Scouts visiting Chicago and discovering that America also has

McDonald's; and how, in Hong Kong too, most young people are unaware of the company's American origins. One of the reasons for this decline in recognition of globalism is simply habituation. First generations may recognize the entry of the global, but for subsequent generations, these origins are outside of their awareness. And even those Russians who are aware of the foreign origins of products like Coca Cola and McDonald's hamburgers may simply take them for granted and cease to think about their origins. A second reason for not attending the global is that with local franchises, joint ventures, and outsourcing, the distinction between what is local and what is global is blurring. Are Toyotas made in Canada any more foreign than Blackberry devices made in China? When companies on different continents merge, it becomes even harder to distinguish the local brand. At a more general level, what we in the West know as Chinese food is often not recognized as "real" Chinese food by Chinese visitors or immigrants. And as a part of a dynamic culture with various regional cuisines often fusing, Chinese food in China is also a changing category.

One of the reasons for the initial concern with resisting "cultural imperialism" in globalization and subsequent championing of the local was the feeling that something authentic is lost when we begin to replace local products and services with global goods. In Ritzer's (2004) view, the unique one-of-a-kind product is replaced by the interchangeable, dehumanized, and disenchanting commodity, or what he calls *nothingness*. There is both a romanticism and an elitism in this view. But to jump to the other extreme and claim that globalization is good for everyone would also be shortsighted. As with the opening of Eastern Europe after the fall of the Berlin Wall, one of the initial consequences of a flood of novel goods may be increased materialism. There is evidence that materialism is negatively related to happiness and feelings of well-being. Nevertheless, the direction of causality in this relationship is not entirely clear and Schudson (1998) argues that the desire for material goods may bring dignity and rationality to peoples' lives. But even if this is true for some people, those shut out of consumer culture by poverty may end up feeling even more deprived by

upsurges in global consumer culture. And at a more macro level, high levels of consumption fueled by globalism are likely unsustainable and harmful to the environment.

In the end, rather than seeking a Shangri-La free from global capitalism and global money or feeling that our way of life has been corrupted by the sudden arrival of a Coke bottle, we will very likely come to simply accept global production and consumption as the incontrovertible way of the world. Using Appadurai's (1996) notion of global flows, we can think metaphorically in terms of that most liquid of flowing substances, water. We are unlikely to view the water in our rivers and seas as being either local or foreign. It comes from somewhere and goes somewhere without bearing any traces of its origins or destinations. Granted when an iceberg shows up off the coast of southeastern Canada, it is recognized as coming from somewhere else. But the longer it is there, and the more it melts away, the less foreign it seems. And as for those bottles of Perrier, their claim of foreign origin is as much a matter of image as it is ownership. Perrier is now owned by the Swiss conglomerate Nestle, in any case. Other companies like Louis Vuitton remain French, but their products are no longer made in France. None of this is to say that globalism is inconsequential. The upsurge of globalism starting in the late twentieth century has resulted in some of the most sudden and profound economic shifts in the history of the world. The economic rise of China and other Asian economies are a dramatic evidence of these shifts. But from the perspective of Western consumerism and consumption, most of these changes were relatively invisible until the recalls of a number Chinese-made products in 2007.

A far greater and more sudden result of China's economic rise in the past 30 years is what is widely described as the country's *consumer revolution* (Davis, 2000). Part of this revolutionary rise of consumer culture has been the influx of foreign brands, stores, and advertising (Zhou and Belk, 2006). But much of it is based on rapidly rising incomes and a big push from the Chinese government to develop domestic consumption in order to reduce dependence on exports (Croll, 2006). However, not everyone has

benefited from these changes. Worker demonstrations have been common as state-run enterprises close down causing unemployment and breaking the once solid iron rice bowl of guaranteed employment. The cities, and especially the southern coastal cities of China, have benefited far more than rural areas and China's west. Even so, there remain many urban poor, and families in rural areas experience social upheaval when one parent goes off to work in the city for extended periods. The young are better able to adapt to the new economy than the old, and there is resentment between the new haves and the new have-nots of China (Croll, 2006). Even the "little emperor" children who are blessed with indulgence by parents and grandparents thanks to China's one-child policy, suffer as they become more obese and feel the added pressure of carrying the family's face. Few of these problems are unique to China, but they are made prominent by the rapidity of changes in Chinese consumption and the contrast to the days of Mao, the Cultural Revolution, and the Great Leap Forward. Chinese consumption bears close watching because it makes the effects of consumer culture highly visible as it shrinks the time period over which it unfolds and distills the best and the worst of global consumerism.

strategic export marketing – achieving success in a harsh environment

Constantine S. Katsikeas and Leonidas C. Leonidou

INTRODUCTION

The modern business environment is characterized by accelerating globalization, intensifying competition, and growing integration, which have been responsible for inducing an ever-increasing number of firms to embark on international operations (Kotabe and Helsen, 2001). As opposed to other more direct modes of foreign market entry such as franchising (see INTERNATIONAL FRANCHISING), joint venturing, and wholly owned production, exporting has been more widely adopted by manufacturing firms because it is less risky, more flexible, and less costly Albaumb and Duerr, 2008). In fact, exporting is the most popular, the quickest, and the easiest way for a company to become international, because it offers numerous benefits: it improves the firm's financial position, helps to transfer technologies and know-how from other countries, enriches managerial skills through exposure to idiosyncratic foreign environments, makes better use of production capacity, and facilitates organizational growth (Czinkota and Ronkainen, 2006).

The deployment of successful export marketing strategies constitutes a critical, and in many cases, a thorny process, which could assist in reaping the above benefits while at the same time avoiding the dangers involved (Leonidou, Katsikeas, and Samiee, 2002; Katsikeas, Morgan, and Kaleka, 2004). To be effective, such strategies should rely on a thorough analysis of the current situation, particularly focusing on the firm's resources and capabilities, the export task environment, and the foreign macroenvironment. It will then have to carefully target export markets through systematic foreign market selection, as well as through customer targeting and positioning. Following this, it is important to set achievable objectives that will enhance the firm's effectiveness, efficiency, and adaptiveness. Strategies for each of the elements of the marketing mix should subsequently be designed, with special focus on

the right degree of adaptation/standardization (see STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY). Finally, certain issues for organizing and controlling the exporting strategy should be examined.

EXPORT SITUATION ANALYSIS

As a starting point, the firm first needs to evaluate the existing situation with regard to its internal resources and capabilities, the export task environment, and the foreign business environment.

Company resources and capabilities. The firm's resources and capabilities are important prerequisites for achieving sound export marketing strategies (Leonidou, 1998; Leonidou, Katsikeas, and Piercy, 1998). Their analysis will reveal the strengths that are essential to support its exporting effort, as well as any weaknesses to be removed. With regard to *resources*, a major driving force is the specific interest and commitment of top management to exporting, particularly as regards the belief that export engagement is beneficial to the firm. Previous experience of managers in foreign countries and their special international marketing skills are two additional factors that safeguard the proper design of export strategies. Research and development represents a vital resource for exporting, especially when a firm has proprietary technical knowledge for unique products. The same is also true for production resources, such as the existence of modern manufacturing technology and the availability of adequate production capacity. Information resources are also crucial in building sound export strategies, especially if they refer to overseas market demand, foreign business practices, and export regulations and documentation. Finally, adequate funds to finance the export activity, coupled with the existence of a specialized export department to deal with international business, are also important to support export strategies.

On the *capabilities* side, it is very important for the firm to be able to identify business opportunities, such as locating and analyzing the potential of foreign markets, contacting prospective customers abroad, and acquiring specialized information for specific international projects.

2 strategic export marketing – success in a harsh environment

Another key capability is that of relationship building, particularly obtaining reliable representation in overseas markets and subsequently establishing and maintaining close relationships with foreign customers. Product-market development capabilities are also essential for building successful export strategies, since international markets provide a fertile ground for the adoption of new production methods, the development of innovative products, and the application of novel marketing techniques. A final point refers to the firm's capability to adapt to environmental changes, because the diverse and volatile nature of the foreign business environment requires a certain adjustment in the elements of the marketing mix.

Export task environment. The analysis of the export task environment will provide the exporting firm with crucial knowledge about the market, the buyers, the competition, and the marketing intermediaries (Leonidou, Kaminarides, and Panayides, 2007). These are forces directly affecting the firm's export marketing activities.

With regard to the *market*, the firm first needs to estimate the size of the market (both in terms of volume and value) in various foreign countries and determine its growth. It is also vital to define the structure of the market, since this will guide the firm to formulate its pricing strategies in the right context. Some other key issues relate to demand differences, demand seasonality, and demand elasticity, caused by variations in income levels, product images, and brand loyalty. Any barriers associated with entering (e.g., long geographic distances, trade barriers, and government regulations) and/or exiting (e.g., nonrecoverable investments, binding agreements with distributors, and personnel hired for a long period of time) foreign markets are also to be examined.

Apart from general foreign market characteristics, it is important to analyze the characteristics of foreign *buyers*. The habits and attitudes of buyers are not identical around the world, because of variations in topographic and climatic conditions, household size and structure, level of technical understanding, income level and its distribution, educational standards, manners and customs, and so on. Consumer buying roles

(e.g., decider, purchaser, user) also need to be examined since they differ across countries, and the same is true with regard to the purchasing power, shopping behavior, and usage patterns of end users. This is because all these lead to different product preferences, price acceptance levels, distribution systems, logistical support, and communication methods.

Competition is one of the most crucial components of the export task environment and, as such, it warrants special attention. Although the firm may enjoy a competitive advantage in the domestic market, when transcending national boundaries it may lose this advantage owing to more complicated, multiple, and intense competitive situations. The exporter should focus on the following issues relating to competition in international markets: origin of competitors (e.g., host country, home country, multinational), source of competition (e.g., same product market, related technology, substitutes), competing base (e.g., low cost, product differentiation, government protection), market position (e.g., leader, challenger, follower), and major strengths/weaknesses (e.g., financial, managerial, product).

The last component of the task environment concerns foreign *marketing intermediaries* (see INTERNATIONAL MARKETING CHANNELS), who help the company promote, sell, and distribute its products abroad. First, the exporter has to examine the structure and operation of the distribution system, since this implies adjustments in the way a product can be made available to the end user. Such adjustments should take into consideration the major actors in distribution, and the services they provide. The peculiarities involved in communicating effectively with end users in different countries necessitate an investigation into the availability of advertising agencies. Equally, it is useful to identify any research agencies that will help to provide timely, reliable, and accurate information about foreign market characteristics. Finally, the cost and quality of other types of marketing intermediaries, such as transportation/shipping firms, financial institutions, and mass media organizations, also need examination.

Foreign macroenvironment. The foreign macroenvironment consists of forces that are broad in nature, usually uncontrollable, and the source of opportunities to be exploited and threats to be avoided. However, as opposed to the domestic environment, the foreign environment is characterized by greater complexity, uncertainty, and heterogeneity attributable to the many different countries that comprise the international market. In evaluating the foreign macroenvironment, it is important to analyze its physical, demographic, economic, sociocultural, political-legal, and technological aspects (Leonidou, Kaminarides, and Panayides, 2007).

With regard to the *physical* environment, large geographic distances between the home and foreign markets and different territorial sizes among countries seriously influence transportation costs, product availability, pre- and postsales service, and product quality in the foreign market. Differences in climatic conditions also shape consumption patterns in each country and determine product/packaging requirements. The foreign country's natural resources are important in order to determine its wealth, as well as explore the potential to source raw materials for the company. The growing trend in many countries toward protecting the natural environment exerts pressure on the exporting firm to produce eco-friendly goods.

In the *demographic* environment, it is important to obtain information on the population size and growth of foreign countries, since these are key indicators of market attractiveness. It is also useful to know the age structure of the foreign country's population, as it is widely understood that consumers have different needs at various stages of their lives. The way the population of a country is geographically distributed largely affects the effectiveness and efficiency of certain marketing activities, particularly those relating to distribution, logistics, and promotion. Another demographic element that affects consumer behavior is the social class stratification of the population.

The *economic* environment consists of factors that affect consumer purchasing power, spending patterns, and living standards in overseas markets. Here, it is important to study per capita income and the way it is distributed

in each country, since this is inextricably linked to the size, quality, and potential of a foreign market. Foreign exchange rates and controls should also be examined largely, because they critically affect demand for the company's products abroad. Pricing strategies are greatly influenced by inflation rates (and price controls), which should be clearly identified in each country. The foreign economic infrastructure (e.g., road network, ports/airports, energy) also needs to be investigated, because it influences distribution methods, logistics costs, and promotional activity.

Understanding the *sociocultural* environment is crucial because it affects the basic values, perceptions, preferences, and behavior of the society. Differences in religion, values and attitudes, manners and customs, aesthetics, education, and social organization can greatly affect consumer behavior, targeting approaches, and marketing programs. This situation becomes more complicated in the case of countries with many subcultures and/or different cultural contexts. The exporter should also become familiar with the oral, written, and nonverbal aspects of the language used in a specific country, because these affect branding, labeling, and advertising decisions. Lack of familiarity with foreign business practices may place the exporter in a stressful situation, particularly as regards to building relationships with overseas distributors. For instance, while personal rapport is vital in conducting business in some countries, in others more formal procedures have to be followed.

The *political-legal* environment consists of government agencies, laws, agreements, and pressure groups that can seriously influence the firm's export operations. Foreign governments may impose a number of controls on exporters, such as entry barriers, price restrictions, and exchange controls that can turn the exploitation of export opportunities into a tedious, expensive, and prolonged task. Import tariffs may also pose a serious problem for the exporting firm, since they cause export prices to escalate, while nontariff measures (e.g., quantitative restrictions) may restrict the company's potential in overseas markets. Some of these markets are plagued by political instability caused by economic, societal,

4 strategic export marketing – success in a harsh environment

and/or political factors, which may seriously reduce strategic marketing effectiveness.

The last component of the foreign macro-environment refers to *technology*-related issues. A crucial point here is the level of technology used by buyers in the host country. This will affect product design, after-sales service, and communication modes. Understanding the prevailing communications technology is essential in order to achieve effective interaction with foreign partners, collect useful information from overseas markets, and design sound advertising strategies. Transportation technology is also crucial, because it affects the safe and speedy delivery of the products. Finally, the exporting firm needs to explore the degree to which information technology can be used, especially the Internet, because it has such a strong influence on the way the firm can communicate and sell its goods to middlemen and end users.

EXPORT MARKET TARGETING

Following the analysis of the internal and external situation, the firm has to select the most attractive foreign countries to enter, as well as define the target customer groups to supply to within each country (Majaro, 1982).

Foreign country selection. The exporting firm has to analyze various countries in order to *select* those with the greatest appeal. To this end, world markets should be systematically *segmented* based on a number of “macro” criteria, such as geographic location, market size, growth potential, cultural characteristics, stage in product life cycle, level of competition, and host government attitudes. This broad segmentation of international markets is essential to identify foreign country markets that could be easily accessible, approached in an effective manner, and yield adequate financial returns.

Having selected the countries that are most attractive as export destinations, the next step is to define the number of countries to be approached. Here, the firm has to decide about its *export market expansion* strategy, that is, whether to concentrate on only a few countries or to extend its activities to multiple countries (Katsikeas and Leonidou, 1996). While the former may help to better understand specific

customer requirements, establish and maintain long-term market presence, and maximize returns from individual markets, the latter can enhance product specialization, spread business risks, and result in greater flexibility. Since both strategies offer certain advantages (and disadvantages) for the exporter, the choice should depend on a number of contingent factors pertaining to the company (e.g., risk perceptions), the product (e.g., stage in life cycle), and the market (e.g., market stability).

The exporter has then to *prioritize* the countries it has selected to serve, and set the sequence and speed of entering each of them. In doing so, it has to take into consideration the availability of internal resources (e.g., financial, manpower, know-how), the attractiveness of the country concerned (e.g., market potential, level of competition, buyer sophistication), and the conditions of the global business environment (e.g., economic indicators, regulatory framework, technological change). It is also important to specify whether the firm should enter the market indirectly (i.e., selling through independent organizations located in the home country) or directly (i.e., selling directly to an importer or buyer located abroad). As opposed to indirect exporting, which is a low-cost and less complicated method of engaging in international sales activities, direct exporting allows for greater control and better exploitation of international markets.

Country target groups. Within each country selected, it is important to identify those market segments that are the most appropriate. Here, the exporter needs to *segment each foreign market* according to a number of geographic (e.g., region), demographic (e.g., age group), psychographic (e.g., life style), behavioral (e.g., product usage), or other bases that are considered particularly suited to a firm’s products. This exercise will reveal various segments that should be evaluated on a number of criteria, such as size/growth pattern, intensity of competition, and firm resources. It is essential to note that target segments may vary across countries, due to the existence of different stages of market development.

Having identified the segments within each foreign market, the exporter has then to *select*

the number of and set the sequence in which the segments need to be served. Here, the firm may either concentrate on a specific market segment (or segments) in a country using the same marketing mix, or adopt a differentiation strategy where each target segment is approached using a different marketing mix. The selection of the specific strategy will depend on a number of factors, namely availability of company resources, nature of the product, stage of product life cycle, degree of market variability, and competitors' market coverage strategies.

Finally, the exporter has to establish the *positioning* of its products in the minds of consumers in relation to competing brands. To succeed, it is important first to arrive at points of parity with the competition, identify areas with a competitive advantage, and choose those that are most promising to decide on the overall positioning concept. Most importantly, the firm needs to build its marketing mix around this concept, maintain the positioning chosen over time, and monitor market changes so as to make the necessary adjustments. Because of the diversity of overseas countries, the firm has to decide on whether to use the same positioning theme worldwide or tailor this to each individual market. While the former is more suitable in the case of catering to universal segments worldwide, the latter is more applicable when segments encounter cultural differences, legal constraints, and competitive forces across countries.

EXPORT OBJECTIVES

Having analyzed the current situation and decided on the targeting and positioning strategy, the exporter needs to set clear, measurable, and achievable objectives that will provide direction to the exporting strategy (Hibbert, 1985). First, the firm needs to establish its *overall export objectives*, such as export sales volume, export profits, and return on investment from export activities. Then, these objectives have to be broken down for each of the target countries selected, taking into consideration demand conditions, intensity of competition, and other market peculiarities. Finally, for each target segment within each country, it is important to determine specific objectives, such as market share, sales, and profitability. Notably, the

exporter should set not only financial but also nonfinancial objectives, such as those relating to the satisfaction, attraction, and retaining of customers.

Overall objectives should correspond to specific *marketing objectives* for each target market/segment, namely, those relating to product (e.g., new-product introductions), price (e.g., profit margins), distribution (e.g., distribution coverage), logistics (e.g., product delivery time), and promotion (e.g., brand awareness levels). In addition, the exporter should distinguish between strategic (e.g., deciding to use distributors in some countries, as opposed to agents in others) and tactical (e.g., selecting a particular distributor or agent within a specific country) objectives.

EXPORT MARKETING MIX

To achieve the firm's export objectives, a sound strategy has to be designed for each of the elements of the marketing mix (i.e., product, price, distribution, logistics, and promotion). Apart from achieving consistency, synergy, and synchronization among these elements, a key issue that needs to be addressed here is the degree of standardizing or adapting the marketing strategy in each of the targeted overseas markets (Cavusgil, Zou, and Naidu, 1993; Cavusgil and Zou, 1994). However, the decision to standardize or adapt the marketing strategy is situation specific, and this should be the outcome of a thorough analysis and assessment of the relevant contingency factors prevailing in a specific market at a specific time. In addition, the appropriateness of the selected level of strategy standardization/adaptation should be evaluated on the basis of its impact on company performance in export markets (see STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY).

Product. Different conditions of use, variations in purchasing power, dissimilar consumer tastes, and diverse sociocultural settings imply adjustments of the company's product *design and ingredients* to meet the idiosyncrasies of each foreign market. Moreover, in some countries, consumers are very *quality* conscious, thus requiring further improvements of the product.

Attention should also be paid to *branding* issues (see GLOBAL BRANDING: THREE KEYS FOR GLOBAL BRAND SUCCESS), since some brand names are difficult to pronounce and/or have some undesirable meaning or associations in certain languages. The special conditions involved in selling the product abroad (e.g., large geographic distances, rough product handling, extensive shelf time), coupled with the stringent safety legislation prevailing in some countries, requires more protective and safer *packaging*. Package appearance and size may also need adjustment, owing to variations in consumer preferences, disposable incomes, and shopping frequency.

With regard to *labeling*, legislation in most countries requires the provision of full information regarding product ingredients, nutritional value, production/expiry dates, and other elements, which have to be expressed in the local language(s). Certain symbols, signs, and colors appearing on the label may have to be changed to conform to local traditions, religion, and values. Differences in product use, availability of after-sales service, and competitive practices across countries necessitate changes in the nature and duration of the *warranties* offered for the goods exported. Finally, the provision of an *after-sales service* has to be adjusted in certain countries owing to different product usage, unavailability of spare parts, and poor capabilities of local firms to provide such a service.

Price. Offering satisfactory *prices* is key to attracting export customers, especially in light of the fierce competition that characterizes international markets. However, as opposed to domestic prices, export prices usually escalate because of additional costs incurred in modifying the product, its packaging, and service in overseas markets; higher administrative, operational, and transportation costs connected with exporting; extra taxes, tariffs, and fees imposed when entering the host country; and the higher cost of marketing and distributing goods in foreign markets. Certain unexpected factors, such as unfavorable foreign exchange rates, may make the company's prices even less competitive. Reduced competitiveness can also occur because of the higher cost of distribution,

logistics, and promotion abroad, adoption of dumping practices by overseas competitors, and foreign government policy to subsidize the local industry.

The exporter should also be cautious in quoting *sales terms* (e.g., cost, insurance, and freight) that are mostly preferred by foreign customers, as well as *credit terms* (e.g., 90 days letter of credit) that the industry in which it operates is accustomed to offering. Both sales and credit terms involve certain risks, which tend to be greater for foreign customers, who are much farther away, have no past experience with the company, and come from countries with unstable politico-economic environments. Another key aspect refers to the *currency* in which the export quotation is made, which has to be less vulnerable to foreign exchange fluctuations, and contribute toward making the company's prices attractive to overseas buyers.

Distribution. Obtaining *reliable representation* in foreign markets is one of the major challenges for achieving export success. It is very difficult to find foreign representatives who meet the structural (e.g., territorial coverage, financial strength, physical facilities), operational (e.g., product assortment, logistical arrangements, warehouse facilities), and behavioral (e.g., market reputation, relationships with government, cooperative attitude) requirements of the exporting firm. Once representation is secured, it is important to establish mechanisms (e.g., personal visits abroad, electronic communication, provision of financial incentives) to maintain control over middlemen abroad. Such mechanisms are imperative in export markets since there is greater dependence on the middleman due to binding legal agreements; it is difficult to find other middlemen in the overseas market as replacements; and the middleman carries other product lines that may be more profitable than those handled by the exporter.

On entering foreign markets, the exporter is usually faced with *distribution systems* that are different from those in the home market. Distribution differences are also likely to exist among international markets themselves. For example, as opposed to developed countries, developing nations are characterized by a higher per capita

number and smaller-sized retail outlets. Moreover, while in some countries, distribution channels consist of many layers, in others, direct distribution systems are more evident. Furthermore, the range and quality of the services offered by channel members vary considerably across countries. These variations imply that the firm's *distribution methods* have to be adapted according to the idiosyncrasies of each foreign market. The exporter should realize that, in some countries, access to distribution channels is not always available because they are already occupied by the competition, the length of the channel may be too costly to manage, or the power may rest with a certain distributor who controls entry at various levels of the system. To bypass this problem, the exporter can piggy-back on an already established distribution mode by another exporter who sells complementary goods, seek the assistance of export management companies, or set up its own distribution channels.

Logistics. Logistics (*see* DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES) is the element of the export marketing mix that requires immense adaptation, owing to the fact that products have to cross national boundaries, the multiple markets that the firm has to supply, and the peculiarities that these markets have with regard to their infrastructure. Beginning with the *ordering procedures*, the firm has to become familiar with the specific export documentation, shipping arrangements, and customs procedures required for sending its goods abroad. Ordering procedures for exports are generally more complicated than those for domestic sales, because they demand numerous documents, involve many parties, and incur high costs. Hence, it is important to have people within the company specializing in these procedures and/or to seek the advice of specialists in the field, such as foreign freight forwarders. The ultimate aim is to secure smooth order taking and execution procedures to satisfy foreign customers.

With regard to *transportation*, distances from foreign markets are usually greater than is the case domestically, thus involving greater risk of damaging the product, delaying

product delivery, and increasing transportation costs. This situation is even more critical in countries with large interborder distances, poor infrastructural facilities, and limited availability of transportation means. All the above factors increase transportation, insurance, and other costs associated with exporting, which are subsequently passed on to final selling prices. The exporter should be aware of the alternative modes of transporting goods abroad, as well as securing the best possible terms.

Finding adequate *warehousing* facilities in the host market is critical in ensuring a constant product flow, achieving timely delivery, and maintaining product quality at high levels. However, in some countries there are neither warehouses available to store the company's products nor proper installations to safeguard their quality. Storage fees may also be prohibitive in some countries, while in others warehousing equipment technology may be outdated. Storage problems become more acute in the case of countries where there is a large territory to cover and the consequent need for a multiple warehousing system to obtain satisfactory market coverage and support. The exporter can circumvent these problems by finding distributors with adequate warehousing space and technology and, if this is not feasible, by setting up its own warehouses.

The firm should handle its *inventory* policy with care in overseas markets, because transportation delays, demand fluctuations, and unexpected events can create shortages of its products. This is usually more critical when dealing with geographically distant countries, where it takes more time to resupply the market. Such a situation may involve a number of disadvantages for the exporter, such as (i) noncredible image of its products in the foreign market; (ii) lost sales and profits from potential and existing customers; and (iii) extra costs in trying to replace product shortages by using faster and more expensive transportation means. To accommodate this situation, the exporter has to put in place a sound inventory control system, which should take into consideration the territorial size, infrastructural facilities, and purchasing/consumption habits of each foreign market.

Promotion. Variations in buying motives, consumption patterns, and government regulations make it necessary for the firm to adjust its promotional activity to fit individual foreign market requirements. Of the elements of the promotion mix, *advertising* (see INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?) requires particular attention, not only because it habitually takes the lion's share of the promotional budget but also because of its greater sensitivity to the above differences. There are several specific issues in international advertising that need attention, namely, variations in the composition of the target audience; inappropriate content of the advertising message; unavailability or different use of advertising media; restrictions in the frequency/duration of advertising; and insufficient means of assessing advertising effectiveness. These factors are responsible for making adjustments in the advertising message, its execution style, and the media mix used across countries.

What is an effective *sales promotion* in the firm's home country is not necessarily equally effective in foreign markets. For example, in low-income countries there is greater appreciation among consumers for sales promotions, because they like getting something for free. Competitors in a foreign country may react negatively to specific sales promotions used by the firm, and may sometimes take legal action against certain methods used. In addition, the type and size of the sales promotion, in many countries, is regulated by foreign legislation (e.g., complete prohibition of competitions), while cultural factors may necessitate changes in certain sales promotions (e.g., nature of the gift provided). Finally, in some countries, retailers are not very cooperative as regards distributing and/or handling certain sales promotions (e.g., lack of redemption centers for coupons), thus making their use problematic.

Public relations is another useful promotional tool, especially when the exporter enters a foreign market for the first time and wants to create a favorable image and publicity. Public relations may also assist in cultivating good relationships with host governments, especially in countries where foreign business involvement

is viewed with suspicion. The nature of public relations should accord with the specific communication needs of each country. For instance, public speeches by the firm's managers may be more suitable in countries where relationships with government officials are important, while contributing to philanthropic events is more applicable to societies where there is distrust of foreign organizations.

Personal selling may prove particularly useful for the firm in the case of selling to countries where advertising and/or other promotional tools face legislative restrictions. However, personal selling is particularly culturally bound because it involves close personal contact and, as such, selling techniques and approaches have to be adapted to the character of each foreign market. Accordingly, the recruitment, training, motivation, and control of the sales force should fit the requirements of each country. Personal selling is particularly important in the case of exporting industrial goods, especially those that are highly priced, where explanations concerning technical issues and interpersonal relationships are vital to closing the sale (see GLOBAL SALES MANAGEMENT).

Finally, certain types of *direct marketing*, such as direct mail, telemarketing, and television marketing, may not be suitable for exporting to some countries, owing to poor communications infrastructure, high illiteracy rates, or incomplete/inexistent databases. On the other hand, the growing penetration of the Internet in many countries makes the use of electronic methods for contacting overseas representatives and end users an attractive option for the exporter.

EXPORT ORGANIZATION AND CONTROL

The effective and efficient execution of the export marketing strategy strongly depends on the existence of an adequate organization, and the way export activity is controlled, in order to keep strategy on the right lines (Branch, 1984; Nooman, 1985).

Export organization. To be able to coordinate and direct its foreign operations, the firm has to maintain a separate export department, staffed with adequate personnel, and managed by capable people. The presence of such a

department will give rise to continuous interest, motivation, and commitment within the firm as regards properly implementing the export marketing strategy. It will also help to carry out the specialized administrative tasks required to perform the exporting function, such as export documentation, handling of shipments,

and communicating with overseas customers. Moreover, it will help to make better use of the exporting skills available within the firm, as well as facilitate training on export-related issues. If the firm opts to operate in many countries, then it is important to divide the world market into regions and appoint managers for each region.

Table 1 Strategic export marketing plan overview.

| |
|---|
| Export situation analysis |
| – <i>Internal company analysis</i> – Identify the firm’s strengths and weaknesses in terms of export-related resources, capabilities, and other aspects |
| – <i>Export task environment</i> – Analyze foreign market characteristics, buyer behavior, competition, and marketing intermediaries |
| – <i>Foreign macroenvironment</i> – Investigate the physical, demographic, economic, sociocultural, political–legal, and technological environment of foreign countries |
| Export target marketing |
| – <i>Foreign country selection</i> – Select the most appropriate foreign countries, decide the number of countries to serve, and prioritize the countries to enter |
| – <i>Country target groups</i> – Segment each foreign market selected, identify the most attractive segments, and define positioning theme for each market segment |
| Export objectives |
| – <i>Country objectives</i> – Set overall objectives for each foreign country, such as market position, sales, and profits |
| – <i>Segment objectives</i> – Set specific objectives for each segment within each foreign market, such as market share, profitability, and customer satisfaction |
| Export marketing mix |
| – <i>Product</i> – Define export product design/style, quality, packaging, labeling, warranties, and after-sales service |
| – <i>Price</i> – Set export prices and end-user prices, sales terms, credit terms, and quotation currency |
| – <i>Distribution</i> – Establish foreign market representation, design channels of distribution, and set ways of managing channels |
| – <i>Logistics</i> – Design export order processing procedures, transportation methods, warehousing facilities, and inventory systems to serve foreign markets |
| – <i>Promotion</i> – Indicate actions for advertising, sales promotion, public relations, personal selling, and direct marketing in export markets |
| Export organization and control |
| – <i>Export organization</i> – Set up and staff the export department and assign geographic regions to specific managers |
| – <i>Export control</i> – Establish export-related standards, examine deviations from standards, and take corrective measures. |
| Contingency plans |
| –Indicate planned actions if events in foreign markets differ from those assumed in the exporting plan |

10 strategic export marketing – success in a harsh environment

Such geographic organization is useful in better introducing new products and services, building up distribution facilities, and training foreign sales representatives.

Export control. The firm should set up a mechanism for controlling the implementation of its export marketing strategy. First, clearly defined, easily understood, and commonly agreeable standards have to be set. These should relate to the stated exporting objectives, and be broken down for each unit and individual involved in the exporting activity. Exporting standards should take into account the specific conditions prevailing in the foreign countries targeted, such as economic situation, foreign exchange rates, and market characteristics. To establish the extent to which the various standards are met, it is important to obtain timely, reliable, and accurate information from various sources, such as internal records, strategic intelligence systems, and special survey reports. Finally, the exporter should be willing to take corrective measures, through, for example, a redefinition of the exporting objectives, a retraining or reassignment of personal roles, and the provision of more input, clarification, and guidance regarding various strategic aspects of exporting.

CONCLUDING REMARKS

To achieve success in international markets, the exporting firm has to carefully and systematically go through all steps of the strategic planning process identified earlier (for an overview of the major issues involved in each step see Table 1). As opposed to marketing strategies developed for the domestic market, export marketing strategies encounter more difficulties in design, implementation, and control. These can be attributed to (i) the stronger pressures exerted on the firm, caused by the demand of excessive company resources and specialized capabilities pertaining to exporting; (ii) the greater complexity involved, associated with the multiplicity, volatility, and heterogeneity of the international marketing environment; and (iii) the more acute business risks faced, resulting from geographic distance, fierce competition, and cultural differences in overseas markets.

Irrespective of these adversities, exporting firms should clearly understand that an export

market-driven strategy is of paramount importance to achieving high performance and long-term presence in a fast-changing, globalized world. Hence, the exporter should carefully monitor foreign market trends and buyer needs, establish an organizational culture geared toward offering superior value to customers, and engage specific resources and capabilities in satisfying customers better than the competition. All these are essential in reaping the numerous financial and nonfinancial benefits accruing from exporting, which, on the one hand, will help the firm to strengthen its competitive position in the domestic marketplace and, on the other, will encourage its gradual progression to more advanced stages of internationalization.

international pricing objectives and strategies

Matthew B. Myers and Marcel M. Zondag

INTRODUCTION

The price paid for a good or service represents the value the buyer places on the offering and as such price presents the one opportunity for a firm to capture customer value in tangible form and still meet its underlying goal of wealth generation. Price is recognized as a strategic tool as well as a dimension of tactical, day-to-day business decision making (Myers, 1997). In business-to-business dyadic relationships, price also acts as a relationship tool, an investment instrument of sorts, establishing trust and commitment between supply chain partners (Voeth and Herbst, 2006). On a different dimension, price functions as the vehicle of economic exchange, an integral part of the foundation and working of supply chains and, in turn, the entirety of the market economy system. Because of this multidimensional character, pricing decisions are a crucial factor in relationship marketing, that is, establishing and maintaining long-term, mutually beneficial business relationships with customers and with suppliers. The positive effects on firm performance of customer satisfaction and retention are widely recognized, so firms focus on creating a portfolio of situation and context specific relationships, allowing them to offer products and services that the customers will perceive as having a higher value than those offered by the competition (Golicic and Mentzer, 2006; Min, Mentzer, and Ladd, 2007). Price is therefore a crucial part of the integrated marketing mix as an expression of all dimensions of value: customers' perception, opportunity or switching costs, affective factors, and so on. Price provides immediate market feedback if the efforts for differentiation contained within all elements of the marketing mix have succeeded, and is the strategic lever in the marketing mix that, in return for a relative low investment, generates the highest, directly measurable returns. From a sample of Fortune 500 companies, Hinterhuber (2004) shows that a 5% price increases on average leads to a 22% increase in earnings

before interest and taxes (EBIT), a much higher impact than similar percentage increase in sales volume or reduction in cost would ever have. Price is thus the one element of the marketing mix that functions as both a marketing and a measurement tool.

In spite of its obvious importance, pricing is largely neglected in the marketing and global business literature. Specifically on the issue of international business-to-business sales, the subject of this article,¹ only a limited number of works can be found (see Table 1). In this article, we will first discuss the internal and external influence factors on a firm's pricing strategies overseas, followed by a discussion on pricing as a strategic value-management tool, before we conclude with some final thoughts on the lack of theory development and empirically sound research concerning international business-to-business pricing. We will see that because of the common emphasis on consumer and behavioral pricing theories, there remains a considerable "gap" in the body of knowledge.

THE PRESENT CONDITION OF GLOBAL PRICING STRATEGIES

Pricing, as part of the integrated marketing mix, presents a strategic level decision for managers. In turn, price is the opportunity for a firm to capture the hard-to-measure concept of customer value. Customer value is often expressed in terms of economic value, a construct that adds the price of the customer's best alternative product or service (the reference value) and the additional positive or negative value the customer places on those attributes of the firm's product or service that differentiate it from the so referenced product or service (Nagle and Holden, 1995, p.74). The economic value analysis presents the firm with the possible price level it can achieve. However, this is only part of the pricing strategy; cost, profit goals, and competitor pricing are other factors to be weighed in the process of determining the obtainable price range for a specific product or service (Hinterhuber, 2004). The wide variety of reference values found in overseas markets makes this an extremely important yet complex activity for global managers. Yet, the

Table 1 International business-to-business pricing studies.

| <i>Cite</i> | <i>Study/Topic</i> | <i>Results/Conclusions</i> |
|----------------------------------|--|--|
| (Myers, 1997) | Empirical study of US-based export managers Topic: Manager attitude toward pricing policies. | Owing to cost constraints and lack of communication and coordination between functional departments, international pricing policies are often ad hoc and cost-based only. |
| (Tzokas <i>et al.</i> 2000) | Empirical study of UK-based exporting manufacturers Topic: internal antecedents of firm orientation toward strategic export pricing. <i>Firm size is not considered as a variable in this study.</i> | Firms with a long-term customer focus and a positive attitude toward exporting tend to utilize “Strategic Export Pricing;” more formalized and centralized price management to maximize export returns. |
| (Myers and Harvey, 2001) | Empirical study of US-based exporting manufacturers Topic: internal and external antecedents of export pricing-control decisions. <i>Study conceptualizes a dynamic model.</i> | Larger, more experienced firm will maintain export pricing control over intermediaries, this is however not conducive to long-term export relationships; export pricing decisions should be made by entities closer to the customers. Export pricing decisions affect the strategic performance of the firm. |
| (Cavusgil, Chan and Zhang, 2003) | Empirical study of US-based exporting manufacturers. Topic: Firms’ Strategic Orientation toward Export Pricing (“SOEP”) | Classifying by SOEP, 4 firm typologies are recognized: (i) highly centralized experienced exporters, (ii) decentralized experienced exporters, (iii) new to export, and (4) experienced poor performers. Only the first two types of firms are successful as they adhere to a pricing strategy that matches their particular export environment. |
| (Bolton and Myers, 2003) | Empirical study of IT service contract customers in Asia, Europe, and North America. Topic: Price elasticity measured across market segments within national borders and across borders, influence of national/cultural preferences | Price can be used as a market segmentation tool; both vertical (country specific) and across borders on a regional <i>and</i> global scale as business customers are shown to have similar price elasticity across markets. |

|---------------------------|---|--|
| (Myers, 2004) | Empirical study of US-based exporting manufacturers. Topic: The effect of congruence or “fit” between export pricing strategy and venture strategy on firm performance | Not matching export pricing strategies with overall firm objectives, a common occurrence, will lead to suboptimal firm performance. |
| (Lancioni, 2005) | Propositional article Topic: Normative discussion about indus Empirical study of Portugal-based multi-industry exporting firms trial pricing. | In order to align pricing strategy with firm objectives a detailed procedure to formulate a pricing plan as integral part of the firm marketing plan is presented. |
| (Sousa and Bradley, 2008) | Topic: Internal and external antecedents of price adaptation and export performance. | Price adaption in reaction to environmental factors is common. Export experience and the number of markets serviced will lead to more rigid (centralized) pricing. Export performance is better in market environments which is much different from the home market. |

pricing decision, or pricing strategy, should be at the core of any industrial marketing plan (Myers, 2004; Lancioni, 2005). In many instances however, export pricing plans are mere derivatives of domestic pricing, sidestepping the intricacies of conducting international business and leaving firms with similar pricing and pricing structures across foreign markets (Myers, 1997). Because of the idiosyncratic differences between each export market, and even between individual industrial exchange relationships, many exporting firms end up underpricing, leaving “money on the table,” or overpricing, losing market share to local competitors. The latter also carries with it the risk of facilitating the creation of gray markets, the unauthorized transfer of goods from low-, to higher price markets, cannibalizing the firm’s revenues.

Before addressing these anomalies of the export pricing process, firms will first need to better understand the external and internal factors that affect their export pricing decisions. These are outlined below.

Factors external to the organization.
Understanding the global customer. It is a truism that a firm needs to understand who its customers are or, more so in the context of this discussion, the economic value customers attach to the firm’s offerings. Determining economic value involves measuring and interpreting the price effects of such diverse factors as alternative goods or services, budget restraints, switching costs, and a wide array of affective and cognitive evaluations that customers make in making their buying decision. Understanding the value perception of the customer will allow to approximate price sensitivity of different customer groupings, allowing for market and price segmentation (Bolton and Myers, 2003), or providing the benchmark for measuring the effectiveness of other marketing mix elements such as product (development) and promotion. It is similarly true that the geographic, regulatory, and cultural “distance” affecting cross-border transactions will add complexity to this information gathering process, leaving export managers with an incomplete set of

4 international pricing objectives and strategies

parameters on which to base their pricing strategies (Samli and Jacobs, 1993).

Although the industrial buyer fulfills a role not dissimilar to the individual consumer (Alderson, 1965), the actual industrial buying process differs greatly from consumer buying behavior; the decision is often made by groups of people (or decision making unit) to satisfy the needs and objectives of different constituents within the firm, the process is often more formalized than in consumer buying, and the personal and organizational risks associated with the purchase decision are often much greater than in the case of consumer buying (Moriarty, 1983). The majority of pricing research, however, is concerned with consumer buyer behavior and thus has little relevance and applicability in the field of international business-to-business pricing, and to a large extent our understanding of effective pricing to global customers suffers from a paucity of research in this area.

Heightened global competition. Establishing economic value is already an exercise in competitive analysis, comparing one's product and services against acceptable alternatives. The operating term here is "acceptable," signaling the need to include products or services in the analysis that may fall well outside of the often myopic view managers have about the positive attributes of their own products or services. As a consequence of this myopia, firms often find themselves facing unexpected competition, specifically in international markets where familiarity with competitors is limited relative to the knowledge of the competition in the home market.

Acquiring information about competitive products and pricing is mostly left to the sales force or, in the case of international business, to local distributors or sales agents and is therefore much less based on independent external sources than one would assume (Stottinger, 2001). There are two inherent problems with this practice. First, the sales function is mostly focused and rewarded on a firm's top-line sales and looks to set pricing as low as possible to book more sales, commonly mistaking "customer value" with "customer satisfaction," given that the latter will eventually increase if prices are low enough. Secondly, pricing intelligence

is often directly provided by the customers' purchasing staff, a business function that itself is looking to minimize prices, casting doubt on the validity of the data.

Diversity of overseas markets. Selling outside of the relative familiarity of the home market is wrought with logistical, regulatory, and cultural influences that most firms are ill prepared for. Certain jurisdictions may for instance levy high import duties, or restrict the free flow of goods for sociopolitical or protectionist reasons. Technical requirements and labeling laws may differ widely, increasing a firm's cost structure. Most firms try to minimize complexity by standardizing products, services, and business processes and will try to implement a uniform pricing policy across markets. As a result, firms select export markets and customers resembling their domestic market and customer, and do so in a more opportunistic manner than one would expect (Bilkey and Tesar, 1977; Kogut and Singh, 1988; Maignan and Lukas, 1997). As export experience grows, so does the firm's ability to make more deliberate pricing decisions. Before that, most price decisions are ad hoc adaptations of existing pricing, anecdotally driven. In order to circumvent the difficulties of exporting, smaller and/or lesser experienced firms often rely on export intermediaries such as stocking distributors in their exporting efforts. For these companies export activity essentially ends with delivery to the intermediary. With the exception of sales and promotional support, these exporters often leave pricing control to the intermediary (Myers and Harvey, 2001). This tendency to suboptimize export performance and revert to traditional pricing models is the result of a predominant internal focus of many firms when it comes to pricing decisions, discussed in the next section.

Factors internal to the organization. The importance of external information in the pricing process cannot be emphasized enough. The concept of customer value or "putting the customer first" is based on understanding the totality of customers' economic value, inclusive of all the competitive and environmental factors. Indeed, most firms are externally focused in

deciding on their integrated marketing strategy, but empirical research shows that firms still tend to focus internally when making pricing decisions, paying only lip service to value pricing (Nagle, 1987; Myers, 1997). Manufacturing cost, international sales costs, and profit margins as defined under accounting rules are the factors most influencing export pricing decisions (Solberg, Stottinger, and Yaprak, 2006). Most export firms use a cost-plus pricing model, adding desired gross margin to unit cost as determined by the accounting function and based on the firm's past expenditures. More experienced exporters do often pay more attention to the "voice of the customer" and operate a flexible cost-plus pricing model, making ad hoc pricing adaptations to counter competitive pricing, gain market share, or account for late payment, taxes, or fees.

Extant literature presents numerous other pricing strategies and tactics, often derived from traditional cost-plus models. The fundamental problem with using traditional cost accounting (or management accounting) for making pricing decisions is that it uses historical data to create a simplified representation of an inherently dynamic concept (cost per unit). For instance, price directly influences sales volume, which in turn should immediately affect the allocation of fixed costs to each unit downward (Nagle, 1987). More recent management accounting practices such as activity-based costing are still inwardly focused on cost instead on customer value and as such offer little improvement (Baker, 2006). Beside cost accounting practices, financial reporting standards do not allow for dynamic adaptation, and also entice managers with a seemingly sequential tabulation of pricing elements (costs and margin) that does not account for any relevant external market intelligence, and reduces the determination of customer value to an internal discussion (most often between the accounting and sales functions) about what constitutes a "fair" margin. The trends toward global standardization of financial reporting through the efforts of the International Accounting Standards Board (IASB) is not likely to change this, as historical cost remains as one of the prevalent basis for

financial reporting. We argue that this fundamental problem can only be addressed by a structural change in the formulation and execution of pricing strategy, requiring a shift in business philosophy toward value creation that may well extend to changes in organizational structure.

PRICING AS VALUE MANAGEMENT

Baker (2006), Nagle and Holden (1995), and Hinterhuber (2004) present persuasive arguments that internally focused or "cost-plus" pricing models often lead to suboptimal performance as firms seek to increase throughput at full capacity, thus reducing the cost per unit. However, recent events indicate that market success is not based on market share and size (see General Motors' loss of US market position) but on a firm's ability to generate continuing profitable sales by offering superior economic value. Achieving the highest level of "lean," efficient production throughput will have minimum benefits if throughput is of no economic value to the customers. Instead, the focus should be on the marketplace, looking to establish what products and services the firm can effectively produce that match the wants and needs of its customers as well as determining what the perceived economic value of these offerings are from the viewpoint of the customer.

The "power" of such customer focus is underlined by recent research (Bolton and Myers, 2003), showing how customers' price elasticity of demand transcends national borders, holding that pricing strategies can not only segment national markets (vertical segmentation), but also delineate market segment across national borders, (horizontal segmentation)—further evidence of the paramount role for pricing in the integrated marketing strategy.

All of this points to a relatively limited extant literature on the subject of business-to-business export pricing, creating a considerable "gap" in the body of knowledge.

"MIND THE GAP": ISSUES IN EXPORT PRICING PRACTICE AND THEORY

Despite repeated calls for more empirical research and theory building, export pricing, specifically industrial export pricing, remains

an understudied subject in marketing. Since *Industrial Marketing Management's* 2005 special issue on industrial pricing only a handful of scholarly works have been published. Intraorganizational transfer pricing, pricing controls, or consumer oriented single market issues seem to be more popular research subjects than intercompany export pricing. Following Solberg, Stottinger and Yaprak (2006), we agree that the many complicating organizational and environmental factors could well lead to this shortfall. Given today's hyper-competitive environment this is rather surprising, taking into account the immediate impact of price on export performance and profitability, and in the light of the prevalence of price-related globalization issues discussed in the popular business press.

In many cases exporting is more opportunistic than one would think or expect (Andersen and Buvik, 2002), and less the result of a well-executed strategic marketing effort. Because of the initial opportunistic character of export transactions, firms tend to have heightened expectations about the profitability of additional export efforts without sufficient appreciation for the complex, organization-wide impact of formulating and executing a truly integrated marketing strategy for creating and capturing cross-border customer value (Flint, 2004). In addition, in many cases firms reduce export sales costs by engaging export intermediaries, never establishing the dedication and business philosophy to manage export activities for maximum customer value and firm financial performance. Contrary to espoused commitment to long-term partnership with customers and suppliers, it is common for employee remuneration systems to be based on short-term financial goals, offering managers little motivation to pursue integrated long-term exporting strategies instead of taking a shorter term transactional approach. As a result, pricing in overseas markets to take advantage of customer values (as opposed to short-term profits) is rare. This often culminates in dysfunctional export business relationships. Irrespective of their purported financial success, these relationships are often perceived as stressful and risky, further diminishing the motivation for firms to achieve their full export

potential. Future research on the detriments of short-term pricing strategies on long-term export partnerships is needed to address the problems associated with extrapolating cost-based pricing models to overseas markets.

We argue that firms will need to institutionalize two key components to their global pricing efforts. First, firms often assume that the existence of an export (sales) function in an organization automatically denotes the ability to effectively gather and interpret market data (Myers, 1997; Hinterhuber, 2004), and/or the ability to deal with opportunistic behavior of one's foreign distributor (Cavusgil, Deligonul, and Zhang, 2004). Unfortunately, this is not possible without a concerted effort to gather market-related data which enables the effective setting of prices. The importance of gathering and interpreting (sense-making) such customer, market, and partner intelligence is further underlined by recent research, again confirming that an increase in economic value allows for proportionate price increase (Hulten, Vistrom, and Mejtoft, 2009), and often firms with export experience and suitably flexible pricing strategies achieve better export performance (Sousa and Bradley, 2008).

Second, firms must develop a strategic export pricing plan congruent with the overall firm-level strategic plan, that captures all necessary customer, competitor, and market intelligence and sets forth how the firm's pricing plans will contribute to attaining the firm's goals and objectives (Myers, 2004; Lancioni, 2005). In many cases executing such an integrative and dynamic pricing strategy will require organizational changes to facilitate sound pricing decision making, instead of ad hoc and intuitive adaptations of cost-plus pricing as a result of intraorganizational conflict between accounting and sales functions (Hinterhuber, 2004), for instance through the creation and empowerment of a corporate pricing function. While understanding the difficulties involved in these types of organizational changes, these shifts are often the only manner in which pricing plays a central role in export management and serves as a source for sustainable competitive advantage (Stottinger, 2001; Theodosiou and Katsikeas, 2001).

Against the backdrop of global business realities, it is clear why there have been repeated calls for timely and relevant export pricing research. Indeed, most international pricing research is descriptive, concentrating on specific price factors, industries, or geographical markets, resulting in findings of limited external validity. Findings are often cross-sectional, self-reporting surveys, raising questions about the causality captured in the conceptual models presented. The linkages between pricing strategies and export performance is often measured differently across studies raising questions regarding the validity of some of the research. Furthermore, integrative conceptual models (addressing multiple markets, industries, outcomes, and pricing strategies) are yet to be fully developed. One could argue that export pricing theory is (slowly) being developed “bottom up” as opposed to “top down.” On a more positive note, we consider it a valuable development that information gathering and knowledge sharing are becoming more prevalent in pricing studies. Also, we welcome the inclusion of the strategic, organizational, and human interaction aspects of export transactions in more recent empirical research and theory building literature. We do however feel that many of the rigor and relevance issues surrounding industrial export pricing research are a direct consequence of the considerable difference between espoused and actual pricing practices and a social/organizational desirability bias in the research measurements. When we more carefully review the successful global pricing strategies practiced by gold-standard marketing managers, we note that recipes for success are almost all based on creating and capturing superior customer value. In other words, as long as scholars provide a “quick fix” global pricing solution sets without accepting the need for a fundamental paradigm shift toward longer term, value-oriented pricing strategies, our understanding of the global pricing function will remain limited.

CONCLUSIONS

Pricing is the one marketing tool with the unique ability to indicate, dictate, and capture customer value. As such it plays a critical role

in the formulation and execution of export strategy. Firms (and scholars) should realize the “execution premium” (Kaplan and Norton, 2008) that is available from moving beyond traditional cost-based pricing methods and instead implementing a comprehensive information and knowledge acquisition strategy, leading to the formulation of a strategic pricing plan based on customer perceived economic value. Similarly, continuing consolidation, globalization, and transparency of markets will amplify the negative effects of not having a comprehensive, long term, value-based pricing strategy on the financial performance of exporting firms.

ENDNOTES

¹ We have limited our discussion to export pricing, more specifically, industrial (or B2B) pricing in cross-border transactions.

international marketing channels

Daniel C. Bello

INTRODUCTION

International marketing channels consist of interdependent organizations participating in business activities necessary to make a product or service available for use in markets around the world (Coughlan *et al.*, 2006). The structure or design of global channels can vary widely, comprising various organizational participants (foreign distributors, agents, subsidiaries, etc.) engaged in a diverse set of functional activities (selling to foreign customers, warehousing inventory, etc.) (Bello and Briggs, 2009). Channel designs range from completely integrated corporate channels (wholly owned subsidiaries) to closely managed partner networks (alliances; exclusive, highly cooperative middlemen) to loosely organized distribution systems (nonexclusive, arms-length middlemen). The mix of forces driving international channel design includes factors associated with the original equipment manufacturer (OEM or brand owner), channel members, and end users. Each of these key players – manufacturer, middleman, end user – places a unique set of requirements and constraints on the channel activity set – the business tasks and activities that must be conducted to provide value to end users.

Activity sets can be conducted within various channel designs, depending on the feasibility of governing-needed activities through institutional arrangements (IAs) such as contracting and ownership (Anderson and Gatignon, 1986; Zhao, Luo, and Suh, 2004). For example, a manufacturer's international channel may require that specialized warehousing, selling, and other unique activities be conducted in foreign markets (*see* DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES; GLOBAL SALES MANAGEMENT). What is the best channel design for these necessary channel activities? Should the manufacturer contract with a local public warehouse firm and sales agency, or should it establish and own a local subsidiary, using employees to perform these tasks? Issues of channel design reflect the relative ability of IAs to govern channel activity sets in

an efficient and effective manner (Bello and Zhu, 2006). Importantly, the feasibility of contracting, ownership, and other arrangements depend on the characteristics of the proposed activities and the institutional environments (IEs) of the home and host countries (Grewal and Dharwadkar, 2002). As will be shown, a complex interplay among firms, exchange characteristics, and IEs yields a set of feasible business activities and a workable channel design.

DETERMINANTS OF CHANNEL ACTIVITY SETS

Channel activity set refers to the marketing, logistic, and other business tasks and activities performed by channel participants during the process of making a product or service available for use. The value-added activities of a channel can be represented as marketing flows since work processes such as physical possession, ownership, and promotion flow forward through the channel, while others such as ordering and payment move up the channel from the end user (Coughlan *et al.*, 2006). Each basic work process involves many interdependent and costly tasks and activities. For example, in the flow of physical possession from factory to user, a host of warehousing, inventory, transport, and other logistic tasks may be necessary, each of which burdens channels members with direct costs, overhead, and business risk (*see* DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES). As Figure 1 illustrates, the many factors determining the particular set of tasks and activities that are conducted in international channels reflect manufacturer, middleman, and user needs.

A manufacturer's marketing positioning strategy, resource endowments, degree of internationalization (*see* INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?), among other factors, influence the set of activities necessary to move a firm's product and its title to end users. Marketing strategies based on product attributes run the gamut, extending from low-cost, utilitarian to high-quality, prestigious market positions; but, whatever a manufacturer chooses "the investments and activities required to realize the position must be specified" (Ghosh and John

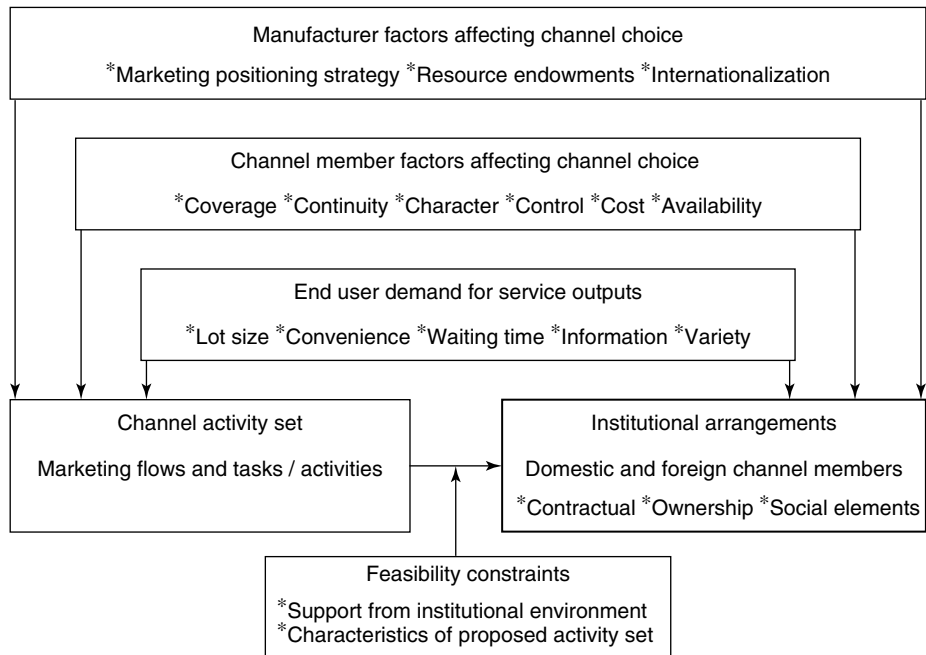

Figure 1 Determinants of international channel design.

1999, p. 143). For example, the specific activities associated with the promotional flow (*see* INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?; MARKET ENTRY AND EXPANSION) toward the end user differ substantially for prestigious versus utilitarian positions: the basic nature and type of personal selling, advertising, and sales promotion tasks required at the wholesale and retail levels are unique to each positioning. Likewise, the particular resource endowment of a manufacturer influences the activity set required to support the distribution of its products (Bello and Briggs, 2009). Firms with key patents, high brand equity, extensive partner networks, and other valuable resources and capabilities will require negotiation, promotion, and other business activities from channel members that differ substantially compared to the channel requirements of under-resourced manufacturers. As for a firm's degree of internationalization, a narrow domestic or regional focus relative to a broad global focus influences a firm's overall approach to international marketing, including

the particular tasks and activities required of domestic and international trading partners (Czinkota and Ronkainen, 2007).

The channel members available to participate in a manufacturer's distribution system also influence the particular mix of activities that can and will be conducted (*see* INTERNATIONAL TRADE INTERMEDIARIES). For example, a multinational corporation (MNC) may target rural, lower-income Filipino consumers, though it may lack the necessary capabilities to self-perform promotion, logistic, and payment collection tasks for this difficult-to-serve user segment. Given its resource shortcomings, the manufacturer may prefer a competent distributor as its local channel partner; yet, local distributors with the necessary sales coverage, cost structure, and complementary product lines may simply not exist. These types of channel-member factors have been summarized as the C's of international middlemen (Czinkota and Ronkainen, 2007): their coverage, continuity, character, control, cost, and so on. Thus, manufacturer factors may call for a foreign distributor, but local middleman factors may discourage this

choice, leading the firm, perhaps, to use a local sales agent supplemented by a corporate market development manager for the country.

End-user demands for channel services are often the most important drivers of required channel activities, since the ultimate success of any distribution system hinges on its ability to deliver value to the final customer (Coughlan *et al.*, 2006). As benefits for the end user, channel service outputs satisfy how users prefer to shop and reflect their purchase preferences and patterns. Essentially, user service demands answer the question "Besides the product itself, what is it that end users want from the buying process?" Users tend to prefer a specific mix of channel services such as lot size, spatial convenience, delivery or waiting time, product/brand variety, product information, after-sales services, and so on. Different segments of end users may demand substantially different channel services. Compared to their urban, high-income countrymen, rural, low-income Filipinos may require a smaller lot size (single-serve packaging), retail within walking distance, no waiting time (due to an absence of household inventories), but less brand variety and after-sale services, and so on. To target both segments of Filipino consumers, an MNC must develop different channels, each capable of performing business tasks necessary to satisfy the mix of services demanded by each customer type.

INSTITUTIONAL ARRANGEMENTS

Regardless of factors driving a channel's activity set, the resulting mix of tasks and activities to be performed can be organized and managed within a variety of alternative channel designs (Anderson and Gatignon, 1986; Zhao, Luo, and Suh, 2004). Since channel members differ in cost efficiency and task effectiveness, they tend to specialize in performing activities yielding channel designs where a member participates in one or more flows but not in others (*see* MARKET ENTRY AND EXPANSION; STRATEGIC EXPORT MARKETING—ACHIEVING SUCCESS IN A HARSH ENVIRONMENT). In the case of a direct channel, a manufacturer with a subsidiary may participate in physical possession (operates

foreign warehouses), ownership (retains title), and promotion (manages local sales force) in the foreign market. In the case of indirect channels, a manufacturer, when using foreign sales agents, may only relinquish selling while continuing to retain title and local warehouses; when using foreign distributors, a manufacturer would not participate in these flows since it sells the product to a local merchant middleman who holds title and performs local logistic and sales activities.

The allocation of tasks across firms in a channel reflects the IAs employed to ensure that participating firms conform to channel requirements by binding parties to their role responsibilities, guaranteeing economic returns for channel participation, and motivating cooperation (Bello, Lohtia, and Sangtani, 2004). IAs are the contractual, ownership, and social elements necessary to support the performance of the channel activity set within a channel design (Carson *et al.*, 1999). By establishing the rules of exchange, IAs encourage coordination and determine a division of gains sufficient to motivate all firms to participate in their assigned channel flows. In ongoing distribution systems, it is the contracts, ownership, and social forces that induce sufficient cooperation among self-interested firms to ensure each independently implements the investments and activities required to deliver value to end users (*see* INTERNATIONAL RELATIONSHIP MARKETING; MARKETING STRATEGY IMPLEMENTATION).

Feasibility constraints. As noted in Figure 1, the feasibility of managing channel activities through contracts, ownership, and social elements depends on the characteristics of both the proposed activity set and the IE in the home and foreign market (Carson *et al.*, 1999). While value-added activities can occur within a variety of direct and indirect channel configurations, distribution activities are always conducted through exchange transactions between a principal (actor needing an activity to be conducted) and an agent (actor conducting an activity). An OEM principal requiring local selling and delivery for its product in a foreign market may use a corporate hierarchy or subsidiary (ownership element of the IA): in such direct channels, the principal engages in

an exchange transaction with a subsidiary-based employee-agent, the actor conducting the activities in the foreign market. Alternatively, the principal may use a market-based exchange with a foreign distributor (contract element of the IA): in indirect channels, the principal's exchange transaction occurs within a competitive market since the distributor-agent in this case is selected from among several alternative, independent merchant middlemen available in the foreign country (*see* INTERNATIONAL NEGOTIATIONS).

Characteristics of the activity set. Much theorizing has focused on determining which element of an IA – market contract, hierarchical ownership, or social/relational – is best suited to govern exchange transactions for global distribution activities (*see* Bello and Briggs, 2009). While various theories provide important insights to channel design, transaction cost analysis (TCA) is the dominant paradigm for analyzing institutional structure and the efficient organization of business activities (Rindfleisch and Heide, 1997, Williamson, 1996).

TCA employs an economic efficiency criterion for channel design: efficient IAs minimize the transaction costs associated with conducting activities by aligning the attributes of exchange with the governance abilities of alternative IA elements (Bello and Zhu, 2006; Williamson, 1996). Transaction costs are the costs of managing an exchange transaction, including *ex ante* costs (drafting and negotiating agreements) and *ex post* costs (monitoring and enforcing agreements) (Rindfleisch and Heide, 1997). In other words, “TCA logic focuses on the characteristics of exchanges involving distribution activities because, given the potential of partner opportunism, exchange attributes may give rise to the governance problems of safeguarding specific investments, adapting to change, and evaluating performance” (Bello and Briggs, 2009, p. 398). A principal-agent exchange is characterized by high transaction costs to the extent a channel activity (i) requires specific, rather than general, assets, (ii) is subject to unanticipated changes in future circumstances (environmental volatility), and (iii) involves performance ambiguity or difficulty in assessing task outcomes (internal uncertainty). Specific

assets create safeguarding problems since an investor becomes locked in to the relationship: investments dedicated to a channel partner have little value in alternative uses, subjecting the investor to exploitation of profits by an opportunistic partner. Environmental volatility causes adaptation problems by creating unanticipated opportunities for a partner to exploit change by opportunistically renegotiating terms of trade. Performance ambiguity gives rise to measurement problems, making it difficult and costly for a principal (or a third party such as a court) to evaluate whether the agent's conduct is in compliance with agreements.

High transaction costs impose significant constraints on the feasible IA elements capable of efficiently governing the principal-agent exchange for an activity. For example, a manufacturer developing a foreign market may require specialized warehousing (unique material handling, special temperature/humidity control, etc.) for its product, and may prefer to address these needs by contracting with a local public warehousing firm (*see* DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES). However, high transaction costs make this channel activity noncontractible since a local warehousing firm contemplating modifying its warehouse to service the manufacturer would be exposed to safeguarding and adaptation problems that are inadequately solved through simple contracting. First, specialized warehousing investments only have value in the service of this specific principal, making the warehousing firm vulnerable and unable to retaliate against bad principal behavior because of its lack of alternatives. Hence, profits or economic rents from the warehousing firm's investments cannot be guaranteed by a contract since (i) during the contract term the principal can exploit the agent (extra demands, slow payments, etc.) because of the agent's locked-in situation, and (ii) upon expiration the principal may opportunistically demand unfair terms to continue the relationship. Second, the market-development effort may prove volatile, failing to provide the steady volume necessary to operate the warehouse at capacity, saddling the warehousing firm with unexpectedly high costs and no profits. Given these characteristics, a simple contract does not solve the warehousing

firm's safeguarding and adaptation problems in a manner sufficient to induce participation in the manufacturer's channel system.

While high transaction costs create contracting difficulties, low transaction cost situations are easily governed through simple contracting (Williamson, 1996). A manufacturer requiring general warehousing (employing common, industry-standard assets) for a product with a proven sales record in a foreign market will encounter little difficulty in contracting with a local warehousing firm (*see* DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES). Low transaction costs evidenced by the lack of safeguarding and adaptation problems make this channel activity easily contractible. With a simple contract, a warehousing firm can confidently participate in this manufacturer's channel system. In contrast, the manufacturer requiring specialized warehousing must motivate participation by offering increasingly complex contracts, perhaps addressing safeguarding issues through clauses guaranteeing renewal at attractive terms or addressing adaptation problems by guaranteeing minimum payments regardless of volume. At some point, however, patching together complex clauses fails to motivate participation since governance problems remain unresolved.

The contractible subset of the channel activity set is composed of channel activities subject to contractual solutions to governance problems (Carson *et al.*, 1999). For noncontractible activities, the IA element of ownership may be better aligned with the governance problems characterizing these principal-agent exchanges. The manufacturer requiring specialized warehousing may have to own the unique material-handling and humidity equipment located at the foreign facility, and be responsible for repairing and maintaining the assets it owns in the warehouse. In other words, the warehousing firm's participation is obtained by devising a suitable IA for each aspect of the physical possession flow: a five-year contract for the contractible activities (leasing warehouse space) and manufacturer ownership of noncontractible activities (specialized equipment). Such ownership rearrangement of high transaction cost activities reflects the TCA prescription of market governance (contracting) as the default IA for nonproblematic activities,

while hierarchical governance (ownership) is used to efficiently address exchanges posing serious safeguarding, adaptation, and measurement problems (Rindfleisch and Heide, 1997).

In this way, an appropriately designed IA is necessary for every aspect of the channel activity set (Bello and Zhu, 2006). In terms of the promotion flow (*see* INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?), for example, a manufacturer may decide to sell a complex, technical product in a foreign market. What is the appropriate IA for the foreign selling activities? If the principal-agent exchange for the local selling effort invokes few safeguarding, adaptation, and measurement concerns, a simple contract with a foreign sales agency is the efficient channel design. However, owing to its inherent complexity and frequent innovations, if the product requires specialized learning to sell effectively, a sales agency may be reluctant to invest in extensive and continuous training (a specialized human asset, nonredeployable to other principals). Fearful of lowered commissions or even termination after it develops the foreign market for the product, the sales agency may decline participation in the channel, worrying that economic return from its investments cannot be sufficiently guaranteed through a contract. The manufacturer may find it necessary to bring the selling task in-house, establishing a sales subsidiary, and training its own salespeople.

Social elements (informal rules such as relational norms) are the final IA mode, which are most effectively employed for activities subject to difficulties in both contracting and ownership (Carson *et al.*, 1999). Since relationship norms (*see* INTERNATIONAL RELATIONSHIP MARKETING) employ social enforcement to bind parties to their channel activities, difficult exchanges can be governed by certain relational norms (Bello, Lohtia, and Sangtani, 2004). As shared understandings between the parties, norms such as information sharing (willingness to exchange proprietary information), flexibility (willingness to adapt procedures), and solidarity (desire to maintain relationship) can enforce compliance to social expectations regarding

assigned activities. Returning to the specialized warehouse example, repairing and maintaining unique material handling and humidity equipment may involve tacit knowledge that is so causally ambiguous and embedded in the manufacturer's corporate routines that it cannot easily be transferred to the foreign warehousing firm. What kind of IA can best govern the costly and difficult maintenance of the manufacturer-owned equipment in the leased space of a foreign warehouse? While manufacturer technicians (ownership) can periodically visit the facility, repair and maintenance requires a great deal of information sharing, flexibility, and solidarity by the partners to make such visits timely and effective. Without strong relational norms, the contractual and ownership elements by themselves may not be adequate to sustain the specialized foreign warehousing activity for the manufacturer's international channel (*see* INTERNATIONAL RELATIONSHIP MARKETING).

Support from the institutional environment. As macrolevel aspects of society (*see* MARKETING ASPECTS OF PSYCHIC DISTANCE; MARKETING ASPECTS OF CULTURAL DISTANCE), the IE consists of underlying and distinguishing elements of a country's setting and context (Bello, Lohtia, and Sangtani, 2004). Theorists (Scott, 2001) recognize three elements composing the IE: regulative, normative, and cultural-cognitive forces. Importantly, differing IEs around the world (*see* BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS; EMERGING MARKETS) moderate the ability of exchange partners to develop the IAs necessary to support a desired channel activity set. A host country's regulatory, normative, and cultural-cognitive profile will either enhance or inhibit the ability of a foreign manufacturer and local middleman to craft the contractual, ownership, and social elements needed to allow the conduct of channel activities (Grewal and Dharwadkar, 2002). Importantly, a host country's IE may be inadequate or fragile, unable to support IA elements necessary to guarantee economic returns to firms for participating in the channel's activity set. In other words, not every proposed international

distribution venture can be conducted; some deals simply cannot be done owing to poor IE support for the type of IA necessary to motivate participation by the appropriate parties (Carson *et al.*, 1999).

The *regulative* element reflects the demands of government bureaucracies, courts, and regulatory bodies to comply with laws and other country-specific rules or requirements (Bello and Briggs, 2009). By imposing constraints and penalties as well as providing inducements (subsidies, tax and tariff concessions, etc.), the legal and regulatory mechanisms in a country strongly influence the feasibility of IA elements to provide the guarantees and economic incentives necessary to secure participation. For example, a US manufacturer may experience little difficulty with its domestic channels in developing contracts with complex clauses detailing cost-plus, take-or-pay, or other pay-for-performance agreements. Ease of contracting in the United States reflects a strong regulative IE due to legal devices such as the Uniform Commercial Code, and because its "independent judiciary strengthens the predictability of the law and makes contract enforcement easier ... this enlarges the scope of contracting possibilities" (Carson *et al.*, 1999, p. 119). In contrast, some developing countries (*see* EMERGING MARKETS) in Eastern Europe, Asia, and elsewhere lack the comprehensive legal mechanisms, judiciary, and political system necessary to guarantee just and impartial enforcement of contracts. Likewise, because some countries do not strongly enforce property rights, especially for nominal foreign owners, the IA of ownership may not be supported, making certain channel activities infeasible as they are unable to be confidently contracted or owned. Hence, a US firm's market-entry plan for certain foreign markets may be abandoned as impractical because of IEs that are incapable of supporting the required channel activity set.

The *normative* element refers to a society's norms and values that direct behavior through social obligations and expectations, prescribing how actors are to behave, and defining legitimate business practices (Scott, 2001). Consequently, a foreign manufacturer may be unable to motivate the participation of local firms because the required contracting, ownership, and social

elements of the proposed IA are inconsistent with the country's work style and concepts of legitimate business arrangements (Bello, Lohtia, and Sangtani, 2004). For example, domestic Japanese firms tend to respect traditional practices and hold strong loyalties to local partners, making them suspicious and unresponsive to foreign firms making what appear to be highly unconventional and risky business propositions. Owing to mimicking traditional behaviors and internalizing legitimate codes of conduct, potential Japanese partners may object to contractual, ownership, or social aspects of a foreign manufacturer's proposed channel activity set. As a result, the foreign firm may find its market-entry plan for this country impractical because of poor support from normative elements of the IE.

The *cultural-cognitive* element refers to socially constructed, common frames of meaning that achieve compliance by providing people in a country with "prefabricated organizing models and scripts" (Scott, 2001, p. 51), making other types of behavior inconceivable. Cultural control over behavior is habitualized, yielding a collective programming of mind and actions that may or may not support aspects of a proposed IA (see BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS). Culture is embedded in the perspective of local channel members, impacting their willingness and ability to participate in contracting, ownership, and social aspects of a channel arrangement proposed by a foreign principal. In Japan, culture uniquely supports *keiretsu*-based bonds among local firms that often inhibit a potential Japanese partner from accepting an IA proposed by a firm outside the group. In China, *guanxi* or strong personal connections are often necessary to develop business arrangements. Without the requisite *guanxi*, a foreign manufacturer may find it difficult to craft the necessary IA elements, regardless of the apparent economic and strategic benefits of its proposed channel activity set for the Chinese marketplace (Bello and Briggs, 2009).

To conclude, international marketing channels are one of the most complex and dynamic aspects of global marketing. Cross-border channel arrangements are the result of multifaceted interactions among firms, activity sets,

and IAs. Feasible channel designs reflect a compromise among the competing demands of these factors and the constraints associated with the prevailing IE. Clearly, careful analysis and keen managerial judgments are necessary to achieve the most productive balance among the many determinants of international channel design.

international retailing

Brenda Sternquist

The 1990s has been an era of consolidation and internationalization for major food retailers (Sternquist, 2007). CIES, the Food Industry Forum, conducts an annual membership survey. Internationalization of retailing was one of the top three issues for 1998 and continues to be a major industry interest. We know little about globalization of the retail industry. We are used to analyzing globalization in manufacturing, but retailers have stayed home, until now.

Manufacturers are interested in retail internationalization. They want to know how to deal with their retail customers who buy, not on a country to country basis, but on a regional or global basis. Global/Multinational retailers have the capacity to bring about regional, and possibly world, price convergence. Global-NetXchange (GNX) is an international Internet sourcing system sponsored by Sears, Carrefour, Kroger, Metro, Sainsbury, Coles Myer, and Pinault-Printemps-Redoute. Sainsbury has used this system's reverse auction reducing the bidding process from 6 weeks to just a few hours. Sainsbury anticipates purchasing 75% of their goods through GNX.

There has been very little theoretical development leading to an explanation of how, why, and where retailers internationalize. Internationalization theories that are developed to explain manufacturer's internationalization have limits when applied to retailing. Most theories of internationalization begin with the assumption that the company has an export option but retailers do not have an export option. Since the retail function is one that requires sale to an ultimate customer they must have a physical presence in the country to be a retailer. This presence might take the form of a website in the case of an Internet retailer, but it is a presence.

Two major problems have limited the development of a comprehensive theory of retail internationalization. The first limit is that most researchers have assumed that internationalization is the same in all types of retailers. Salmon and Tordjman (1989) were the first to identify two different types of retailers that they termed *global* and *multinational*. However, other than

Sternquist (1997a) major researchers have not followed this designation. Instead, all types of retailers are put together for analysis. There are at least four different types of retailer internationalization (investment, pure franchisor, global, and multinational) each with a different expansion pattern, partly because of the way the company is organized, but there are other factors that also influence internationalization choice. Therefore, differentiation of retailer types helps to distinguish how different retailers internationalize. The second major problem is that most researchers have observed only retailer's successful international moves without analyzing the actions that are not successful. It is essential to analyze the internationalization failures in order to fully develop a model of successful retail internationalization. Failures are important because companies are more likely to analyze failures rather than success. Also, failures represent the definitive answer about whether an expansion pattern is correct.

TYPES OF RETAIL INTERNATIONALIZATION

Investment. Investment refers to purchasing an existing well-managed company and allowing management to continue operations. This is a dormant type of management. This is the strategy used by Delhaize, Ahold, and Sainsbury when they first entered the United States. Investment also appears to be the strategy used by Wal-Mart in their purchase of ASDA (UK). Dave Ferguson, president and CEO of Wal-Mart Europe said, "We've got a company that we were smart enough not to try and change" (ASDA, 2001). Companies using investment strategy are looking for (i) higher than domestic return on investment, (ii) a safe foreign international investment environment and/or, (iii) access to retail know-how. The motivation for purchasing companies in other countries rather than the home market is to diversify the company's investment. Delhaize purchased Food Lion in the United States at the height of the cold war. They wanted the chance to put company resources in a more stable geo-political environment.

Internationalization through investment leads to little knowledge transfer, and therefore it does not necessarily lead to more active models of

management in the company's internationalization. Investment is also an expensive internationalization strategy because the company is buying a well-managed company, rather than a company in trouble, and are therefore paying top dollar for this investment, which makes the return on the international investment difficult to recoup. Ahold sought the "gem" retailers in each country they entered. If they could not purchase the country gem they would not enter the market. We can see from the recent disposal of Ahold acquisitions in South America and Asia that the investment strategy is difficult to pull off.

Pure franchisors. Another form of dormant management is a pure franchisor. These companies use franchising exclusively in their international expansion. Pure franchisors typically focus on master franchising networks given to individuals on a countrywide basis. Pure franchisors typically expand internationally for opportunistic reasons. Opportunistic means that someone approaches the company with the idea for a franchise, rather than the company developing an interest in the country for strategic purposes. For instance, the McDonald's Japan master franchise was given to an entrepreneurial handbag/shoe salesman having an account at Mitsukoshi. He convinced the McDonald's corporation that their burgers and fries would be a hit in Japan. At that time McDonald's was not interested in opening company stores in Japan. For master franchisors the identification of a great person to develop the network is more important than identifying the best country to enter. For this reason, when one views the expansion pattern of master franchisors, it is of a random variety of countries rather than a stages type of expansion where a company sequentially enters culturally similar countries.

Both investment and pure franchisor internationalization are based on dormant management. Because management is dormant there is little knowledge transfer. Also, from a retail strategy standpoint, neither method is a strategic retail decision. Both of these options are financial decisions that do not lead to further international expansion in a predictable way. It is important to identify these two motivations for international expansion because retailers using these approaches need to be excluded from modeling

the internationalization of retailers as they are not strategic and rational, but rather opportunistic and random. Events that are random cannot be successfully modeled. In other words, you cannot take their experiences into consideration when developing propositions that will explain internationalization.

Two types of retailers whose moves can be considered strategic are focused on here. The terms initiated by Salmon and Tordjman (Sternquist, 2007), namely, global and multinational retailers, are used. The terms *global* and *multinational* do not indicate their degree of internationalization; instead they refer to the concept of standardization (global) versus adaptation (multinational). There is controversy about these terms. In the marketing literature, multinational firms are often referred to as multi-local. But this concept does not convey the idea that multinational retailers learn from each international movement and this knowledge is important in determining future international actions. Not every retailer can be classified as a totally global or a totally multinational retailer. Most retailers have some characteristics that cross over, but we can see some patterns when we use this designation.

Pellegrini (1994) presents an important distinction to explain paths for growth. He identifies the search for growth related to (i) an attempt to extend the application of the firm's proprietary know-how to get the benefits of internationalization; this is called *rents* in the management literature; (ii) an attempt to optimize the scale of operations (economies of scale); or (iii) an attempt to expand the mix of operations (economies of scope) to reduce costs and increase efficiency. In the next section the paths for growth for global and multinational retailers are considered.

Global. Global retailers are centralized, standardized, and generally small format retailers. These retailers are often vertically integrated, frequently focusing on private label or exclusive merchandise. Examples of global retailers are Zara, Mango, and Gap. They do not change their retail offering much when they enter foreign markets, but they look for a universal, global market segment that will accept their retail offering. Since these retailers are relatively

small in scale and centralized, it is possible to develop business format franchises for the system. Because they have a standard format, they can be replicated very rapidly in new locations.

Global retailers begin their internationalization not to countries, but to world class cities where they expect to find a segment of consumers that are indistinguishable throughout the world. They do not need to change their offering because their consumer is fundamentally the same wherever they go.

Global retailers, particularly fast food retailers have been discussed as new forms of global imperialism. Global imperialism means that the retailers alter material culture wherever they go. Authors such as Ronald Steel and Thomas Friedman argue that McDonald's and other manifestations of global culture serve the interests of middle classes that are emerging in autocratic, undemocratic societies.

Global retailers' motivation for international expansion is to exploit a unique concept before others have a chance to do this. Global retailers therefore may expand to other countries without saturating their home market. Their quest is not a simple quest for growth but a need to colonize their concept.

Colonizing a concept means that one expands very rapidly before others can mimic one's idea. Although all global retailers expand internationally more rapidly than multinational retailers, there is a group of exceptionally fast internationalizers. These companies expand internationally nearly from their inception. In the marketing literature, Knight and Cavusgil (1996) term these companies *Born Global*. The *Born Global* literature focuses on learning in networks to explain the quick international expansion. The early movers in retailing do not depend on learning networks, but instead focus on colonizing the concept. Being first with the idea gives significant first-mover advantages. They are not changing their offering, so there is no real need to learn about the international environment.

Multinational. The second type, a multinational retailer, is decentralized and adapts its product offering to the culture it is serving. It is usually a large-scale format, which would be

difficult or impossible to develop into a business format franchise. If this type of retailer wishes to use a low-cost alternative for international expansion, they do not have the option of franchising and will have to use licensing instead. Wal-Mart's Supercenters, warehouse clubs such as PriceClub, and supermarkets such as Tesco are multinational retailers. These retailers adapt to the cultures they are entering. They generally source merchandise locally and try to hire and train management from the local area.

We can best understand multinational retailer's internationalization as a strategy for growth. These retailers do not generally internationalize before they have saturated their home market. This saturation may be because of natural market expansion or, as we more often find in Europe, government restriction on large-scale store expansion. This can explain why European food retailers have been the most aggressive in cross-border expansion.

Some of the first multinational retailers to expand internationally were the Japanese department stores and General Merchandise Stores (GMS). These companies moved into Hong Kong and Taiwan to avoid the competitive environment of Japan where large-scale store laws prevented their expansion at home. These early international moves were defensive. The first Japanese department stores to internationalize such as Yaohan were weak in their home market. In the end, most of the early Japanese department store retailers' international expansion failed. A second wave of Japanese department stores expanded to Hong Kong and Taiwan with the intention of learning how to do business in the Chinese business environments. Companies such as Isetan were successful in using Hong Kong and Taiwan to launch operations in China.

Most large-scale European retailers that internationalized were food retailers (Sternquist, 1997b). They did not generally enter foreign countries until they had saturated the home market. Growth needs fueled their international expansion. In this case, unlike the Japanese early expander, international expansion was part of their strategic growth.

Since multinational retailers have a large-scale format, they do not have a franchising option. Franchising requires that the business format

be such that it can be standardized, essentially codifying the knowledge, which can then be transferred to foreign outlets. Multinational retailers who want to use a low-risk alternative must use licensing rather than franchising. Licensing is a risky move for a company because they have little control over what the licensee will do with the name.

THEORETICAL EXPLANATIONS FOR INTERNATIONALIZATION

Stages theory focuses on the pattern of internationalization. According to stages theory, a company will initially expand to countries that are most similar to their home market. Then with experience they will expand to countries that are less similar. Dunning's (1981) eclectic theory focuses on ownership, location, and internalization factors. Institutional theory explains the influences of macroenvironment and microenvironment on a company's decision to internationalize. The final conceptual link is risk theory. Retailers evaluate foreign markets according to their perceived level of risk. Much of a retailer's in-country investment is for inventory and physical facilities, an investment that is not liquid, and therefore not salvageable in the short run if a government determines that they should not operate there anymore, or if they simply cannot survive.

The export stages literature views internationalization as a step-by-step process where higher level stages represent a higher level of international involvement than lower stages (Cavusgil, 1982, 1984). This paradigm relies on characteristics of management to delineate the stages they are ready to assume. However, the stages available for retailers are different from those available to manufacturers. Retailers do not have an export option. The stages for retailers are based more on risk and knowledge. Multinational retailers will begin their international expansion in countries that are culturally similar to the home country. They will develop this area or region and then make a jump to another geographic area which is not culturally similar, and develop area expertise through local expansion. As they gain experience in each country or region, they move into another area. Eroglu (1992) provides the basis for predicting which firms will seek international

expansion because of organizational characteristics such as size, experience, and international orientation. These organizational characteristics are directly related to the propensity for international expansion.

Retailers make mistakes in their internationalization efforts. A failure can be very valuable for a retailer's long-term success because failures are analyzed more than successes. Analysis leads to learning. Carrefour is a good example of a company that withdraws from markets in which it is not successful. As a result of this trial learning, the company has compiled a vast portfolio of information about how to do business in other countries. Carrefour's most recent move was to acquire GB, a Belgium firm. Belgium was the first country Carrefour entered (1969). They withdrew after their initial entry. However, after over thirty years of international experience they are ready to reenter through acquisition.

Researchers have developed most international business models from the manufacturing perspective. The two major international business research paradigms are the behavioral school and the export stages view. The behavioral school considers internationalization as an incremental process of strategic growth based on a firm's general and experiential market knowledge and resources. Increased market knowledge enables the firm to have higher international involvement. This view assumes that knowledge and experience accumulates in a firm's internationalization growth and allows the firm to control risks associated with internationalization. The behavioral internationalization paradigm has been used as a model for international retail involvement. Results confirm that strategic management characteristics, competitive advantage related to retail concept and logistics and retailer's size are related to retail internationalization (Vida, Reardon, and Fairhurst, 2000).

Both these models assume that international activities are at higher risk than domestic expansion, the internationalization process is sequential (lower involvement leading to higher involvement), and internal firm factors influence international involvement rather than macro-environmental factors.

Retailing differs from manufacturing internationalization. Retailers often do not use sophisticated decision models before internationalizing.

They are more likely to take an international move and then assess the impact of the move. Yip, Biscarri, and Monti (2000) observed this ad hoc approach when they studied the internationalization of small and medium-sized firms. Retailers also consider country economic characteristics more than manufacturers do, because they must have a physical presence in the country. Therefore, a theory to explain retailer's international expansion should include: (i) the exits, as well as the entry, into foreign markets and (ii) within-country competitive, economic, and development factors.

Dunning's eclectic theory Sternquist (1997b) focuses on ownership (O), location (L), and internalization (I) factors that influence a company's decision to internationalize. In addition, institutional theory helps explain how a retailer's macroenvironment—the host country and home country—and microenvironment—the retailer's past experience and competitors' move—affect the retailer's internationalization decision.

Eclectic theory.

Ownership advantages (O). Ownership advantages include innovative or unique products or processes the company can use to obtain market power. This grouping includes asset-based and transaction-based advantages. Asset-based advantages refer to tangible items such as patents or unique products. Global retailers generally have significant asset-based ownership advantages, since they often focus on private label merchandise. Private label can be considered as an important ownership advantage. However, private label does not necessarily translate well when a company internationalizes. Retailers such as Zara and Mango are defined by their private label concept. In this case, the private label is an asset in international expansion. Also, because private label is easily expanded to international settings it makes the asset transportable. In contrast, multinational retailers are generally mass merchandisers and for these retailers private labels do not transfer well in an international setting. A good example of this is Marks & Spencer, a UK company that focuses on general merchandise and food offerings. Although they had a very successful start at internationalization in selling

their products in Hong Kong (a former British colony) and other communities where there was a strong affiliation to the Marks & Spencer concept, this success diminished when they had less of an expatriate clientele. As a result they have had to back out of many markets where they thought they would be successful. Gielens and Dekimpe (2001) found in their study of European food retailers that private label was not related to sales and efficiency. The bottom line is that very targeted retailers such as Mango and Zara are looking for a distinct segment of consumers who like their product throughout the world, but large-scale retailers have a difficult time using their private label effectively because the mass population are not familiar with, and do not accept, private label merchandise from a retailer they do not know.

Transaction-based advantages come about because of the way things are done. Customer service or centralized buying are examples of transaction-based advantages. Transaction-based knowledge is highly tacit; transferring it to others is difficult and is characterized through learning by doing (tacit learning). Transaction-based ownership advantages are difficult to transfer to another country. This both protects this type of ownership advantage from being copied, but also makes it difficult to use franchising to transfer the knowledge.

Transaction-based advantages include knowledge about how to internationalize. Carrefour and Metro are two food retailers with long-standing experience in emerging markets. This has given them ownership advantages in three major areas. The first is in people. Carrefour's years of international experience have given them a pool of experienced managers. These managers can be used to open new stores throughout the world. Carrefour has decentralized stores, giving managers extensive decision-making experience. Recently, Carrefour has been moving toward greater centralization to gain economies of scale in purchasing. The second area advantage is the hypermarket/warehouse club concept. This concept is particularly well adapted to emerging markets, where consumer purchasing power is growing rapidly from low initial levels. Also, large store formats benefit from being in areas where land is reasonable,

available, and not heavily regulated by the government. The third area of ownership advantage is their negotiating position with suppliers. Carrefour's international expansion is a textbook example of how a multinational retailer internationalizes. Carrefour's early international success came about because of their "first mover" advantage. Their first internationalization efforts were in Northern European countries. These movements were not successful and the company retreated. Over time the company began to expand to less developed countries such as Spain, where they had a great deal of cultural similarity. They then expanded to South America, where they were able to capitalize on their knowledge of doing business in Latin cultures. As other multinational food retailers entered the markets and competition increased, they have begun to struggle (Evans and Mavondo, 2002). In 2005, Carrefour withdrew from Mexico, forced out by Wal-Mart's initiated price wars.

Interviews with retailers revealed that they internationalized because they had this "wall of cash" that they had to do something with. They had been successful and now they had to reinvest their earnings. Also, many retailers said that the investment community expected them to internationalize, and would look at their company unfavorably if they did not move outside their home borders. This means that stock market analysts would not suggest investing in their company if they did not expand. So, some international expansion is related to satisfying the investment community, a source of revenue for publicly held companies.

Locational advantages (L). Locational advantages relate to how suitable the host country is with respect to the firm's strategies. In other words, how well does the country provide a comfortable place for the retailer to reside? Pellegrini's (1994) work identifies issues relevant to retailing.

Cultural proximity: People in some countries share similar patterns of life. Midwesterners in the United States are more like Midwesterners in Canada than US residents on either coast. Europe has three bands of culturally similar groups divided

geographically by horizontal bands, rather than distinct country groupings. French hypermarkets dominate the Spanish market. German department stores have expanded rapidly into what had been East Germany. These are examples of retailers expanding into culturally similar environments. Cultural proximity is more important for multinational retailers, and becomes insignificant when retail concepts involve narrowly defined consumer markets, namely, global retailers.

Evans and Mavondo (2002) considered the relationship between psychic distance and organizational performance. Psychic distance is conceptually the opposite of cultural proximity. They found that psychic distance has a positive effect on organizational performance. Their explanation for this finding is that retailers who perceive a difference in culture between the home and the host country will make adaptations while those who perceive no distance will not make adaptations. This finding is an example of where the type of retailer is likely confounding the results. If these authors had separated retailers into global versus multinational they would likely find that psychic distance is not important to global retailers because they are selling to essentially the same customers throughout the world. Global retailers will enter world cities, selling essentially the same thing they sold at home. Multinational retailers will enter countries initially that have the smallest cultural distance to the home market, but over time they will expand to countries that are culturally distant.

Market size: There are both push and pull factors related to market size. Push factors mean that the retailer's growth in the home market is limited and they need to seek other environments. Saturation in the home country is an impetus for foreign direct investment by multinational retailers. Ample space for expansion must be available, particularly if the firm needs to reach a certain size to exploit economies of scale. Legal restrictions governing growth in the home country can be considered a motive for companies moving to foreign locations. France, Belgium, Germany, and Spain have stringent requirements that

limit large-scale retailers' growth, pushing retailers to expand outside national borders.

The French government passed a law in 1996 that set much more restrictive limits on new store openings. The law has essentially put an end to new hypermarket openings. Hard discount retailing, the small-scale version of warehouse clubs, will also be affected by the law. Hard discount stores are typically 900 m² in size. The new legislation lowers the minimum store size requiring authorization to 300 m². This limits further growth even for hard discounters.

Market pull factors are those that make a foreign market look attractive. Multinational retailers will seek countries that are less developed than their home market. Markets with high growth in income can provide retailers with double-digit growth. Global retailers are not affected by the level of economic development in the country. They seek world capitals where a homogeneous consumer resides.

Multinational retailers who enter less developed countries are also expected to alter their product offering so that food becomes a larger percent of sales. Consumers in less developed countries spend a higher percentage of their total disposable income on food. Wal-Mart sold very little food in its stores until they entered Mexico. In Mexico, their joint venture partner, Cifra was the country's major food retailer. Their joint venture businesses had a heavy focus on food. This joint venture has subsequently been terminated.

Competitors' moves: A first-mover advantage may be lost if competitors enter a foreign market. Competitors may secure prime retail locations and block out other firms. Within any major city, there are only a few prime retail sites. The larger the retailer considering international expansion, the more crucial it is to be an early mover. Like a strategic game of chess, the early moves of a large retailer sets the stage for a long-term competitive advantage. Competitor's moves have little impact on global retailers.

Geographic proximity: Expanding closer to home reduces costs related to transportation and corporate communication. Geographic

proximity is important for retailers selling private labels produced in a central location. Geographic proximity is less important for decentralized companies because they are allowed to operate as independent units, generally sourcing from within the country. Even before the peso devaluation, Wal-Mart Mexico purchased 80–90% of their products from Mexican sources.

Low-cost land and labor: Carrefour has a policy of owning their stores. When Carrefour opens in a new commercial zone, it attracts the best tenants to the hypermarket complex. This gives them a strong economic justification to own their own outlets, and the whole shopping center, if possible. Only in countries where the cost of commercial land is exorbitantly high, or where, for legal reasons, they cannot obtain title, does Carrefour agree to be a tenant. This was the case in Taiwan until 1996 when the government reduced restrictions on foreign ownership of land. Even in China, where land cannot actually be owned, but only obtained through a long-term lease, Wal-Mart builds its own stores.

Internalization (I): The greater a company's ownership assets, the more important it is to protect these assets by guarding company secrets. Internalization entails keeping the information within the company. In retail franchising, the company sells or leases ownership assets to other firms. Therefore, franchising is a particularly dangerous idea for retailers with strong transaction-based ownership advantages. Retailing innovations are difficult to defend from imitators. Competitors can freely copy them because there are no patents on retail know-how; therefore, to maintain a competitive advantage, the retail company needs to internalize its innovations. The only way for a retail company to keep its operating secrets is to open wholly owned subsidiaries in various countries. This is too expensive for many companies. They are forced to franchise their retail innovations to expand rapidly. However, over time they may regret this decision because they will have lost organic growth opportunities in that area. There is one instance where franchising is

actually a smart strategic move, that is, if you know that your retail format will be copied rapidly and you have to franchise to be able to move quickly enough.

A primary attraction for the use of franchising in overseas markets might be rapid expansion. For some companies, foreign markets may be viewed as providing favorable opportunities for growth, regardless of the level of development of the domestic market. Many retailers, for example, *Body Shop*, *Benetton*, *Marks & Spencer*, and *Mango*, have increasingly adopted franchising as an expansion method. This tendency is consistent with the premise that the global retailer with an innovative concept expands rapidly to fully exploit the ownership asset because expansion is rapidly accomplished through a franchising system. Many retail firms use other strategies to achieve rapid growth objectives. With a highly innovative retail and brand concept, and a primary growth method through wholly owned subsidiaries, *Zara* almost instantly expanded into 30 countries, adding nearly 250 stores from 2001 to 2003. Also, *GAP* with well-defined concepts has used direct investment, rather than franchising, and achieved rapid expansion (Park and Sternquist, 2008). Given the existence of global retailers using the wholly owned entry mode to expand rapidly, there may be some intervening factor that influences a global retailer's mode choice of entry with regard to rapid expansion.

There are two theoretical explanations for franchising, namely, agency theory and resource based theory. Agency theory suggests that companies franchise because monitoring of the foreign subsidiary is very difficult, and therefore making the foreign entity an owner manager will reduce the tendency to cheat. Resource-based theory suggests that firms franchise because they cannot afford to expand on their own. Although we cannot predict which theory explains a firm's decision to franchise when they begin the internationalization experience, over time we can have an idea of the correct explanation. If the company begins to reacquire their franchise outlets on amassing resources, then this would lend support to the resource-based theory. In other words, if they find themselves with money and they use this money to buy back franchisees

then we can conclude that it is resource-based theory that is in play.

Joint ventures are when two companies join together to create a new entity. For instance, when Wal-Mart went to Mexico, they entered into a joint venture with Cifra to open super-centers called Bogata. In a joint venture partners share information and knowledge, which means that joint ventures offer less protection of secrets than wholly owned subsidiaries. Sometimes joint ventures are needed when entering a different cultural environment or because of government regulations. Many developing countries require that domestic ownership have controlling interest of multinational companies. International retail joint ventures nearly always involve a multinational retailer. Generally, the foreign retail joint ventures involve a foreign company that needs to learn the culture and business practices in a new country. They select a joint venture partner in the country that will provide them with this type of information. However, once the foreign retailer learns how to do business in the foreign country they are likely to acquire the newly formed enterprise. Therefore, retail foreign joint ventures are posited to be temporary in duration. The concept that foreign joint ventures are only useful until the foreign company has learned the culture is interesting.

OTHER THEORETICAL EXPLANATIONS FOR INTERNATIONALIZATION

Institutional theory. Institutional theory emphasizes that a retailer's institutional environment influences its decisions and behaviors (Huang and Sternquist, 2007). Here, the institutional environment not only consists of regulatory structures, laws, rules, cultural beliefs, norms, and habits but also customers, suppliers, and retailers itself. Retailers' international expansion leads to the transfer of retail management technology across boundaries. External environment factors such as different cultural, legal, political, social, and economic factors affect retailers before they make decisions as to where, when, and how to expand into another country. Half of the top 50 companies in the S&P 500 were established within the past 20 years, yet they began to internationalize only within the past 10 years. These companies include retailers such

as Home Depot and Best Buy. As retailers increasingly consider international expansion as a viable growth option, entry location, entry timing, and *entry* mode remain as the cornerstones of retailers' market entry strategy. For retailers, franchising (or licensing), entering into a joint venture and setting up a wholly owned subsidiary are most distinct modes of entry into a foreign market. Different entry modes represent different levels of *resource commitment*, and control over the foreign operation.

Scott and Christensen, (1995) classified three kinds of institutional systems – *regulative*, *normative*, and *cognitive* systems representing legal, social, and psychological elements and the focus here is on the influences these three dimensions on retailers' decision making and behaviors of international expansion.

Regulative dimension. Institutional theory emphasizes legal and political factors specific to a country. The home and the host country's legal regulations represent the strongest environmental pressures faced by retailers. For example, the Large-scale Retail Store Law (LSRS) in Japan not only significantly impeded the expansion of foreign retailers such as Toys "R" Us (Scott and Christensen, 1995), but also pushed Japanese retailers such as Isetan to expand internationally.

A country with a strong rule of law is defined as one having sound political institutions, a strong court system, and provisions for orderly succession of power. A strong rule of law represents freedom of transacting, security of property rights, and transparency of government and legal process. The rule of law is a double-edged sword. On the one hand, rules establish a stable structure to reduce uncertainty about what protection retailers can expect from the host country's legal system. On the other hand, foreign operation restrictions can be the barriers to retail firms.

Countries with a weak governance infrastructure have to improve to be able to attract foreign investment. Researchers have found that the improved legal environment is a significant determinant of the timing of entry. Retailers are more likely to establish wholly owned subsidiaries in transitional economies that have progressed furthest in institutional reform. However, if the rule of law gets more

and more restrictive, such as Japanese's LSRS law, retailers may lose interest in expanding or prefer entering using franchising or licensing.

Normative dimension. The normative dimension of the institutional theory gives priority to norms and cultural influence. For a retailer who sells consumer goods overseas, the cultural difference between consumers from the home and the host country will probably be one of the most important factors to be taken into consideration when determining the form of market entry. Toys "R" Us expands with some adaptation to different markets. Though the overseas stores are formatted similarly to those in the United States, its merchandising selections are different. Twenty percent of its merchandising assortment is chosen for local consumer interests. For example, the Japanese market prefers porcelain dolls whereas Germans prefers wooden toys.

The cultural distance between the retailer's home country and the host country affects the choice of foreign expansion form. Many researchers support the theory that greater cultural distance results in low control entry modes such as franchising and licensing. In the case of high cultural distance, retailers may perceive high risk of entering a foreign market and feel high pressure of serving different customers. Accordingly, they may prefer not to enter the country or delay the entry. However, if the benefits to be reaped in the foreign market are high enough, retailers may still wish to enter into the country. In order to "fit" into the new environment, retailers may choose adaptation. Wal-Mart did not initially adapt its retail format in Argentina to the local culture. However, the retailer learned valuable lessons there that helped its subsequent operations in similar situations.

Adaptation is a long-term and accumulative process. Retailers may seek local partners to accelerate the process. On the contrary, retailers are more likely to enter countries with cultures that are similar to the home market before entering countries with less similar cultures. In this case, retailers may choose wholly owned subsidiary because a high level of understanding of norms and values has already been shared; therefore, local partners are less needed.

Cognitive dimension. The cognitive dimension of the institutional theory explains why a global retailer such as The Body Shop always uses the same entry mode during international expansion. From a cognitive perspective, organizations possess habits and inertia. As Porter (1990) notes: "Firms would rather not change . . . Past approaches become institutionalized in procedures and management controls . . ." Retailers tend to use entry modes consistently, especially when the situations are similar to the past. The primary form that the internal institutional environment can influence entry mode choice is through habit, which means that once a practice or decision has been chosen and implemented, the likelihood of alternatives being considered and used in future decisions will be reduced. Habits and inertia preclude rational changes.

Further, retailers can learn not only from their own experience but also from the experience of others, such as competitors. Strategic choice theories suggest that imitation can be a strategic response to competitor activities, whereby second-movers take advantage of the fact that the risk associated with new situation has been absorbed by the first-movers. In other words, copycats can be successful too. A retailer could decide which country to enter by following other retailers. For example, China has been one of the most popular investment destinations in the world. For several years in the 1990s, China was the second largest recipient of FDI worldwide. One motivation for foreign firms investing in China is to meet their competitors' move to China and/or forestall or reduce competition from other firms' earning markets in the same geographical area. When considering a totally unknown foreign area where minor similarities could be found in terms of previous practices, retailers will naturally avoid or try to postpone the consideration first. Nevertheless, if the retailer decides to expand into this new area and has no past experience to rely on, the retailer may resort to other retailers' experience, that is, to mimic others expansion behaviors.

Risk theory. The final theory is related to risk. Multinational retailers will begin their international expansion in countries that are culturally similar to the home country. As they gain experience in each country or region, they

move into another area. In Eroglu's (Cavusgil, 1984) conceptual model, she provides the basis for predicting which firms will seek international expansion because of organizational characteristics such as size, experience, and international orientation. These characteristics reduce risk or increase knowledge which is needed to handle risk.

Risk theory also relates to how much investment a company puts into international expansion. Global retailers who seek a less risky alternative can select to franchise. Multinational retailers who seek a less risky alternative will have to license. Franchising and licensing both require the relinquishing of company assets.

SUMMARY AND CONCLUSIONS

This article provides the conceptual overview for understanding international retailing. The study of international retailing and retail internationalization is very different from the study of international marketing and market internationalization. Retailing is geographically based. Laws regulating international trade do not affect international retailing, as the retailers can source in each domestic market. Instead, retailers need to be aware of intracountry business laws and regulations.

Retailers must assess their company's strengths and the relative attractiveness of continued domestic growth or international growth. They must determine whether it is important to keep company knowledge to themselves and use it for their continued international expansion.

Retailers use the macroenvironment – economic, competitive, technological, social, and governmental – and the microenvironment – competitors, past experience – to make decisions about their retail offering. This decision is twofold: first, should they enter the foreign market? And, if they decide to enter the market, should they use a standard retail format (global), or should they adapt their retail offering (multinational)? The issues are who should go, where to go, and how to go. Such issues are also related to the decision to rely on centrally versus decentrally managed operations.

The macroenvironment influences a country's locational advantage. A company's ownership

advantages will influence whether it will internalize its secrets. This decision will, in turn, influence whether the company uses a standard format or a format that is individualized for each country.

**designing a global supply chain:
opportunities and challenges**

David J. Closs

Globalization (*see* GLOBAL CONSUMERISM AND CONSUMPTION) offers many opportunities and challenges for logistics and supply chain operations and strategies. The opportunities include increasing markets and a wider range of manufacturing alternatives with varying absolute and comparative human and material resource advantages (*see* COMPETITIVE ADVANTAGE: ITS SOURCES AND THE SEARCH FOR VALUE). Some regions of the world can offer significant economies of scale because of their competitive wage scales, while other regions offer significant flexibility because of their expertise. The challenges encountered when taking advantage of these benefits include more demanding logistics operating environments, security considerations, and more complex total cost analyses (Bowersox, Closs and Cooper, 2010).

GLOBAL ECONOMIES

Regardless of size, most firms today include some dimension of global operations. They have materials or products that are sourced globally or global customers wanting to purchase from them (*see* GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES). In many cases, firms are involved in both global sourcing and delivery. Table 1 lists the primary rationale for firms to globalize. While many believe that the primary motivation for shifting manufacturing and supply chain operations is low-cost resources and labor, the rationale in many cases is one of the others cited in the table. For example, although it is believed that many firms moved production to Asia and India to access lower production wages, their primary motivation was often to obtain access to rapidly growing markets. While many have taken advantage of rapidly increasing demand, the increased demand for employees in production is driving up wage rates much more rapidly than in the developed world. As a result, the wage differential is declining and firms are beginning to look for the next low-cost production sources which today

include Vietnam and Cambodia. Firms are also beginning to develop supply chain value-added capabilities in South America and Africa to take advantage of market proximity to the developed world and low-cost production.

Global supply chain operations either directly or indirectly is becoming the norm for most firms. Global sourcing and marketing offers many opportunities to enhance the firm's performance particularly in terms of revenue, volume, and market share (*see* GLOBAL SOURCING STRATEGY: AN EVOLUTION; EMERGING MARKETS). The following section describes some of the strategies firms employ to achieve these benefits along with some of the challenges that firms are likely to encounter.

GLOBAL SUPPLY CHAIN INTEGRATION

Just as an effective logistics system is important for domestic supply chain integration, it is absolutely essential for successful global sourcing, manufacturing, and marketing. Domestic logistics focuses on performing movement and storage activities to support supply chain integration in a relatively controlled and consistent environment. Global logistics must support operations in a variety of different national, political, and economic settings while also dealing with increased uncertainty associated with the distance, demand, diversity, and documentation of international commerce (*see* FORCES AFFECTING GLOBAL INTEGRATION AND GLOBAL MARKETING).

The operating challenges of global logistics systems vary substantially in each major global region. The North American logistics challenge is one of an open geography with extensive and relatively integrated transportation options and limited need for cross-border documentation. The European logistician, in contrast, is confronted by relatively compact geography involving numerous political, cultural, regulatory, and language situations. The European infrastructure is also quite congested because of population density and the fact that many of the roads date back centuries. The Pacific Rim logistician faces an island-based environment with relatively poor infrastructure, requiring extensive water and air shipments to transcend vast distances. These different

Table 1 Rationale for globalization.

| <i>Objective</i> | <i>Rationale</i> |
|------------------------------------|---|
| Increase revenue | <ul style="list-style-type: none">• Open up more markets• Expand beyond competitors• Obtain accessibility to markets that limit access without local operations |
| Achieve economies of scale | <ul style="list-style-type: none">• Take advantage of available production capacity allowing sales of more volume |
| Reduce direct cost | <ul style="list-style-type: none">• Take advantage of lower labor rates or real estate expense• Reduce energy requirements by reducing distance or changing transportation mode• Take advantage of differences in production requirements |
| Advance technology | <ul style="list-style-type: none">• Obtain access to advanced technology that may not be available from current locations due to historical investments• Obtain access to specialized expertise or language skills |
| Reduce firm's global tax liability | <ul style="list-style-type: none">• Obtain local or regional tax benefits related to property, inventory, or income• Obtain reductions in value-added-taxes due to localized production or other value-added services (i.e., packaging, inventory management, customization) |
| Reduce market access uncertainty | <ul style="list-style-type: none">• Source product from location that involves less transportation uncertainty• Source product from location that involves fewer security constraints |
| Enhance sustainability | <ul style="list-style-type: none">• Source products or other resources (including human resources) from locations that have ongoing availability of materials and expertise such as energy or trained workers |

characteristics require that firms having global operations develop and maintain a wide variety of capabilities and expertise.

In the past, an enterprise could survive by operating with unique North American, European, or Pacific Rim business strategies. While it was easier to create and operate unique regional strategies, the resulting duplication often resulted in loss of economies of scale and poor asset utilization. While regionalization remains viable for some firms, those desiring to grow and prosper must face the challenges of designing and operating a globally integrated enterprise. Strategic business initiatives must change as a firm and its supply chain become progressively more global.

STAGES OF INTERNATIONAL DEVELOPMENT

The continuum of global trade development ranges from the lack of an international strategy to the concept of a globally integrated enterprise. The following discussion describes conceptual and managerial implications of strategic development (*see* STAGES OF MARKET DEVELOPMENT). Table 2 lists the product, marketing, supply chain, management, information technology, and human resource strategies characteristic for each stage of globalization.

Differential characteristics of global development.

No international strategy. The initial stage of many firms' global trade is characterized by the lack of an international strategy with

occasional exporting and importing. Such organizations typically focus on their domestic operations and perceive international transactions as a requirement to support domestic business. Specifically, a firm uses a simple export/import strategy to increase the revenues or decrease costs associated with a domestic operation. As Table 2 indicates, lack of an integrated international strategy typically involves a standardized product manufactured in the firm’s home country, focused on a limited customer base, with logistics services required for export/import provided by specialized integrated service providers (ISPs). The business context is transaction driven, with common financial statements providing the only level of integration.

Multidomestic strategy. The second international development stage essentially takes the domestic model and replicates it in various locations around the world. As Table 2 indicates, the marketing, operations, and financial strategies mimic the firm’s domestic operations while the management and human resource perspectives have a strong home country bias.

While this approach does not require much

coordination, it also does not take advantage of potential synergies and economies of scale. This is increasingly a problem when many of the firm’s key customers are global and expect a common global offering. From a logistics perspective, the multidomestic strategy does not share the logistics expertise and relationships across regions.

Global strategy. The third stage of international development is characterized by establishment of integrated marketing and supply chain operations in foreign countries. Global operations may include varied combinations of marketing, sales, production, and logistics. Establishment of local facilities and operations serves to increase market awareness and sensitivity. This is often referred to as establishing *local presence*. The local presence strategy uses local production and distribution often supported by a postponement strategy to customize products. Firms engaged in local presence often restrict their operations to a limited number of geographic areas. At the outset of a local presence strategy, foreign operations will often depend on parent company management and personnel, values, procedures, and operations. However, over time, business

Table 2 Differential characteristics of global development.

| <i>Development Stages</i> | <i>Service Focus</i> | <i>Marketing Strategy</i> | <i>Delivery Strategy</i> | <i>Management Strategy</i> | <i>Human Resource Development</i> |
|---------------------------|---|--|----------------------------------|---|--|
| No international strategy | Standard product for local market | Single strategy focused on local market | Direct to customer | Single simple financials | Operated by entrepreneur with limited specialization |
| Multidomestic strategy | Domestic marketing and delivery | Domestic customers | Collaboration | Transaction driven with integrated financials | Management with “home country” focus |
| Global strategy | Local market customization | Focused specific market areas which may cross international boundaries | Subsidiaries with local presence | Decentralized operations with local profit responsibility | Limited top management with international experience |
| Transnational strategy | Global branding and integrated operations | Global customers | Worldwide flow of key resources | Centralized planning in global sites | International training and experience |

4 designing a global supply chain: opportunities and challenges

units operating within a foreign market area will have to adopt local business practices.

This adoption typically means developing unique management, marketing, and sales organizations and may include the use of local business systems. As local presence operations expand, the host country philosophy will increasingly emerge; however, the company headquarters' strategic vision remains dominant. Individual country operations are still measured against home country expectations and standards.

Transnational strategy. The transnational strategy contrasts sharply with operations guided by either a multidomestic or global strategy. The original concept of the globally integrated enterprise was popularized in a *Business Week* article two decades ago under the term "The Stateless Corporation" (The Stateless Corporation, 1990). Management of a truly globally integrated enterprise makes market, location, and resource decisions with little or no regard to national boundaries.

Globally integrated enterprises maintain operations and develop a headquarters structure to coordinate across area operations. "Unlike the multinational – which creates mini versions of itself in markets around the world – the globally integrated enterprise locates work, skills, and operations wherever it makes sense, based on access to expertise, on superior economies, and on the presence of open environments and technologies." Thus, the enterprise is globally integrated in the sense that no specific home or parent country dominates policy. IBM offers a good example of an organization that is striving for global integration (Palmisano, 2008). Senior management likely represents a combination of nationalities. Denationalized operations function on the basis of local marketing and sales initiatives and are typically supported by world-class manufacturing and logistics operations. Product sourcing and marketing decisions can be made across a wide range of geographical alternatives. Systems and procedures are designed to meet individual country requirements and are aggregated as necessary to share knowledge and for financial reporting. A truly transnational firm employs global brands with limited customization to

reflect market sensitivities, operates in most global regions, employs a global resource view in terms of production and logistics, and incorporates integrated reporting systems and planning technologies to achieve global operating synergies. Although limited customization is desirable to minimize product complexity, the globally integrated enterprise can discriminate between features that represent a critical market difference and those that do not.

Consider, for example, an enterprise that has its historical origin in Germany, Japan, or the United States, but with a high percentage of its sales, ownership, and assets maintained and managed in China. China is estimated to be the world's third largest economy, but there are many supply chain aspects, such as logistics capabilities and infrastructure that are still quite third-world. China's communications, intermodal transport systems, tracking and tracing, and limited highways outside major cities make it very difficult to employ twenty-first century supply chain operating practices. For these reasons, a globally integrated enterprise operating in China needs a combination of local management to facilitate local operations and enterprise management that fully understands the implications of developing business systems, a rapid rate of change, and exploding but unbalanced export/import volume.

Examples of firms that fit the specification of globally integrated enterprises are ABB (Switzerland), Coca-Cola (United States), Dow Chemical (United States), Hoechst (Germany), IBM (United States), ICI (Britain), Johnson & Johnson (United States), Nestlé (Switzerland), Novartis (Switzerland), and Philips (Netherlands). These firms are characterized by a combination of global brands produced and marketed globally with integrated systems and management that can synthesize global operations while being sensitive to regional and local considerations.

While most enterprises engaged in international business are operating in stages one and two, to become a global player a truly international firm must migrate toward global marketing and operations. Such globalization requires a significant level of management trust that transcends countries and cultures. Such trust can

grow only as managers increasingly live and work across cultures.

Managing the global supply chain. To enhance a firm's global capabilities, logistics management must consider five major differences between domestic and international operations: (i) performance cycle structure, (ii) transportation, (iii) operational considerations, (iv) information systems integration, and (v) alliances. These considerations must then be incorporated into the firm's global operating strategy.

Performance cycle structure. The length of the performance cycle is a major difference between domestic and global operations. Instead of 1- to 5-day transit times and 2- to 10-day total performance cycles, global operational cycles often require weeks or months. For example, it is common for automotive parts from Pacific Rim suppliers to take 60 days from order release until physical delivery at a US manufacturing facility. Similarly, fashion merchandise may take anywhere from 30 to 60 days from the time the manufacturer order is released until it is received at a US distribution warehouse.

The reasons leading to a longer order cycle to delivery cycle are communication delays, financing requirements, special packaging requirements, ocean freight scheduling, slow transit times, and customs clearance. Communication may be delayed by time zone and language differences. Financing delays are caused by the requirements for letters of credit and currency translations. Special packaging may be required to protect products from intransit damage due to high humidity, temperature, and weather conditions. Once a product is containerized, it must be scheduled for movement to and between ports having appropriate handling capabilities. This scheduling process can require up to 30 days if the origin and destination ports are not located on high-volume traffic lanes or the ships moving to the desired port lack the necessary equipment. Transit time, once the ship is en route, ranges from 10 to 21 days. Port delays are common as ships wait for others to clear harbor facilities. Customs clearance may further extend the total time. Although it is increasingly common to utilize electronic messaging to preclear shipments

through customs prior to arrival at international ports, the elapsed performance cycle time is still lengthy (see DIGITAL MEDIUM AND GLOBAL MARKETING). Another problem is restricted availability of containers. Movement from Asia to the United States is generally unbalanced as more material is imported into the United States than is exported to Asia. As a result, there is a strong demand for containers to move product from Asia to the United States but little motivation to ship the empty containers back. This demonstrates how unbalanced trade, either domestically or internationally, can introduce complexity into logistics operations.

These factors cause international logistics performance cycles to be longer, less consistent, and less flexible than in typical domestic operations. This lack of consistency makes planning and coordination more difficult. Determination of shipment status and anticipation of arrival times also requires substantially more effort. The longer performance cycle also results in higher asset commitment because significant inventory is in transit at any point in time.

Transportation. The US initiative to deregulate transportation during the early 1980s has extended globally. The four significant global changes that have occurred are (i) intermodal ownership and operation, (ii) privatization, (iii) cabotage and bilateral agreements, and (iv) infrastructure constraints.

Historically, there have been regulatory restrictions regarding international transportation ownership and operating rights. Transport carriers were limited to operating within a single transportation mode with few, if any, joint pricing and operating agreements. Traditionally, steamship lines could not own or manage integrated land-based operations such as motor or rail carriers. Without joint ownership, operations, and pricing agreements, the operation and tracking of international shipping was very complex. International shipments typically required multiple carriers to perform a single freight movement. Specifically, government rather than market forces determined the extent of services foreign-owned carriers could perform. Although some ownership and operating restrictions remain, marketing and alliance arrangements among countries have

6 designing a global supply chain: opportunities and challenges

substantially improved transportation flexibility. The removal of multimodal ownership restrictions in the United States and in most other industrialized nations served to facilitate integrated movement. In response to some of these changes in national ownership requirements, an increasing number of global service providers have been established such as DeutschePost, FedEx, TNT, and United Parcel Service.

A second transportation influence on global operations is increased carrier privatization. Historically, many international carriers were owned and operated by national governments in an effort to promote trade and provide national security. Government-owned carriers are typically subsidized and often place surcharges on foreign enterprises that use these services. Artificially high pricing and poor service often made it costly and unreliable to ship via such government-owned carriers. Inefficiencies and inflexibility also resulted from strong unionization and work rules. The combination of high operating cost and low efficiency caused many government-owned carriers to operate at a loss. A great many such carriers have been privatized and must operate in a competitive environment. Carrier privatization has resulted in increased availability of efficient international carriers.

Changes in cabotage and bilateral service agreements are the third transportation influence impacting international trade. Cabotage laws require passengers or goods moving between two domestic ports to utilize only domestic carriers. For example, water shipment from Los Angeles to New York was required to use a US carrier. Similar cabotage laws restricted Canadian drivers from transporting a back haul load to Detroit once a shipment originating in Canada was unloaded in Texas. Cabotage laws were designed to protect domestic transportation industries even though they also served to reduce overall transportation equipment utilization and related efficiency. The European Community has relaxed cabotage restrictions to increase trade efficiency. Such reduced cabotage restrictions will save US corporations 10–15% in intra-European shipping costs. While the US has not rescinded its cabotage laws relating to Canada and Mexico, some of the restrictions have

been reduced to enhance equipment utilization and to reduce the environmental impact.

Many regions, both developed and undeveloped, are experiencing major constraints on their physical infrastructure. Global operations are significantly increasing the demand specifically on port and airport capacities. Since much of the infrastructure in the developed world was developed over 50 years ago, it was designed for substantially less capacity and without extensive growth capability in terms of surrounding land. Although information and handling technology has facilitated rapid movement of goods through ports and airports, the volume increase still results in substantial congestion (Norek and Isbel, 2005). At the same time, tight local, state, and federal budgets have limited the reinvestment that is made in the existing infrastructure. As a result, logistics managers are being driven to seek out alternative suppliers, carriers, or port locations.

Operational considerations. There are a number of unique operational considerations to support global supply chains. First, international operations typically require multiple languages for both product and documentation. A technical product such as a computer or a calculator must have local features such as keyboard characters and language on both the product and related manuals. From a logistics perspective, language differences dramatically increase complexity since a product is limited to a specific country once it is language-customized. For example, even though Western Europe is much smaller than the United States in a geographic sense, it requires relatively more inventory to support marketing efforts since separate inventories may be required to accommodate various languages. Although product proliferation due to language requirement has been reduced through multilingual packaging and postponement strategies, such practices are not always acceptable. Some consumers are reluctant to accept products not labeled in their native tongue. In addition to product language implications, international operations may require multilingual documentation for each country through which the shipment passes. Although English is the general language of commerce, some countries require that transportation and customs documentation

Table 3 Common forms of international logistics documentaion.

| |
|--|
| <ul style="list-style-type: none">• <i>Export irrevocable commercial letter of credit</i>. A contract between an importer and a bank that transfers liability or paying the exporter from the importer to the (supposedly more creditworthy) importer's bank.• <i>Bank draft (or bill of exchange)</i>. A means of payment for an import/export transaction. Two types exist: transaction payable on sight with proper documents (<i>sight draft</i>) and transaction payable at some fixed time after acceptance of proper documents (<i>time draft</i>). Either type of draft accompanied by instructions and other documents (<i>but no letter of credit</i>) is a documentary draft.• <i>Bill of lading</i>. Issued by the shipping company or its agent as evidence of a contract for shipping the merchandise and as a claim to ownership of the goods.• <i>Combined transport document</i>. May replace the bill of lading if goods are shipped by air (<i>airway bill</i>) or by more than one mode of transportation.• <i>Commercial invoice</i>. A document written by the exporter to precisely describe the goods and the terms of sale (similar to a shipping invoice used in domestic shipments).• <i>Insurance certificate</i>. Explains what type of coverage is utilized (fire, theft, water), the name of the insurer, and the exporter whose property is being insured.• <i>Certificate of origin</i>. Denotes the country in which the goods were produced to assess tariffs and other government-imposed restrictions on trade. |
|--|

be provided in the local language. This increases the time and effort for international operations, since complex documents must be translated prior to shipment. These communication and documentation difficulties can be somewhat overcome through standardized electronic transactions.

The second global operational consideration is unique national accommodations such as performance features, technical characteristics, environmental considerations, and safety requirements. Performance feature differences include specific product functionality such as speed or process constraints. Technical characteristics include power supplies, documentation, and metrics. Environmental considerations include chemicals that can be used or the types and amount of waste generated. Safety requirements include automatic shutoffs and specialized documentation. While they may not be substantial, the small differences between country requirements may significantly increase required stock keeping units (SKUs) and subsequent inventory levels.

The third operating consideration is the sheer amount of documentation required for international operations. While domestic

operations can generally be completed by using only an invoice and bill of lading, international operations require substantial documentation regarding order contents, transportation, financing, and government control. Table 3 lists and describes common forms of international documentation.

The fourth operating consideration is the high incidence of countertrade and duty drawback found in some international situations. While most established firms prefer cash transactions, countertrade is important. Countertrade, in essence, is when a seller agrees to accept products as payment or purchase products from the buyer as part of a sales agreement. While such agreements have financial consequences, they also have major implications for logistics and marketing in terms of disposal of goods received as payment. Duty drawback describes situations when a firm pays a duty to import goods into a foreign country but the duty paid can be drawn back or returned if the items or a comparable designate is exported. For example, Pepsi supplies syrup to the Soviet government, which bottles and markets the soft drink with practically no control from Pepsi. In return, Pepsi is paid for the syrup by receiving exclusive rights to distribute Russian Stolichnaya vodka in

8 designing a global supply chain: opportunities and challenges

the United States. This exclusive right requires marketing and logistics support.

Information systems integration. A major challenge in globalization is information systems integration. Since firms typically globalize by acquisition and merger, the integration of systems typically lags. Operational integration requires the ability to route orders and manage inventory requirements electronically throughout the world. Development of supportive technology integration represents substantial capital investment. The overall process was significantly facilitated by the global initiative to achieve Y2K compliance. Two types of system integration are required to support global operations. The first is a global transaction or enterprise resource planning (ERP) system. The global ERP system is necessary to provide common data regarding global customers, suppliers, products, and financials. It is also necessary to provide common and consistent information regarding order and inventory status regardless of the location from which a global customer is inquiring or where the shipment is to be delivered. The second system integration requirement is a global planning system that can maximize overall manufacturing and delivery asset utilization while meeting customer service requirements. Few firms have fully integrated global information systems or capability.

Alliances. A final international operations consideration is the growing importance of third-party alliances. While alliances with carriers and specialized service suppliers are important in domestic operations, they are essential for international commerce. Without alliances, it would be necessary for an enterprise operating internationally to maintain contacts with retailers, wholesalers, manufacturers, suppliers, and service providers throughout the world. International alliances provide market access and expertise and reduce the inherent risk of global operations. The number of alternatives, breadth of activities, and complexity of globalization require alliances.

In summary, globalization is an evolving frontier that increasingly demands more extensive supply chain integration. As firms expand their

focus toward international markets, demand for logistical competency increases because of longer supply chains, more variation, increased uncertainty, and more documentation. While the forces of change push toward borderless operations, supply chain logistics management still confronts market, financial, and channel barriers. The barriers are exemplified by distance, demand, diversity, and documentation. The challenge is to position an enterprise to take advantage of the benefits of global marketing and manufacturing by developing world-spanning logistical competency (Cudahy, Narendra and Cases, 2008).

SUMMARY

Global operations is becoming more of the norm for logistics and supply chain executives. Decisions regarding global sourcing and marketing require more complex trade-off analyses than traditionally required for domestic logistics. Both the quantitative and qualitative factors are more complex. While transportation, inventory, and warehousing costs are very substantial for global operations, other cost components, including taxes, tariffs, duties, documentation, and import restrictions, can also have a substantial impact on true total cost. However, in addition to the quantitative considerations, international operations introduce a number of other variables that are much more difficult to quantify. Many of these variables relate directly to logistics operations. The major qualitative considerations include relationship management, infrastructure consistency, production and transit reliability, and security. With increased global marketing and manufacturing operations, logistics management needs to be more involved in developing and implementing global strategies.

international advertising – is there still a standardization versus local adaptation debate?

Charles R. Taylor

INTRODUCTION

For nearly 50 years, a fundamental issue in the field of international advertising has been the degree to which advertising can be standardized. Even in recent years, standardization versus local adaptation of advertising is often positioned as a debate. A close look at the literature, however, reveals that the idea of a debate in which there is a “standardization camp” and a “local-adaptation camp” is quite dated (Taylor, 2005).

The weight of the research evidence suggests that, at least for large multinational firms, the use of GLOBAL MARKETING STRATEGY, including the creation of a global brand image, has major advantages and can lead to improved performance (Zou and Cavusgil, 2002). One need only to look briefly at the list of the world’s best global brands and their value to realize the dramatic advantage a global brand can provide (Interbrand, 2008). For example, in 2008, the top five brands were Coca Cola, IBM, Microsoft, General Electric, and Nokia. The top four of these brands were all valued at over \$50 billion. The symbols for these and many other famous global brands are so well entrenched with the average consumer, that they can be flashed on a screen for a period too short to actually read the company name or acronym, yet they are recognized and comprehended by consumers.

In the context of advertising, it has also been shown that given a reasonable level of market similarity the use of a standardized advertising strategy is positively linked to a firm’s strategic performance as well as its financial performance. The research suggesting that advertising strategy should be standardized does not in any way minimize the fact that cultural differences still matter. However, it does suggest that multinational advertisers should start the planning process by attempting to set similar broad strategies, including positioning statement and key selling proposition. Clearly, some aspects of execution will likely have to be adapted

in many cases, such as the language of the message, specific format of the commercial, actors, celebrities, or spokespeople used (*see* MARKETING CHANNEL STRATEGY).

A good analogy for planning global advertising strategy is to think of the process of manufacturing an automobile. The chassis of a given model can be the same for virtually all consumers. Meanwhile, a few different types of engines may be necessary to please consumers with different desires (performance vs. fuel economy), and numerous options are offered to tailor the product to the consumer’s individual preferences. Global advertising can be thought of the same way, in that every attempt should be made to standardize broad aspects of strategy such as positioning of the product (*see* POSITIONING ANALYSIS AND STRATEGIES), while some advertising tasks such as choosing broad media strategy may involve the need for a few modifications, and still others, such as the language of the commercial may need to be modified in many places.

In recent years, scholarly research has shown striking evidence that global advertising strategy pays off. The core reason for this is that frequently cited advantages of standardization pay off.

In examining international advertising from an academic perspective, it is now necessary to take into account both global perspectives on marketing theory at a strategic level as frameworks for understanding the role of culture at a more tactical level. In the following, frequently cited advantages of standardizing advertising versus adapting advertising to local markets are discussed (Czinkota and Ronkainen, 2008).

ADVANTAGES OF STANDARDIZED ADVERTISING

Levitt’s (1983) controversial article on the globalization of markets and discussion of the need to standardize the MARKETING MIX as a whole provided important perspectives on some key advantages of standardization. One of the advantages alluded to by Levitt is the achievement of economies of scale. In the context of advertising, this applies most directly to the need to develop and implement advertising campaigns more efficiently. Clearly,

2 standardization of international advertising

for a company operating in, say, 200 markets, developing a completely unique advertising campaign for each of the markets would be inefficient and cost prohibitive. Thus, developing a general strategy and, perhaps, even some tactical aspects of a global advertising campaign centrally can lead to cost savings. Additionally, at least in some contexts, there may be cost savings associated with making media buys that cut across borders, such as by advertising on EuroSport or Sky Channel (*see* MARKETING CHANNEL STRATEGY).

It has become increasingly clear that the establishment of a uniform global brand image is an additional advantage of standardization. Thus, a second key advantage of standardized advertising is that it can be used to help build a uniform brand image around the world. In this way, consumers recognize brands like Starbucks, Samsung, Toyota, Gucci, or Siemens regardless of where they are in the world. With increased evidence that it is possible to target cross-national market segments, it becomes even more important to build a common image while building brand equity cross-nationally (Ko *et al.*, 2007).

It can be argued that a third key benefit of standardized advertising is that it is appropriate for the modern world – described as a global village by Levitt in his discussion. As noted by Levitt, improvements in transportation and communications have led the trend toward consumers having more similar wants and needs than in the past. While Levitt may have exaggerated the degree to which convergence is occurring, there is little doubt that more consumers than ever desire similar types of high-quality goods and services. In such an environment, standardized advertising can capitalize on situations in which wants and needs are similar cross-nationally.

One final benefit of standardization that has been cited is the ability to better coordinate strategy. In the context of advertising, this refers to advertising strategy and campaigns being centrally planned so that they do not end up being in conflict and providing a conflicting image (*see* GLOBAL MARKETING STRATEGY). Simply stated, it is easier to plan and implement a strategy centrally as opposed to doing so in many different countries. At least, in the latter

case, more coordination is needed and more oversight is necessary.

ADVANTAGES OF LOCAL ADAPTATION OF ADVERTISING

Clearly, some aspects of consumer behavior and consumer wants and needs remain influenced by culture. While one can find Dunkin' Donuts locations in many parts of the world at a time when more European and US citizens are eating sushi and/or curry than ever before, it is, nevertheless, clear that cultural preferences and tastes play a role in many contexts. Thus, the ability to adjust to specific cultural preferences is important. In an advertising context, this may often involve a need to adapt the tone, format, length, or appeal type used in an advertisement. For example, it is well documented that “hard-sell” advertisements are not as well received in Japan as in some other parts of the world. While it is often possible to retain a single positioning statement to build the brand or general strategic elements of the message (e.g., which feature is being emphasized), quite frequently, there will be elements of the execution that must be altered.

A related advantage of adaptation is the ability to be understood in a local cultural context. This means both communicating in the appropriate language and also in terms understood by citizens of a country or region. Clearly, stubbornly running foreign language advertisements will simply result in failure in many advertising contexts. Perhaps less obvious, however, is the need to choose spokespersons or endorsers the audience in a country can directly relate to. This is easy to understand in the context of the use of celebrity endorsers. Most US citizens exposed to a reel of advertisements in which Korean celebrity endorsers are used to appeal to Koreans would not even be aware that celebrities were appearing in the advertisement.

A third important advantage of adaptation is that it is sometimes necessary to comply with legal restrictions or self-regulatory guidelines in a country. For example, Taylor and Raymond (2000) found that even among countries in the same region (East Asia), regulatory guidelines can vary a great deal, especially for certain types of products. For example, in Japan it is permissible to advertise the alcohol content

of a product and even refer to it as “*extra strong*,” a term that would not be allowed in many other countries. Alcoholic spirits may be advertised in some countries but not others. Similarly, DTC prescription drug advertising is banned in all OECD countries except the US and New Zealand, but other forms of promotion are allowed in various markets. When regulations vary across countries, advertisers may be obliged to adapt their strategy.

KEY EMPIRICAL STUDIES OF STANDARDIZATION VERSUS ADAPTATION

While a large volume of studies have been conducted on standardization and related issues, the findings of these studies have tended to converge. In a comprehensive review of the literature, Taylor and Johnson (2002) conclude that many companies have adopted an approach where broad strategies are standardized, but advertising executions are localized as needed. In a key study in the area using survey methodology, Harris (1994) found that most multinational companies use advertising, but the extent to which they use it varies. He emphasizes that the practitioners should focus more on “how” to standardize as opposed to “whether” to standardize.

Subsequent studies appear to verify Harris’ findings. In a major survey of multinational advertisers, Duncan and Ramaprasad (1995) found that strategy was most often standardized by multinational advertisers, while it was used less often in execution and least often in language. Notably, the authors found that the desire to achieve a uniform brand image was the number-one motivator for standardization – higher than the motivation provided by potential cost savings.

In an examination of whether advertising standardization by multinational corporations pays off in the form of improved financial and strategic performance, Okazaki, Taylor, and Zou (2006) conducted a survey of Japanese and US multinational firms operating subsidiaries in the European Union. Results showed a positive link between standardization and both financial and strategic performance. Again, however, the study provided evidence that strategic elements

are more likely to be standardized than executional elements.

While there has been some convergence in the research evidence as to how standardization is and should be used by multinational corporations, the findings suggest that theories pertaining to both global marketing as well as conceptual frameworks help understand and measure culture. If standardization is typically important at a strategic level, it is important to apply theoretical or conceptual perspectives that allow us to better understand how and why standardization strategies work. However, it is also clear that understanding and implementing standardization alone does not allow for fully effective global advertising. As a result, cultural and country-specific factors must be taken into account.

Fortunately, some recent advances in theoretical perspectives have allowed for better application to the issue of degree and effectiveness of standardized advertising.

GLOBAL MARKETING THEORIES

At least three major perspectives have begun to emerge that are aimed at better understanding the global market and how GLOBAL MARKETING STRATEGY work. A first theory is the global marketing strategy theory put forward by Zou and Cavusgil (2002). Drawn from industrial organization theory as well as additional perspectives, this theory proposes a model that outlines eight aspects of a global marketing strategy. The eight dimensions are product standardization, promotion standardization, distribution standardization, pricing standardization, coordination of value-adding activities (integration of competitive moves), global market participation, coordination of marketing activities, and concentration of marketing activities. Global marketing strategy theory argues that the degree of fit, referring to the degree to which a company’s own global marketing strategy matches up with the environment the firm faces, as well as its strategic capabilities, will have a profound impact on success.

Global marketing strategy can be applied to the context of advertising because it is a key element of promotion in many instances, and

4 standardization of international advertising

because it also reinforces product/branding strategy. Moreover, it clearly must be coordinated with other marketing-mix activities. Notably, in their study, Zou and Cavusgil (2002) found a positive relationship between following a global marketing strategy and financial and strategic performance under circumstances where the fit was sufficient.

A second influential theoretical perspective in the global marketing realm is global consumer culture theory (Arnould and Thompson, 2005). This theory argues that a trend toward a global consumer culture has indeed taken place and that market segments that cut across national boundaries can often be identified. In such instances, it should be possible for the multinational firm to improve performance. However, it is also notable that the global consumer culture theory avoids simply positing that consumers behave similarly around the world. On the contrary, the theory argues that similarities and differences can exist both within a culture and across cultures. This theory has also been applied to international advertising, and can be used to help explain some of the nuances associated with designing effective international advertising.

A third relevant perspective is an outgrowth of global consumer culture theory and can be referred to as the *global brand-positioning theory*. This work is an outgrowth of global consumer culture theory and was begun by Alden, Steenkamp, and Batra (1999). The basic idea is that the growth of global consumer culture has led to the development of a transnational consumer culture. In this environment, multinational firms realize an enhanced ability to target across countries the segments and consumers who have shared consumption values (Terpstra and David, 1991). A key finding from this line of research is that perceived brand globality is positively related to consumers' perceptions of the quality and prestige of the brand (*see* BRAND VALUE). Moreover, firms operating successfully in more regions benefit from higher global reach, which further contributes to a competitive advantage. In sum, this theory suggests that companies can achieve success by developing uniform positioning across markets and by achieving synergy as a result of operating across multiple markets (*see* POSITIONING ANALYSIS AND STRATEGIES).

In the context of advertising, global brand-positioning theory argues for the need to advertize a brand in multiple markets in a way that reinforces a single image. In this way, the benefits of higher perceptions of quality and prestige can be realized by raising perceived brand globality.

CULTURAL DIMENSIONS

The above theories have contributed to our understanding of how global strategies can be used successfully in advertising. Yet, as mentioned, there is a clear need to at least take cultural and country-specific measures into account in planning advertising executions. At least three major perspectives have had influence in the academic literature and they also have practical applicability.

The first perspective is that of the anthropologist Edward T. Hall, who contributed the idea of high-context versus low-context cultures to the literature. The difference in communication styles captured by Hall has been examined as it applied to advertising in several studies, many of which have shown that low-context cultures (e.g., the United States) tend to use more direct styles of communication in advertising, whereas less direct styles are often preferred in high-context cultures (e.g., Japan). Hall's classification of societies in terms of time orientation, in which some cultures have a monochronic time orientation while other have a polychronic orientation, has also been influential, though it has been applied less frequently to advertising.

A second and highly influential perspective on culture that has been widely applied to advertising research is Geert Hofstede's dimensions of culture (Hofstede, 1980). Indeed, Hofstede's original four dimensions of culture: individualism/collectivism, uncertainty avoidance, power distance, and masculinity/femininity have been widely studied in terms of their influence on differences in advertising. While some general criticisms of the Hofstede dimensions and the method by which they were derived have been made, there is no question that this perspective has contributed some insight into the subtle differences in advertising in different countries. For example, several studies have shown that there are differences in the types of

advertising appeals that work in individualistic versus collectivistic cultures. Power distance has been used to examine the depiction of rank and formality in advertising in various cultures. Studies have also applied uncertainty avoidance in terms of attitudes toward advertising of certain types of products (e.g., pharmaceuticals and over-the-counter drugs) and appeals. While masculinity/femininity has been applied less frequently, it has been included as a dimension in several content-analysis studies. Hofstede's long-term/short-term dimension, which was added later, has also been tested in some studies.

Recently, House and his colleagues (2004) have developed a competing set of cultural dimensions that has begun to be applied to advertising research. On the basis of a large-scale study of 62 countries, House identified nine cultural dimensions: performance orientation, in-group collectivism, institutional collectivism, power distance, uncertainty avoidance, future orientation, humane orientation, assertiveness, and gender egalitarianism. While this scheme and its methodology are also not without detractors, it is also beginning to be applied to advertising studies. From an advertising perspective, there is significant overlap with Hofstede's dimensions. However, dimensions of assertiveness and performance orientation have been of particular interest to researchers. It appears that the future will see more applications of this framework.

The three perspectives listed above are by no means the only cultural frameworks that have been applied to advertising. Several others, notable among them being the one suggested by Harry Triandis, have contributed important perspectives that advertising researchers have picked up on. As culture is a highly complex construct, it seems likely that work in studying and better understanding cultural dimensions and their impact on advertising will continue for many years. There have been many calls for a more general theory of culture as it applies to culture, but to date such a theory has been quite elusive, perhaps confirming to just how complex culture really is.

SUMMARY AND CONCLUSION

While standardization versus local adaptation is no longer categorized as topic of debate, there

is some merit in both perspectives. Research has demonstrated that global strategies can have advantages and, in most instances, marketers and advertisers are well advised to pursue global branding strategies reinforced by global advertising. At the same time, as one moves from strategies to executions, cultural differences and other country-specific issues do indeed matter, so localization issues must be considered. The weight of the evidence argues for considering global strategies first, realizing that, at the same time, executional modifications will often need to be made.

Future research will contribute more theoretical insight into global advertising. It is likely that this will occur both at a strategic level, with a focus on global strategies, and a more tactical level with a focus on cultural differences.

global marketing strategy: perspectives and approaches

Susan P. Douglas and C. Samuel Craig

INTRODUCTION

Markets worldwide are becoming increasingly integrated across national borders at a macroeconomic, competitive, and product market level. Firms of all sizes, and in almost all industries, are increasingly conceptualizing their strategy on a global basis. As a result, increasing interest in studying this trend and in understanding its key characteristics has developed. As noted by Zou and Cavusgil (2002) a number of different approaches have been adopted, which vary in terms of their theoretical or conceptual underpinnings, and focus on different facets of marketing strategy as well as their definition of terms such as *global* and *marketing strategy* (see GLOBAL MARKETING STRATEGY). This has resulted in the absence of a generally accepted conceptualization of global marketing strategy, and hence, an ability to generalize findings from different research studies and more broadly improve understanding with regard to the impact of globalization on the firm's competitive position.

In this article, a framework is presented that aims to provide a clear understanding of global marketing strategy and at the same time allows incorporation of other perspectives. First, the different terms that are used in the present article are explained. Next, the dominant approaches to studying international/global marketing and the theoretical perspectives that underlie these approaches are briefly reviewed and the key topics covered. The various issues confronting the firm as it develops a global marketing strategy are then discussed, starting with the initial development of the strategy, followed by the ongoing process of refining and developing that strategy and consolidating the strategy to improve efficiency and competitiveness in global markets.

Key concepts.

Global. The term *global* is used to define the geographic scope of the firm's operations and strategy development. A firm is considered to have a global marketing strategy if it is

involved in marketing its products and services in most geographic regions and areas in the world, has established a clear strategy as to how these operations are managed in each of these areas, and retains control over how these operations are managed and evaluated (see GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES). This does not necessarily imply that these operations are globally integrated or standardized on a worldwide basis. The term *global* will be used broadly to refer to any involvement outside the firm's home market, as global strategy must start somewhere.

Marketing strategy. A *marketing strategy* is defined as a strategy that is based not only on identifying target customer needs and interests in a clearly defined product market in order to develop customer value creation but also in clearly identifying the firm's distinctive skills and capabilities relative to those of other competitors in the marketplace (see COMPETITIVE ADVANTAGE: ITS SOURCES AND THE SEARCH FOR VALUE). This results in the development of a marketing strategy based on the firm's competitive advantage and skills in relation not only to marketing activities such as new product development, pricing, advertising, and distribution, but also to other elements of the value chain, both upstream and downstream such as design, production, sourcing, and logistics.

ALTERNATIVE APPROACHES AND PERSPECTIVES TO GLOBAL MARKETING STRATEGY

In studying global marketing strategy, a number of different approaches have been adopted ranging from the transaction cost perspective to the evolutionary and global integration perspective. Typically, each focuses on different decisions or aspects of global marketing strategy and corresponds in many respects to differences in the experience of the firm in international markets.

The transaction cost approach. One of the earliest approaches adopted in studying the development of global marketing strategy was transaction cost analysis (Anderson and Gatignon, 1986). This focused on the

2 global marketing strategy: perspectives and approaches

appropriate choice of mode of entry into international markets and viewed such decisions as a trade-off between control and the cost of resource commitments, and was grounded in Williamson's (1981) transaction cost economics. While control enables the firm to coordinate actions, execute and revise strategies, and thus obtain a higher return, it also entails commitment of resources and hence exposure to risk in an uncertain environment. This perspective has subsequently been widely used in assessing mode of entry decisions (Erramilli and Rao, 1983), notably for exporters and service firms.

The standardization/adaptation perspective.

The standardization/adaptation issue (see STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY) was initially raised by Buzzell (1968), examining the potential benefits of standardizing different elements of the marketing mix as opposed to adopting localized strategies. This became a central debate characterizing the marketing literature following Levitt's controversial article "The Globalization of Markets" Levitt (1983), which argued that multinational firms would only be successful if they marketed standardized products worldwide, taking advantage of potential economies of scale in production, distribution, marketing, and management. This debate has been widely pursued not only in relation to marketing strategy in general (Douglas and Wind, 1987) but also in relation to the benefits and feasibility of standardization relative to different elements of the marketing mix, products, and target segments (Jain, 1989).

The global configuration/coordination perspective. This perspective emphasizes the importance of configuring and coordinating the firm's activities at different stages in the value chain across different countries so as to improve efficiency and gain the maximum competitive advantage (Craig and Douglas, 2000; Takeuchi and Porter, 1986; Roth, 1992). Activities at the upper end of the value chain such as sourcing, design, and engineering should, for example, be concentrated in countries where they can be performed most effectively and cost efficiently. At the same time, activities

should be both vertically and horizontally coordinated at different stages in the value chain and across countries to optimize cost efficiency and maximize speed of response to changes in demand or competitor moves.

The global integration perspective. Another perspective is the global integration approach (Yip, 1995; Zou and Cavusgil, 2002). World markets are viewed as an integrated whole, and emphasis is placed on the importance of conducting operations in all major markets worldwide, and integrating strategy development and execution across these markets (see FORCES AFFECTING GLOBAL INTEGRATION AND GLOBAL MARKETING). Similarly, resources may be shifted from one market to another in order to compete more effectively. For example, competitive attacks in one market may be met by counterattacks in a competitor's home market or other key markets. In addition, emphasis is placed on developing a strategy for the standardization of product, promotion, and distribution activities across world markets.

The evolutionary perspective. The most comprehensive perspective is to view the firm's operations as evolving over time as the firm gains experience and expands in international markets. The "stages" theory of internationalization developed by Johansson and Vahlne (1977), based on a study of the pattern of internationalization of Swedish firms, argues that the perceived risk associated with international expansion leads firms to enter proximate, more familiar markets first, gradually expanding into more distant market as experience is gained in operating in international markets. Similarly, Douglas and Craig (1989, 1995) suggest that international market expansion can be viewed as a sequential decision-making process starting with decisions relating to entry into international markets, standardization versus adaptation of international marketing mix decisions to different environmental conditions, and subsequently focusing on coordination and integration of these decisions across national markets.

More recently, it has been pointed out that some firms are "born global" (Knight and Cavusgil, 1996, see BORN GLOBAL). In essence,

such firms immediately adopt a global perspective in initial market entry, and target customers worldwide. Typically, these firms target “niche” markets where customers in different countries have similar needs and interests, for example, medical equipment and computer software. The growth of the international communications infrastructure, particularly, the Internet, often facilitates identification of these opportunities and establishment of relations with customers, ensuring that customer needs are met and satisfied on an ongoing basis.

Since the evolutionary framework also provides the broadest perspective and can also incorporate the other perspectives, this article also focuses on the specific decisions that a firm needs to make as it develops experience in international markets.

BEGINNING GLOBAL MARKET OPERATIONS

While not all firms expand operations to the point where they can be considered global, all begin by entering a country or countries outside their home market. In initially entering into global markets, a firm needs to make three key decisions:

- which countries to enter;
- what modes of operation to adopt; and
- the timing and sequencing of entry.

These decisions need to be considered in the light of the firm’s objectives with regard to global markets, particularly with regard to the desired degree of involvement, and amount of resources (human and financial) a firm is willing to devote to developing operations in international markets, as well as the level of risk – macroeconomic, competitive, and policy – that it is willing to consider in going international.

Selecting countries to enter. In deciding which countries to enter (*see* MARKET ENTRY AND EXPANSION), the firm needs to first evaluate opportunities on a worldwide basis, assessing in each country the macroeconomic environmental factors, such as population size and growth, the level of GNI (Gross National Income) and rate of economic growth, the degree of urbanization, the rate of inflation, the level of corruption, political risk, financial risk, trade barriers, and

market regulation. In addition, opportunities and risk at the product market level need to be assessed. Here, the firm needs to consider the absolute size of the product market and its rate of growth, as well as per capita consumption and growth. If a product is not currently marketed in a country, surrogate indicators of demand need to be used. The level of competition also needs to be considered as also the presence and strength of other global, regional, and local competitors. Markets that are large may appear attractive, but if the rate of growth is low this may signal that the market is saturated. Similarly, the market may have a high rate of growth, but if there is a substantial degree of competition, the firm may prefer to focus on developing operations and stimulating primary demand in a less competitive market. In conducting this analysis, a hierarchical screening process based on secondary data can be used to assess opportunities worldwide in order to reduce and expedite the assessment of opportunities and risk.

Mode of operation. Once having assessed opportunities and determined which countries to enter or consider entering, the firm needs to consider the mode of operation, that is, whether to enter via exporting (*see* EXPORT PERFORMANCE), a contractual agreement with another firm such as licensing or franchising, contract manufacturing, or joint venture, or alternatively, to set up a wholly owned subsidiary either on a greenfield basis or via acquisition. Here, a key factor is the degree of control a firm wishes to exercise over operations in international markets as well as the importance of local input and experience in managing and developing operations, and the resources a firm is willing to devote to international expansion. Some firms, for example, wine or agricultural producers, have no choice but to export if they wish to enter international markets. Similarly, service operations, for example, fast food, hotel chains, and car hire typically expand via franchising to avoid the cost of acquiring local facilities and to ensure input of local management capabilities and experience (*see* INTERNATIONAL FRANCHISING). This, however, typically requires extensive systems of control and training on a global or regional basis to ensure that franchisees in all markets provide

4 global marketing strategy: perspectives and approaches

a consistent service experience and reinforce the firm's brand image internationally.

Timing and sequencing of global market entry. The firm also needs to decide the *timing* of its entry into different international markets, that is, whether to be a first mover and enter a country ahead of competition, or alternatively be a fast follower (see INTERNATIONAL PRODUCT DIFFUSION). Being a first mover enables the firm to establish its brands and develop customer and distributor loyalty ahead of competition as well as to monopolize key resources such as strategic locations, key distribution channels, thus erecting entry barriers for competition. On the other hand, being a first mover also entails substantial risks as the firm needs to expend resources to stimulate primary demand and in some cases, develop the market infrastructure besides convincing distributors to stock the product. Similarly, there is substantial uncertainty as to whether potential demand will develop or whether environmental conditions will change, for example, the imposition of product regulations. Similarly, competitors can learn from the firm's mistakes and "leapfrog" the learning curve, entering later with a more desirable product or effective marketing strategy.

Another aspect is the *sequencing* of market entry. A firm may decide to enter international markets sequentially, adopting, for example, a "rehearsal" strategy, entering one country in a region first to gain experience in that market, then rolling out into other countries. For example, a US firm entering the European market might decide to enter the Netherlands first, and use that experience to develop strategies for entering other large markets in Europe, for example, France, Germany, and the United Kingdom. A variant of this strategy is to enter a single country in each region first and use this as a base for developing operations and strategy in other markets in the region. For example, McDonalds first entered into the United Kingdom, and then expanded into the rest of Europe, and used Australia as a basis for developing operations in Southeast Asia.

A key factor driving strategy in initial entry is the desire to achieve *economies of scale*. Typically, a firm will use the same

marketing strategy, particularly in terms of products, product positioning, and branding in international markets as in domestic markets so as to achieve *tangible and intangible* economies of scale. *Tangible* economies typically arise from production economies of scale or spreading R&D and other investment costs, for example, in developing advertising themes and copy, over a larger volume of sales. *Intangible* economies may be less apparent, arising from use of the brand or corporate image on an international basis, thus enhancing its visibility and value to customers. Other intangible economies may include specialized management skills and know-how, for example, in the management of franchise operations or the development of creative product and marketing ideas as in Apple's product design capabilities, or Bic's skill in developing disposable products.

While many firms, both large and small, have already entered international markets, typical firms that are still in the early stages of entering international markets are

- *entrepreneurial firms* (see INTERNATIONAL ENTREPRENEURSHIP), often targeting niche markets worldwide, for example, firms selling specialized medical equipment, export services, or new product variants such as soft serve ice cream;
- *large emerging market multinationals* that often enter markets in developed countries with a low cost positioning based on resource cost in their home market, for example, Haier, a Chinese consumer electronics firm; or Embraer, a Brazilian manufacturer of small jet aircraft; or Mahindra and Mahindra, an Indian manufacturer of agricultural equipment.

REFINING AND DEVELOPING GLOBAL MARKETING STRATEGY

Typically, once firms have entered a number of countries, they begin to expand within these markets. This is stimulated in part by concern with meeting local competition and meeting specific local needs and interests. This is further reinforced by local management attitudes and initiatives that typically reflect a belief that

local market characteristics and demand conditions are different and require adaptation of products and marketing strategy. An important concern is also more effective utilization of local knowledge and assets resulting in product line extension or development of new products that can make use of existing channels of distribution. Constraints imposed by national market barriers, for example, tariff barriers, quotas, import duties, and local product regulation, may also encourage local production.

In entering and expanding within countries that the firm has decided to enter, the following three decisions are of paramount importance:

- how far to market *standardized products worldwide* or adapt to differing conditions in different countries (see STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY), and similarly, whether to adopt the same marketing strategy, that is, pricing, promotion, and distribution strategy or to adapt locally;
- whether to *extend the product line* to include local variants adapted to local customer demand and market conditions;
- whether to *develop new products* to meet specific local needs, for example, in emerging markets or markets with different climatic conditions (see INTERNATIONAL PRICING OBJECTIVES AND STRATEGIES; DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES).

In considering whether or not to standardize or adapt different elements of the marketing mix, the firm needs to consider a number of different factors. While there are a number of benefits from standardization, there are also barriers to standardization and advantages to adapting, and these need to be weighed relative to each element of the marketing mix. Some mix elements such as product and how it is positioned may be more readily standardized than other elements such as pricing (see INTERNATIONAL PRICING OBJECTIVES AND STRATEGIES) or distribution (see DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES). Similarly, the degree of modification may vary ranging from minor modifications such as adjusting to voltage, size

or color preferences, to major differences such as taste and technological complexity.

One of the primary *benefits of standardization* is that firms are able to achieve economies of scale in R&D and production. Product standardization in international markets enables a firm to reduce the number of models worldwide and hence reduce development costs in addition to enabling them to afford a higher level of design expertise. Similarly, pharmaceutical companies are able to spread the high cost of developing new drugs, and consumer goods companies the costs of advertising (see INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?) development across a higher sales volume. Standardization also enables firms to transfer ideas, experience, and knowledge developed in one market to other markets, for example, the concept of disposable products, or experience in developing environmentally friendly products and packaging (see GLOBAL CONSUMERISM AND CONSUMPTION). Standardized products also facilitate the development of a uniform image of quality and service and the ability to develop a strong corporate or brand image worldwide. Standardization also facilitates coordination and control of operations in different country markets as uniform performance standards can be established and performance more readily compared across countries.

On the other hand, there are a number of *barriers to standardization*. Differences in customer characteristics and response patterns caused by different sociocultural values and lifestyles, climatic or usage conditions, or perceptions and associations with different images, may generate need for different products, or promotional and distribution strategies. Similarly, government regulations and restrictions relating particularly to product and promotional decisions, or campaigns to buy local products, may result in the need to adapt product positioning and promotional strategy. Likewise, differences in the marketing infrastructure, for example, the availability, cost, and effectiveness of different media such as TV, radio, and print as well as nontraditional media, such as the Internet or viral marketing have to be accounted for. Similarly, the organization of the distribution infrastructure and the importance of large-scale

distribution organizations versus small Mom and Pop stores may vary considerably from one country to another, or the presence of international or regional retailers may vary considerably, facilitating or hindering local brands and products. Similarly, the extent of and strength of local or regional competitors may vary. Typically, the presence of strong local competition will create pressures to adapt either in terms of product, promotion, or pricing strategy. In addition, local managers are typically opposed to standardized products as these reduce their control over marketing strategy, as marketing policy and guidelines are likely to be established at regional or corporate headquarters.

Such differences in market and demand conditions in different countries and regions, typically lead the firm to *extend the product line* adding new product variants that are adapted to specific needs and tastes (*see* MANAGING THE GLOBAL PRODUCT PORTFOLIO). This may include adding product versions with new flavors or scents, or different types of soft drinks, or bottled waters. This typically helps to generate additional sales, fills out the firm's product line, and enables the firm to tap a broader range of customers as well as compete more effectively in the local marketplace.

At the same time, the firm may also *develop new products* tailored to specific local market needs (*see* INTERNATIONAL PRODUCT INNOVATION AND DEVELOPMENT). For example, in emerging markets the firm may develop simple functional products, for example, mobile phones targeted to low-income consumers who are unable to afford more complex high-end products marketed in developed countries. Similarly, computers that uses icons may be designed for illiterate consumers, and solar-powered equipment created for consumers with no or unreliable access to electricity. Again, this will help the firm's sales growth in a given market and tap a broader base of customers.

In extending the product line and developing new products within a given country, a key priority is to leverage *economies of scope*, adding products and product variants that can be distributed through existing channels of distribution or produced at existing production facilities. This enables the firm to spread overhead costs over a higher volume of products. At the

same time, it utilizes experience and knowledge of market conditions in a given country, and investment in research to identify and understand customer needs. Similarly, where the same channels of distribution are used, relations developed with distributors or sources of supply may be further reinforced. In essence therefore, a key aim is *building* the firm's operations in a given market, and particularly in building the scale and scope of operations so as to compete more effectively in local markets.

Firms focusing on refining and developing their international marketing strategy, are typically firms competing predominantly on a regional basis, for example, companies such as Henkel, the German-based manufacturer of detergents and other household products, as well as products targeted to handymen such as glue, paint, and solvents. Similarly, Kao, the Japanese detergent and personal products manufacturer, is focusing on growth in Southeast Asian markets. Other companies are transitioning from developing their strategy to consolidating their positioning and strategy across regional and global markets. McDonald's, for example, has rolled out local variants such as shrimp burgers and fried rice patties developed in Japan to other countries in Asia and McArabia flat bread in Europe. Similarly, in Europe many facilities are being upgraded so that customers come not only for fast service and inexpensive food, but also to enjoy a comfortable and clean environment. Other service ideas, such as home delivery started in Cairo, Egypt, are being added in other busy city centers.

CONSOLIDATING/INTEGRATING GLOBAL STRATEGY

A number of factors act as triggers to consolidate and rationalize operations across different markets (*see* FORCES AFFECTING GLOBAL INTEGRATION AND GLOBAL MARKETING). These include, for example, cost inefficiencies and duplication of effort across different country markets, particularly those that are similar in terms of demand characteristics or are geographically proximate. Similarly, opportunities may occur for the transfer of products and brands developed in one country market to other country markets, targeting similar market

segments, for example, high-income consumers, younger consumers, in business-to-business markets, or global customers. Similarly, the emergence of competition on a global scale is facilitated by improved linkages between national market infrastructures, for example, retailing or advertising media.

Such factors lead firms to pay increased attention to consolidating operations in global markets, and improving the coordination and integration of operations at different levels of the value chain, such as promotional efforts through greater use of regional or global media and positioning strategies or the establishment of global and regional product development centers. Similarly, sourcing or production strategies may be coordinated or configured at a global level. Here, however it is important to note that global configuration of sourcing and production strategies are dependent on standardization at the product design level.

A key element of the firm's strategy at this point is therefore to establish a *global portfolio of countries, products, and target segments* in order to establish direction for future efforts (see MANAGING THE GLOBAL PRODUCT PORTFOLIO). Then, it needs to establish global strategy based on the market scope and target market of its various product business, which may be focused on a specific target segment worldwide, or alternatively be broad based, targeting the mass market in different countries, or hybrid, that is, some combination of both. Finally, the firm will need to consider improved integration and coordination of operations both upstream and downstream in the value-chain as well as horizontally across geographic regions and product businesses.

In establishing the geographic scope of the global portfolio, the firm should maintain a balance between mature markets, such as the United States, Western Europe, and Japan, while targeting emerging growth markets such as China, India, Brazil, Thailand, or Colombia. The mature markets provide low growth, but also lower risk and require little additional investment to develop and build demand. The emerging markets, on the other hand, offer high growth potential, but require greater investment to understand customer demand, evaluate the nature of local competition, and build the market

infrastructure, particularly in underdeveloped regions. At the same time, the degree of integration across markets, for example, in Europe, South America, or the Indian subcontinent needs to be considered, in order to effectively allocate investment efforts within a region, as well as diversify across different regions of the world.

Once the firm has established the countries and regions to target, the next step is to establish the firm's GLOBAL MARKETING STRATEGY. Here, an important issue is how far this is integrated across different countries and regions of the world. This is likely to depend, to a substantial degree, on the scope of the product market. Where the firms adopt a focused strategy targeting a specific market segment, such as high-income consumers, or young adults, they are likely to integrate strategy across markets, adopting the same positioning, the same or similar product line and pricing, promotional copy and media, and distribution strategy. This may result in the use of global or regional media and, similarly, global or regional retailers who are able to provide coverage matching the geographic scope of the firm's operations and hence, improve marketing efficiencies. If, on the other hand, the firm targets a broad-based mass market, considerably greater difficulties may be encountered in integrating strategy across markets. While increasingly, many firms are adopting global branding strategies, the extent of the product line may vary from one region to another or even by country. Similarly, while advertising themes may be uniform across countries and regions, their execution may vary and distribution strategies may similarly need to be adapted to differences in the structure of the distribution system and the availability and reach of organized distribution, for example, super-markets, mass-market retailers, and department stores.

In integrating and consolidating strategy across countries and regions, a primary concern, as in initially entering international markets, is to achieve both *tangible and intangible scale efficiencies*, particularly with regard to the management of marketing and service operations. At the same time, *synergies* may arise from coordinating and integrating strategy and operations, especially across proximate markets, or in integrating communications

efforts at a regional or global level. Similarly, the *transfer of best practices* is critical, that is, ideas for products, promotional or distribution strategies across countries and regions, as well as experience and know-how in effectively managing marketing operations in different environmental conditions.

Many large US and European multinationals are in the process of consolidating operations across world markets. Many consumer goods firms, who previously had local or regional brands are focusing on building a global branding strategy, at the corporate, product business, and product level. In some cases, this leads to the development of tiered branding strategies where the product level brand is endorsed by the corporate brand as well as a family or house brand. Attention is also paid to building a global information system, particularly at the firm level so that production and distribution logistics can be better coordinated and integrated across countries and regions as well as across product businesses. Increasing emphasis is also paid to the transfer of management across geographic regions in order to enable them to develop experience in working in different environmental contexts, and hence develop and train a multi-cultural global workforce of managers capable of operating in a variety of different contexts. At the same time, they are able to bring their experience working in other countries and regions to deal with similar problems and situations in a given country or context.

ISSUES IN THE CONTINUING EVOLUTION OF GLOBAL MARKETING STRATEGY

The global marketing strategy of firms continues to evolve in response to a changing environment and new challenges. Three of the most pressing issues are (i) the *increasing complexity* of managing operations on a global scale; (ii) coping with the *increasing intensity of competition* not only from established multinationals but also from new competitors from emerging markets; and (iii) *exploiting opportunities in emerging markets*. The role of each of these in shaping the evolution of global marketing strategy is further elaborated.

Complexity of managing international operations. As international operations grow in

importance and complexity, management has to direct, coordinate, and control operations on a much broader and more diverse scale and scope (see MARKETING STRATEGY IMPLEMENTATION). This may entail decisions relating to the reconfiguration of the geographic organization of operations at different stages in the value chain, for example, developing global production platforms, or centers of product innovation, or improving vertical and horizontal coordination at different stages of the value chain as well as developing external communication linkages with customers, developing global account management systems, improved supplier linkages, and organizational restructuring to improve coordination and communication links across countries and regions. In addition, establishment of a global information system, and of a global management workforce, consisting of managers able to operate in different countries and cultural contexts are essential to operate effectively in increasingly culturally diverse and far-flung world markets.

Increasing intensity of competition. Firms have also to cope with the increasing intensity of competition as well as the emergence of new sources of competition. As growth slows in many markets in developed countries, such as the United States, Western Europe, and Japan, competition between established multinationals in these markets has become increasingly severe. This has been exacerbated by the entry of firms from emerging markets such as China, India, or Brazil. These firms are able not only to leverage the advantages of a low-cost resource base to build their position in global markets and enter developed markets but are also learning to adopt the technologies and management skills of firms in developed countries and in some cases surpass them in terms of innovative skills. Typically, these firms enter developed markets with a low-price positioning. However, often, as they establish a market position and effective distribution channels, they begin to move upward, adding higher-priced products and developing their brand image. This poses an increasing challenge to established multinationals in developed countries.

Exploiting opportunities in emerging markets.

Slower growth in developed markets has prompted firms to look to emerging markets for growth opportunities. Although current income levels in these countries are low relative to developed countries, ranging from \$4460 in Russia to \$730 in India, the growth rates and economic fundamentals in these countries suggest immense future market potential (see EMERGING MARKETS). Both India and China have sizable and relatively affluent middle classes which constitute a large market for goods and service as well as vast markets of rural poor and an increasing number of highly successful entrepreneurs. Here, an important decision for developed market firms is whether to focus on the affluent urban middle class in these countries, leveraging existing products and global brands, with limited adaptation of the marketing mix, or alternatively, target lower income consumers, typically in rural areas. Targeting lower income consumers, however, typically requires the development of radically new marketing strategies, including the development of new low-cost functional products and improvement of distribution access and efficiency in rural areas. In addition, creative ways to enhance the ability of consumers to afford products need to be developed. While requiring substantial effort and ingenuity, the size and potential of the emerging markets, not only in India and China but also other continents such as South America and Africa, offers tremendous opportunities for future growth.

CONCLUSION

The crafting of global marketing strategy is a dynamic ongoing process, continually evolving as the firm expands into new countries and markets, requiring adaptation to new market conditions and demand factors, competitive forces, as well as internal pressures within the firm. Also, the fundamental nature of global marketing strategy changes as the firm's involvement in global markets increases. To succeed, the firm must become an organism that continually evolves, adapts, and responds to the changing realities of the global marketplace. Firms that are able to do so will prosper; those that do not will wither.

digital medium and global marketing

Venkatesh Shankar

INTRODUCTION

The digital revolution is transforming the business landscape and profoundly influencing marketing in an increasingly global environment. From a demand perspective, the digital medium or the Internet (e.g., World Wide Web, email) has offered firms access to new customers, markets, and business models across the globe. From a supply standpoint, the digital medium has enabled firms to cut costs of marketing and operations by coordinating their value chains around the globe. In this article, we focus on the role of the digital medium or the Internet on the global marketplace and global marketing.

The role of digital medium or the Internet in global marketing decisions and the impact of the Internet on firm performance in global markets can be analyzed through an organizing framework (Shankar and Meyer, 2009). This framework addresses the following important questions. How does the Internet affect a firm's global marketing decisions? What are the direct and indirect effects of the Internet and Internet marketing strategy on firm performance in global markets?

Companies use the Internet in the global marketing context in different ways. Firms can use the Internet for gathering information, providing customer support, and improving customer relationships. Some firms use the Internet as a primary information source and information dissemination vehicle to perform global market research and to identify customer segments that span different countries. Others use it as a medium for communicating a brand's value proposition or position to its target audience across countries. Broadly speaking, companies use the Internet to formulate and implement global marketing mix decisions.

Shankar and Meyer's (2009) organizing framework relating to the Internet, global marketing decisions and firm performance is shown in Figure 1. The global/international marketing mix decisions include those on product, brand, price, communication, promotion, and distribution channels. The Internet

and Internet marketing strategy directly influence both the global marketing mix decisions and the firm's performance. The Internet and the Internet marketing strategy of a firm also have moderating effects on the impacts of each global marketing mix decision on firm performance. Because firm performance is critical to firms, we focus on the direct and moderating effects of the Internet and Internet marketing strategy on firm performance.

In formulating their global digital marketing strategy, firms can compare different countries on dimensions such as infrastructure, geographical distance, language, buyer behavior, buyer demographics, country image, payment systems, and currency using a framework based on two dimensions: global integration and local responsiveness (Guillen, 2002). Depending on the combination of these dimensions, he recommends four global Internet marketing strategies: pure local adaptation, global cost leadership, nationally differentiated, and transnational cost adaptation strategies. According to him, each strategy is appropriate for specific product categories. According to him, for example, products whose features are most amenable to direct inspection, such as clothing, cars, and collectibles should follow a nationally differentiated strategy because these categories need high local responsiveness in website design, language, return policy, and customer service, but low integration across countries. The framework is useful for classifying different categories but offers few guidelines on leveraging the digital medium in the global marketing context.

DIGITAL MEDIUM AND GLOBAL PRODUCT DEVELOPMENT

The Internet is increasingly used in global product development. Companies can use real time collaboration software for product design so that product developers across the globe can connect and simultaneously work on the same product idea. A driving factor for using the Internet in global product development is shorter design cycles fueled by the opportunity to develop products on a 24 × 7 basis globally. Companies use global Web-based design platforms to develop products through collaborative teams across the world. The primary benefits

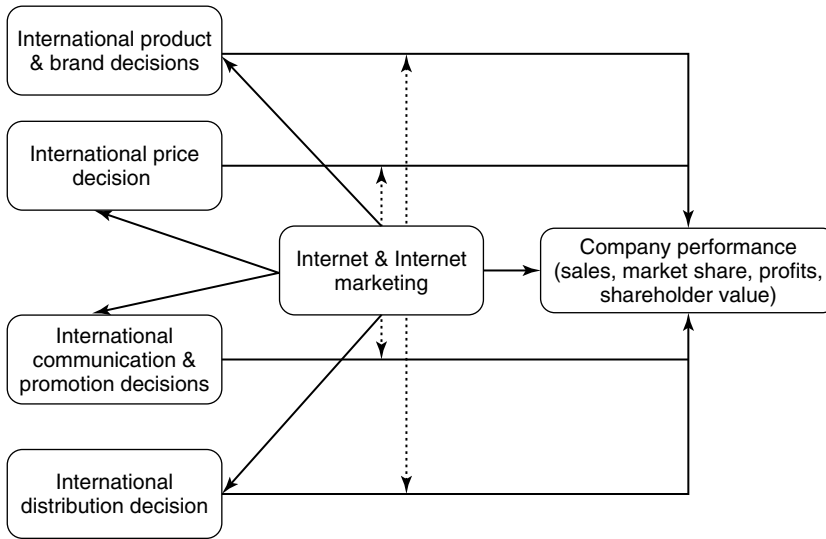

Figure 1 An organizing framework for Internet and international marketing. (Bold lines represent direct effects. Dashed lines represent moderating effects.) Source: Shankar and Meyer (2009).

of Web-based global product development are reduced product development time, greater ideas and inputs from design engineers around the world, and better time-leveraging of talent located at different time zones. Some companies also use these Web-based systems to work across the globe with “offshoring” partners.

The Internet also plays an important part in the diffusion of a new product within and across countries. For products such as pharmaceutical drugs and movies, the Internet serves as a powerful medium to inform potential users and customers across countries. On the one hand, firms can leverage this information dissemination ability of the Internet to accelerate the diffusion of their products across countries. On the other hand, if customers in the initial markets had adverse experiences with their products, firms may be hampered by the Internet in new global markets. Therefore, firms need to more carefully plan the design and management of product launches in the initial markets.

To sum up, the Internet has an important role to play in product development across countries. Managed appropriately, the Internet can result in better new product ideas, more effective collaboration, shorter development cycle

time, and better use of talent across multiple time zones. The Internet can play both positive and negative roles in the diffusion of new products across cultures and countries. Hence firms will have to more carefully plan their product introductions in the initial countries.

Digital medium and global communication. The Internet plays a key role in companies’ communication and promotion efforts and in their effectiveness in the global marketplace. Communication efforts can be of two types: company-generated and user-generated. Company-generated communication efforts are typically centered on company websites. User-generated communication efforts relate to activities such as the creation and management of social media, community sites, blogging, and file sharing by customers.

Company-generated communication. Culture affects customer attitudes toward company websites, and hence has a strong effect on website effectiveness. Most companies have country-specific websites. For example, Procter & Gamble created regional sites during the 2006 World Cup soccer championship to promote its Gillette, Braun, Duracell, and Oral B brands

and to raise awareness of its status as an official sponsor (Shankar and Meyer, 2009). Users from several countries first selected one of the four geographical regions on its website and then had the option to choose the language in which the website appeared. Research suggests that local language and local adaptation are keys to the success of global marketing on the Internet.

An important strategic issue related to the Internet in the global context is the globalization versus localization of products and websites. Globalization refers to the standardization of products and sites across countries and cultures, while localization refers to the adaptation of products and sites to different countries (Shankar and Donato 2003). While companies should naturally adapt their websites to local languages, the extent to which they should adapt the website content to the individual countries would depend on the product development and marketing costs, culture-specificity of products, importance of brand equity, and the degree of country-specific customer needs.

User-generated communication. The Internet enables users to share information and create global communities focused on specific topics. User-generated communication in the global context can be classified into different forms: posting on social media such as Facebook, MySpace, Twitter, and LinkedIn; blogging on own as well as community global sites; podcasting; posting videos on video sites such as YouTube and Flickr; and posting product reviews in global communities. By measuring and monitoring such communication about the firm and its products, a firm can use the information to better manage its relationship with its customers and improve its products and customer service. For example, before the launch of PlayStation 2, a global brand community that allowed consumers to discuss and anticipate attributes of the new product had emerged. However, because the Internet also allowed “brand terrorists” (users who can control a brand in ways detrimental to the firm owning the brand), Sony decided to launch its own global brand community so that it could monitor and proactively listen to the conversations among consumers. Another example is Stormhoek winery in South Africa.

Through the use of various online marketing activities, including blogging, Stormhoek increased its shipments to the United Kingdom from 50 000 cases in 2005 to 350 000 cases in 2007 (Business Day, 2007).

Another example of a global online brand community is NikePlus, designed with music collaboration from Apple, that offers an array of useful tools for running enthusiasts. These tools include managing own runs, issuing running challenge to friends, socializing with other community members across the world, obtaining music through Apple, and sharing information through blogs.

To summarize, the Internet moderates the effect of communication and promotion on firm performance in the global context. By better understanding customer needs across different countries and cultures, firms can develop appropriate content on their websites in different markets. They could also measure and monitor user-generated communication and proactively use the information for improving products, enhancing customer service, and deepening customer relationships.

DIGITAL MEDIUM AND GLOBAL PRICING

The Internet affects prices and their dispersion across sellers. The Internet has allowed different segments to become aware of prices offered to one another, regardless of where the segments are physically located. For example, the pricing of pharmaceuticals in Europe is changing such that price differentials across countries are narrower because consumers know that the price of a drug in Spain is different from that in Belgium. Sometimes, online price dispersion across countries may be influenced by regulatory authorities. Consider the case of pricing of Apple's *iTunes* in Europe (Sweeny, 2008). Until 2008, the prices for downloading a song or album through *iTunes* were higher in the United Kingdom than in 16 other European countries. For example, in France and Germany, music buyers were charged €0.99 (74p) per track, while British music fans were charged 79p. Following consumer complaints, the European Commission investigated Apple for unfair pricing. In early 2008, Apple agreed to reduce the price it charges UK users to buy

4 digital medium and global marketing

tracks from *iTunes* by almost 10% within six months to bring them in line with the rest of Europe. Although Apple finally made the decision to follow a harmonized pan-European pricing policy, its ability to do so also depends on the willingness of the major record labels to adopt a pan-European standardized view of pricing.

These examples highlight the role of price transparency in firms' pricing strategy across global markets. Although the Internet has brought increased transparency on costs and prices, it has also allowed firms to highlight and differentiate on nonprice attributes (Shankar, Rangaswamy and Pusateri, 2001). It is possible for firms to tailor their offerings to the needs of consumers in different countries or offer branded variants across countries, thus reducing the inclination or ability of customers to directly compare prices of the same item across countries.

Owing to such possibilities, there are differences among prices and dispersion of prices among retailers across different countries. Ancarani *et al.* (2008) argue that on the one hand retailer price levels and dispersion may be similar across countries because channel competition and the roles of channels are increasingly similar across countries and the borderless nature and transparency of the Internet can have a positive influence on the similarity of retailer pricing across countries. However, on the other hand, they suggest that retailer price levels and dispersion may be different across countries because of differences in the adoption rate of the Internet, consumer attitudes toward the Internet, price sensitivities, and competitive landscape across countries.

Ancarani *et al.* (2008) present an empirical analysis of retailer price levels and dispersion using data collected for different product categories (e.g., books, CDs) in three European countries, namely, France, Germany, and Italy. Their results show that, in general, price levels, including shipping costs, are higher online than offline in each of these three countries and that price dispersion is persistent across these countries. Multichannel retailers have the highest price levels in each of these countries, but they do not exhibit the highest price dispersion. Their results suggest that the opportunities for price differentiation for a given type of retailer may

be different in different countries. Their data, however, are restricted to two product categories in three Group 7 (G7) countries and may not be generalizable across developing economies.

Thus, consumer and company use of the digital medium have important influences on firm prices and on the effect of pricing on firm performance. The Internet enhances price transparency and allows customers to compare prices across countries. However, empirical analysis of price levels and price dispersion suggests that price dispersion is persistent, and the opportunities for price differentiation do exist and may be different across countries.

DIGITAL MEDIUM AND GLOBAL CHANNELS

The Internet serves as a distribution channel for many firms for several products. It often acts as a direct distribution channel for marketers of items ranging from apparel to computer hardware and software to books to CDs and DVDs to electronic equipment. In some cases, the Internet serves as a substitute channel for other distribution channels such as physical stores and catalogs. In other cases, it acts as a complementary channel. The use of the Internet as an important distribution channel in the emerging practice of multichannel marketing is growing.

In the global context, the use of the Internet as a distribution channel is significant because it allows many firms to reach a wide global audience without substantially increasing the cost of channel development. However, the practice of multichannel marketing in the global context depends on the degree of substitute or complementary effects of the Internet relative to other channels in each country. In countries where the complementarity of the Internet with other channels is high, firms will practice greater multichannel marketing than in countries where the Internet is perceived as a substitute to other channels.

A firm's extent of use of the Internet as a distribution channel in each country may depend on the country, customer, company, and competition factors. The country factors include regulatory issues, taxes, transportation modes, geographical proximity of the country to fulfillment center, Internet penetration level, and logistical infrastructure. Customer factors

include desired delivery speed, willingness to pay, the extent of physical inspection desired, and the influence of consumer-generated digital media. Company factors comprise market reach goals, distribution competency, fulfillment capability, shipping costs, and the like. Competition factors include the number and intensity of competitors in that country, the distribution channels of competitors in the country, channel expertise of competitors, and anticipated channel moves of competitors (Shankar, Rangaswamy and Pusateri, 2010a, 2010b). Depending on the combination of these factors, a firm may tailor the extent of the use of the Internet as a distribution channel for different countries.

The evidence for the use and success of the Internet as a distribution channel in the global context, however, is mixed. While many firms use their websites as store fronts to customers in multiple countries and fulfill orders that they receive through their sites, because of the level of investment required by the clients, physical market presence and personal contact may be more important for sales. However, information designed for and placed on the Internet can improve a firm's reputation and credibility, making personal selling easier in global markets.

The example of Stormhoek wines in South Africa illustrates how Internet can help global distribution for some types of products. By leveraging UK bloggers to sell directly to UK consumers, Stormhoek became "the wine of the blogging world." Stormhoek's shipments to the United Kingdom increased from 50 000 cases in 2005 to 350 000 in 2007 (Business Day, 2007). A well-designed channel strategy involving the Web across global markets will likely improve firm performance. However, apart from anecdotal evidence, there is sparse research on the effects of the Web as a distribution channel on firm performance across global markets.

In summary, there is mixed evidence on the use of the Internet as a distribution channel in global markets. The use of the Web as a channel depends on factors relating to country, customer, company, and competition. Although the use of the Web as a channel is likely to have a positive effect on firm performance in global markets, there is not enough evidence on this topic for us to make a strong conclusion.

FUTURE OPPORTUNITIES AND CONCLUSION

As Internet penetration in different countries continues to grow, the role of the Internet in global marketing will keep rising. The impact will be more significant and often more dramatic in countries where Internet penetration is still low and has enormous potential for improvement. In some countries, the ability of the Internet as a viable new medium of communication and channel of distribution can significantly impact economic growth.

A major development related to the Internet is the spread and rise of mobile media and technology across the world. Mobile devices such as cell phones, personal digital assistants, digital music players (e.g., iPod), and hybrid devices (e.g., iPhone, iPad) now provide more pervasive connectivity to websites and users through mobile Internet than ever before. Many developing countries are leapfrogging others in the use of the mobile Internet and email (through short-messaging service or SMS). For example, two emerging economic superpowers, China and India, are major beneficiaries of the surge of mobile Internet. China has the biggest user base of mobile phone subscribers, while India has the fastest growing mobile subscriber base (Shankar and Balasubramanian, 2009). Such rapid penetration of mobile Internet and connectivity will accelerate the impact of Internet marketing activities on firm performance across the world.

The rise in importance of the Internet and the mobile media in the global context offers several opportunities for future research on global marketing issues. Important questions in this regard are how does customer behavior with regard to the use of the Internet vary across countries? How do customers differ in mobile media usage across countries? How does the mobile Internet affect firm's marketing mix decisions? What impact does mobile Internet have on firm performance? What is the impact of user-generated communication among customers across diverse cultures on the diffusion of products across countries?

With regard to measures of firm performance, research on the Internet and global marketing has at best focused on company sales. Future research should examine measures such as profits and shareholder value. The availability of data on

Internet marketing activities in the global context will continue to be a challenge. In particular, because company data on costs and profits by country are confidential, it would be difficult to collect such data. Nevertheless, more empirical research in these areas will offer deeper insights into Internet and global marketing.

Not much is known on the differences between goods and services with regard to the role of the Internet in global marketing. Are the effects of the Internet on global marketing mix decisions and on the relationships between these decisions and firm performance the same for goods and services? In particular, are there differences between digitizable goods and digitizable services? Digitizable products (e.g., books, music, video, software) are those that can be easily distributed over the Internet to customers. In the global context, these products assume significance as they can be downloaded by customers in multiple countries any time. The *iTunes* is an example of such a digitizable product. With the launch and high initial sales of e-readers such as Amazon's Kindle, Barnes and Noble's Nook, and Apple's iPad, which offer advanced reading benefits, how should firms approach global marketing of print content? Future research could address these interesting questions and topics.

In conclusion, the explosive growth in the use of the digital medium continues to alter global marketplace and global marketing in important ways. The digital medium and global Internet marketing strategy have both a direct effect and moderating effects on the impact of marketing mix decisions on firm performance. With regard to global product development, the Internet has significant influences on the effectiveness and speed of new product development and its impact on firm performance. The Internet also has an important role in the effects of both company- and user-generated communication efforts on firm performance. On the global pricing dimension, the Web allows more pricing transparency, but also permits opportunities for differentiation across countries. With regard to global distribution, the Web may serve as either a substitute or a complementary channel in different global markets and by coordinating the Internet with other channels, firms can improve performance in global markets.

In the future, continued Internet penetration and the surging growth of mobile media may change global marketing further. Research on the digital medium and global marketing is still growing and many important questions remain largely underexplored. More research is needed to better understand the relationships among the Internet, mobile Internet, marketing mix decisions, and firm performance in the global context.

market entry and expansion

Keith D. Brouthers

INTRODUCTION

Although business expansion into global markets has grown rapidly in the past few decades, research in the area has lagged. Foreign market entry and expansion entails a number of important marketing strategy decisions including (i) selection of specific target countries, (ii) structuring of foreign subsidiary units, and (iii) management of foreign operations. In this article, we focus on the decision about structuring of international subsidiary units, often referred to as *entry-mode choice*. Research in this area has tended to focus almost exclusively on firm- and country-specific characteristics, showing little interest in the effects of marketing strategy, and managerial decision-making behavior (see INTERNATIONAL MARKETING CHANNELS). Brouthers and Hennart (2007) provide a detailed review of the entry-mode literature and suggest that scholars have tended to concentrate on rational models of strategic choice, ignoring behavioral aspects. Further, Canabal and White (2008) in their review note that most international entry-mode research has been published in international business and management journals with only a few contributions in marketing research outlets. This may explain why critically important issues involving marketing strategy have been virtually ignored by researchers so far.

International entry-mode choice, like other marketing strategy decisions, is influenced by a multitude of factors. These can be classified into three distinct groups (Figure 1): firm/country characteristics, top management team effects, and marketing strategy fit. The main theoretical perspectives that have been applied to the entry-mode decision – transaction cost analysis, resource-based view (RBV), and institutional theory – focus on firm and country characteristics. These theories do an excellent job of explaining how differences in country characteristics, such as institutional environments (Brouthers, 2002), and firm characteristics, like resource advantages (Brouthers, Brouthers, and Werner, 2008a), lead to specific entry-mode choices. What these theories and related

Figure 1 Dimensions of entry-mode choice.

research studies do not do is to help explain how marketing strategy issues as well as managerial decision-making processes and influences play a part in the entry-mode decision.

In this article, we provide a short overview of the existing entry-mode research and elaborate on areas where future marketing research can make an important contribution. Before we begin the review, we define some of the key terms and concepts that lie behind this research area.

KEY TERMS AND CONCEPTS

Entry modes – also referred to as *channel choice*, *channel selection*, *modes of entry*, or *entry structures* – vary along a continuum of risk and control (Brouthers and Hennart, 2007). At the high end are wholly owned subsidiary units where a firm owns 95% or more of the equity of the entity, and has made a large financial commitment, which exposes the firm to high risks, but also provides the firm with total control over the foreign operation. At the other extreme, are nonequity license agreements, where firms sell the right to use their product/process to a foreign-based firm, and exporting modes (see STRATEGIC EXPORT MARKETING–ACHIEVING SUCCESS IN A HARSH ENVIRONMENT). At this end of the spectrum, the firm has made only a small financial commitment and is therefore exposed to very low risk, but it also has little control over the foreign operation. Between these extremes are multiple variations including equity joint ventures (including majority, equal, and minority ownership), nonequity cooperative agreements (also commonly called

2 market entry and expansion

strategic alliances), and franchising agreements (a complex form of licensing) (see INTERNATIONAL FRANCHISING). As Canabal and White (2008) note, most studies exploring the entry-mode decision look at the choice between two or more of these mode types.

While exporting is an important entry mode, the marketing literature has tended to examine exporting channel selection as a decision separate from entry-mode choice. Scholars like Bello and Lohtia (1995) and others (see STRATEGIC EXPORT MARKETING—ACHIEVING SUCCESS IN A HARSH ENVIRONMENT) tend to use the same theoretical approaches in export channel choice as entry-mode scholars use in entry-mode choice. This tends to create some confusion among researchers because the exporting literature tends to be the only market entry and expansion literature where researchers separate the mode choice for the sales function of a firm from the mode choice of the production function of the firm. In fact, most entry-mode studies do not specify whether they are examining the entry for production, sales, or both functions of the firm. Hence, although the terminology is different (entry mode versus channel choice) the types of modes examined and the theories used in these two streams of research tend to coincide.

EXISTING RESEARCH

Firm and country characteristics. Most of the literature in entry-mode choice has been published since 1990. The growth in entry-mode (channel choice) scholarship since 1990 has provided researchers and managers with a better understanding of how firms choose between various entry-mode types. This research tends to use theories that focus attention on firm- or country-specific characteristics. For example, in Canabal and White's (2008) review they note that of the 10 most widely used independent variables, 6 are firm-specific (including international experience and firm size), and 4 are country-specific (including cultural distance and host-country risk).

Three main theoretical perspectives drive the study of entry-mode choice: transaction cost economics (TCE), institutional theory, and the

RBV (Brouthers and Hennart, 2007). TCE is the most widely applied theoretical perspective and captures both firm- and country-specific influences. TCE suggests that managers have limited cognitive abilities and hence are concerned with safeguarding their investments against issues arising from incomplete contracts and opportunism. This concern is amplified when the investment involves specific assets (a firm-specific attribute) as well as internal uncertainties (a firm-specific attribute) and external uncertainties (a country-specific attribute). These three characteristics of the transaction then influence the mode-choice decision.

Two recent meta-analyses of TCE entry-mode studies have found that asset specificity, internal uncertainties (also referred to as *behavioral uncertainties*), and external uncertainties (sometime referred to as *host-country risk*) all have a significant impact on entry-mode choice; providing strong support for the transaction cost perspective (Geyskens, Steenkamp, and Kumar, 2006; Zhao, Luo, and Suh, 2004). Further, these studies tend to show that foreign subsidiary performance is better when the mode used is predicted by transaction cost theory. This suggests that TCE can provide a good foundation for managers to develop a tool for determining the structure of new foreign subsidiary units that will result in greater success.

Furthermore, although TCE entry-mode choice models have been extensively tested on both service-based and product-based firms, normally, studies examine only product- or service-based firms, or include a dummy variable to "control" for this industry type. But these studies offer little insight into how decision-making and mode choice may differ between service providers that expand abroad and firms expanding to sell tangible products. There has been some progress in this area using TCE, but much more work is needed.

Probably, the most influential research study comparing service and manufacturing firm mode choice is the one by Erramilli and Rao (1993). They suggest that because services and manufactured products differ, transaction cost decision models of entry-mode choice need to be modified to take these differences into account. They go on to provide a theoretical extension to transaction

cost theory and test the revised theory empirically. Yet recently, Brouthers and Brouthers (2003) looked at the same issue and suggested that no adjustment to transaction cost theory was needed. They maintain that service- and product-based firms simply are influenced to a greater (lesser) extent by the basic transaction cost factors. They extend this work by suggesting the real difference between service- and product-based firms is associated with how risk and trust propensity influence mode choice and transaction-cost-based decisions.

In addition to transaction cost research, other studies have used an institutional theory perspective focusing on country-specific factors that may influence the mode-choice decision (Brouthers and Hennart, 2007). Institutional theory suggests that each country is composed of a unique combination of normative, cognitive, and regulative factors that impact the way business is carried out and how managers, employees, and customers behave. One stream of research in this area suggests that the institutional environment produces an isomorphic effect where firms simply replicate existing entry-mode structures to conform to industry or country standards. A second stream in this area suggests that the individual dimensions of the institutional environment (or the distance between home country and target country dimensions) have differing effects on mode choice; either creating opportunities for entry or restricting access to resources, customers, or distribution channels.

Originally conceptualized as national cultural distance and country risk, entry-mode studies tend to provide growing guidance on how the institutional environment impacts mode choice. The only meta-analysis in this area explores national cultural distance research (Tihanyi, Griffith, and Russell, 2005). This study finds that cultural distance does not tend to have a direct effect on mode choice but that it only has an impact on entry-mode choice for firms coming from high risk propensity countries (like the USA and the UK). This suggests that the cultural component of the institutional environment may have different effects for firms from different home countries entering different host countries. Other aspects of the institutional environment such as host-country risk and legal restrictions have also been examined, but as

yet no meta-analysis exists (see Brouthers and Hennart, 2007 for a summary of these studies). In general, research using institutional theory has provided managers with an understanding of how home- and host-country institutional factors influence the choice of entry mode and the success of foreign subsidiary units.

The third most widely used theoretical perspective, the RBV, focuses on firm-specific factors and generally suggests that firms are a collection of resources and capabilities (knowledge and processes) that can be combined in different ways to create a competitive advantage. This advantage can be used to help the firm enter foreign markets and overcome the liability of foreignness. Compared to both transaction cost and institutional-theory-based research, far fewer studies have examined entry-mode choice using the RBV because of the difficulty in defining and measuring resources, many of which, like tacit knowledge, are intangible (Brouthers and Hennart, 2007).

One of the more frequently explored resources that has been examined is experience. Scholars like Anderson and Coughlan (1987) and Delios and Henisz (2000) have noted that different types of experience may provide different benefits to the firm that can have an important impact on entry-mode choice (either in combination with transaction cost factors as noted by Anderson and Coughlan (1987) or moderated by the institutional environment as noted by Delios and Henisz (2000)). Some studies taking an RBV perspective tend to look at how foreign entry, and hence mode choice, can be used to exploit existing resources in new foreign markets while other research examines how the mode choices of firms can be used to help them scout for new resources to enhance the firm's existing stock. Research using this perspective has highlighted the importance of linking the type of resource advantage and motive for foreign expansion (exploitation of existing resource-based advantages or exploration for new resource-based advantages) with an appropriate subsidiary structure (Brouthers and Hennart, 2007).

In addition to studies using a single theoretical perspective, scholars often develop studies that combine multiple theories. For example, Brouthers, Brouthers, and Werner (2008a)

4 market entry and expansion

combine the RBV and institutional theory to examine their joint impact on mode choice. They find that resource-based advantages do not always have the same value in foreign markets as in the home market. Therefore, firms may need to vary their mode choice to get the most value out of existing resource-based advantages when entering foreign markets. Brouthers (2002) among others (Brouthers and Hennart (2007)) explore the mutual effects of TCE and institutional theory. They find that institutional theory helps extend TCE by clarifying additional external uncertainties that firms may face when entering new foreign markets. As Brouthers (2002) indicates, by considering both transaction cost characteristics as well as institutional factors, firms may make more informed mode-choice decisions that result in better performing foreign subsidiary units. Many other studies have combined aspects of two or more theoretical perspectives to examine the international entry-mode choices of firms. The one thing these studies all have in common is that they concentrate on theories that focus on firm- and country-specific aspects of the mode-choice decision (see Brouthers and Hennart (2007) for more details).

In sum, despite the growth in studies examining mode (channel) choice, most have used theoretical perspectives that focus on country- and firm-specific aspects of the decision. Although very helpful to managers, this research is limited because it means that we still have little understanding of how issues like marketing strategy or managerial biases influence the mode-choice decision.

POTENTIAL FOR FUTURE RESEARCH

There are now almost 200 studies providing theoretical and/or empirical examination of the issue of firm expansion and mode choice. Recently researchers have been questioning the need for further research in this area. Yet despite the growth in research there is still much to be learned. We now discuss two areas of research that have the potential to make a significant contribution to improving international performance through a better understanding of the method of entry-mode choice.

Marketing strategy. Marketing strategy deals with a wide range of decisions that can influence the performance of the firm (see GLOBAL MARKETING STRATEGY; GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES). Yet, when examining international expansion, researchers tend to ignore the marketing strategy implications of mode choice. Some research does address strategy issues. For example, Bradley and Gannon (2000) look at how market concentration versus diversification strategies impact mode choice while Sanchez-Peinado, Pla-Barber, and Hebert (2007) examine the impact of global versus multidomestic strategy, follow-the-leader strategies, and market-seeking strategies on mode choice. In these and related papers, researchers have found mixed support; strategies appear to provide an important impact on mode choice but the way that impact is felt is not entirely clear (Brouthers and Hennart, 2007).

Other marketing strategy issues have not found their way into entry-mode research despite their importance to the firm. For example, variations in product/service mix may have an influence on mode choice (see MARKETING MIX; MANAGING THE GLOBAL PRODUCT PORTFOLIO). Specific entry-mode types may enhance (detract from) the marketing effort in new foreign markets simply because of the product/service mix being offered. Normally firms do not use the same product/service mix in each foreign market as they use at home. These differences may call for different skills and knowledge, which may impact the mode-choice decision because different modes of entry provide firms with varying degrees of access to skills and knowledge.

Further, the marketing strategy of using standardized or adapted products/services in foreign markets may also influence mode choice (see STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY). Standardization, for example, may require few country-specific adjustments to the production process but extensive knowledge and skills in marketing the product/service to the final customer, hence influencing the mode choice for the production operation differently from the sales function. Likewise, adaptation of products/services may require extensive

country-specific production knowledge but might build on existing marketing skills. These differences may have a significant influence on mode choice and the effectiveness of the foreign operation.

Market orientation is now recognized as critically important in domestic markets, yet there is little understanding about the best way to extend this orientation to foreign markets (see MARKET ORIENTATION). A firm whose competitive advantage relies on its market orientation may need to think carefully about how to be successful in foreign markets. For example, is it more effective to use wholly owned subsidiaries and keep control of foreign operations when market orientation is important or does sharing ownership through joint ventures or license agreements help firms more effectively service foreign customers?

Branding strategy is also not considered in the mode-choice decision, yet brands are often one of the most powerful marketing tools a firm may possess (see BRAND STRATEGY; GLOBAL BRANDING: THREE KEYS FOR GLOBAL BRAND SUCCESS). Brands and brand strategy may significantly impact mode choice because brands may be better protected through some modes than through others. In addition, some mode types may make it easier for firms to obtain additional brands or expand brands to related products/services. Hence brand strategy may be another important determinant of the mode-choice decision.

As we have briefly outlined above, marketing strategy issues form an important and integral part of a firm's success, yet there is little understanding about the impact of marketing strategies on foreign market entry-mode decisions or how mode structure influences a firm's ability to effectively implement their chosen strategy.

Top management team. As we know from decision-making research the characteristics of the decision maker or decision-making team play a critically important part in determining what choices are made (Wubben and Wangenheim, 2008). However, in the entry-mode literature managerial influences are seldom included. There are a few recent papers that have started to look at the decision-making process using real-options theory (Brouthers, Brouthers,

and Werner, 2008b) and others that have examined manager characteristics (Brouthers and Hennart, 2007). But much more work needs to be done in this area.

For example, network theory has recently been used to help explain why managers make certain decisions (Rindfleisch and Moorman, 2001). Networks are the groups of individuals, both personal and professional, with whom the manager interacts, exchanges information, and shares resources. Researchers need to examine network connections, inside and outside the firm, to gain an understanding of how network relationships may influence the mode-choice decision. For example, do some networks discourage the use of specific entry-mode types or do some networks enhance the opportunity to use other mode types?

Organizational culture may also have a significant influence on the foreign market entry-mode choice decision. Firms may have cultural-based beliefs and values that eliminate certain mode choices from consideration or that influence the type of information that managers consider relevant to the mode-choice decision. Organizational cultural values can have an important impact on the decision-making process and outcome (Deshpande and Webster, 1989), yet entry-mode scholars have tended to ignore the impact of organizational culture in studies of entry-mode choice.

Furthermore, because foreign market expansion decisions are made at different levels of the firm, depending often on firm size, it is important that we obtain market entry decision data from the correct respondents. Studies looking at the impact of top managers in very large organizations, for example, may not be examining the right level of analysis. It is often the case in larger firms that SBU managers or product managers make these important expansion decisions. At present both marketing executives and middle managers have been conspicuously absent from entry-mode research. Obtaining data from these sources may be difficult but the value added could greatly increase our knowledge of how these decisions are really made.

As researchers in other areas have noted, managerial biases can have an important impact on the decisions they make. Those interested in foreign market expansion can help us gain

a better understanding of entry-mode choice by exploring the impact of factors that create biases in managerial decisions hence prohibiting managers from making the best entry structure decisions.

CONCLUSIONS

Although foreign market entry-mode scholarship has seen strong growth in recent years, there are still many unanswered questions. Even some of the most widely explored issues need further work as answers are still elusive as to the best way to make the entry-mode decision. Marketing practitioners and researchers can make an important contribution to our knowledge of market entry and expansion by focusing on how important marketing strategy issues and managerial biases influence these decisions.

In this article, we reviewed past research and highlighted several areas where new research is needed and where current research has failed us. By focusing on newer issues like market orientation, brand strategy, and product mix, researchers can help bring greater realism to our decision-making models. In addition, by gathering information from the appropriate level of manager in the firm and considering how issues like network relationships and organizational culture influence managerial decisions, future research can improve decision-making models that will help firms make better decisions in the future.

Finally, there are still enormous challenges ahead for researchers to gain a greater understanding of how market entry and expansion decisions are made. This expanded research can help facilitate better managerial practices and improve international performance for firms. Marketing scholars can have a substantial impact on this research by examining marketing issues and the influence of marketing managers in taking effective mode-choice decisions.

standardization/adaptation of international marketing strategy

David A. Griffith

INTRODUCTION

The appropriateness of standardization/adaptation of international marketing strategy has been a topic of importance to firms since the earliest times of international expansion. Most credit the stimulation of this debate to the practitioner realm in 1923 where a difference appeared between the approach to advertising by Goodyear's David Brown and Bausch & Lomb's Carl Propson. Brown (1923) viewed humanity as possessing common attributes, thus allowing for standardization. On the other hand, Propson (1923) argued that adaptation was often necessary to appeal to divergent local markets. Both approaches had their proponents and detractors with anecdotal evidence supportive of each.

The initiation of academic study on this important issue began in the late 1950s (Pratt, 1956), finding strong academic inquiry in the 1960s (Donnelly and Ryans, 1969), as the academic marketing discipline moved toward a more theoretical mode of inquiry. Since the initiation of academic inquiry on this topic, research on the topic has continued to proliferate and remains unabated (Donnelly and Ryans, 1969; Harvey, 1993; Szymanski, Sundar, and Varadarajan 1993; Onkvisit and Shaw, 1999; Griffith, Hu, and Ryans, 2000; Zou and Cavusgil, 2002; Ryans, Griffith, and White, 2003; Katsikeas, Samicee, and Theodosiou, 2006; Shoham *et al.*, 2008). Of the research that has been advanced, the vast majority of research presented prior to 1990 was conceptual/theoretical/anecdotal in nature. However, a significant number of empirical investigations have been put forth over the last 20 years (Cavusgil and Zou, 1994; Katsikeas, Samicee, and Theodosiou, 2006) that have provided a foundation for further clarification of this topic via the creation of contingency models.

DEFINING STANDARDIZATION/ADAPTATION

While a significant number of studies have been conducted on this important topic, an examination of a selection of seminal articles in the field demonstrates considerable divergence in foundational definitions. One such definitional concern relates to standardization/adaptation. For example, Jain (1989) defined *standardization* as a common marketing program on a worldwide basis. Szymanski, Sundar, and Varadarajan, (1993, p. 1) view *marketing-strategy standardization* as the "standardization of the pattern of resource allocation among marketing-mix variables across national markets." Alternatively, Cavusgil and Zou (1994) viewed the issue under the general "degree" of adaptation. Further, in integrating the standardization, configuration-coordination, and integration views, Zou and Cavusgil (2002, p. 42-43) conceptualize *global marketing strategy* (GMS) (*see* GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES; GLOBAL MARKETING STRATEGY) as the degree to which a firm globalizes its marketing behaviors in various countries through standardization of the marketing-mix variables, concentration and coordination of marketing activities, and integration of competitive moves across markets (*see* MARKETING STRATEGY IMPLEMENTATION; MARKETING MIX). Clearly, a consensus eludes researchers in the definition of this important topic. Lack of a consistent perspective on what constitutes marketing-strategy standardization/adaptation has created a fundamental limitation for advancement of research in this area.

Further inconsistencies can be viewed in relation to the definitional aspects of the outcomes of marketing-strategy standardization/adaptation. Specifically, the effectiveness of a firm's international marketing-strategy standardization/adaptation efforts is measured in terms of one performance aspect or another. For instance, Jain (1989, p. 76) argued that "standardization should be based on economic payoff, which includes financial performance, competitive advantage, and other aspects." Others, such as Cavusgil and Zou (1994), conceptualize performance as the extent to which a firm's objectives, both economic and

2 standardization/adaptation of international marketing strategy

strategic, are achieved through planning and execution. Others, taking a more consumer orientation (*see* CUSTOMER RELATIONSHIP MANAGEMENT), explored the acceptability to consumers of product attributes, messages (*see* INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?), brands (*see* BRAND STRATEGY; GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES), and so on. Still others, sidestep the issue of effectiveness by not conceptually defining it, but rather assuming it to be generally understood.

Given the diversity of conceptual definitions of both international marketing-strategy standardization/adaptation and the lack of consistency related to the conceptualization of the outcome effectiveness of marketing-strategy standardization/adaptation, it is not surprising that inconsistencies have been found within the literature relating to this issue (Onkvisit and Shaw, 1999; Zou and Cavusgil, 2002). This article does not work to resolve these conceptual distinctions but rather to address how differences in approaches to these distinctions have stimulated work in four key areas that are central to the understanding of the standardization/adaptation of marketing strategy: (i) type of standardization/adaptation, (ii) standardization/adaptation unit of analysis, (iii) market homogeneity and the effectiveness/efficiency argument, and (iv) models of standardization/adaptation.

TYPES OF STANDARDIZATION/ADAPTATION

Within both practice and research, standardization/adaptation of marketing strategy centers on two fundamental types: program and process (Sorenson and Wiechmann, 1975; Jain, 1989). Program standardization involves the tactical elements of marketing-strategy employment and is principally founded in the marketing mix, for example, product, place, promotion, and price (*cf.*, Cavusgil and Zou, 1994). As such, program standardization/adaptation examines whether specific elements of the marketing mix are consistent across markets. For example, differences in electric voltage for a product or the color used on promotional elements across

the United States and Argentina would be characteristic of program adaptations. Thus, a program approach to marketing-strategy standardization/adaptation looks to the inherent tactical execution elements of the firm's marketing efforts (such as pricing) across markets. Alternatively, process standardization involves the development of a common approach to the procedures underlying marketing-strategy activities, such as establishing (and evaluating) a distributor network (*see* SUPPLY CHAIN MANAGEMENT STRATEGY) and translating currency equivalents necessary for pricing (*see* INTERNATIONAL PRICING OBJECTIVES AND STRATEGIES) (Jain, 1989). A standardized process for, say, developing relationships is quite different from a standardized program (*i.e.*, specific management tactics to be used to administer the relationship) providing insights into the manner in which marketing strategy is developed and managed (*cf.*, Griffith, Hu, and Ryans, 2000). As such, process standardization/adaptation incorporates the procedural elements underlying the aspects of marketing strategy and tactics (*see* MARKETING STRATEGY; MARKETING STRATEGY IMPLEMENTATION).

While both program and process elements of marketing strategy are important to understanding a firm's success, the fact that program elements of a firm's marketing mix are more clearly observable and measurable has led to a research dominance on this aspect of marketing strategy when compared to process elements (which are typically not easily observable and highly variant across firms). Future research in this area will continue to address program and process issues (and hopefully the related nature of process and program standardization/adaptation) to gain a deeper understanding of this area.

STANDARDIZATION/ADAPTATION UNIT OF ANALYSIS

The unit of analysis of standardization/adaptation research has also been divergent. The unit of analysis specifies whether marketing-strategy standardization/adaptation is examined at a holistic marketing-strategy level, the individual marketing-mix element or

process level, or whether specific subelements within one of the marketing-mix elements or specific subprocesses of a marketing-strategy procedure are examined.

At the most aggregate level, marketing strategy is viewed holistically with all elements of the marketing strategy (*see* MARKETING STRATEGY MODELS; MARKETING STRATEGY) aggregated at the firm level (whether program or process) for the assessment of the firm's approach to marketing-strategy standardization/adaptation. For example, Zou and Cavusgil (2002) conceptualize the construct of GMS (*see* GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES) by aggregating across the firm's marketing activities working to understand, at the highest level, the influence of marketing strategy on firm performance issues. Current state-of-the-art findings related to this unit of aggregation are presented in a meta-analysis conducted by Katsikeas, Samiee, and Theodosiou (2006). Katsikeas, Samiee, and Theodosiou (2006) note that when observed at this level, stable performance implications are only obtainable when contingent factors are accounted for in the model.

The second unit of analysis investigated is the individual program or process related to a specific element of the marketing mix, for example, advertising strategy (*see* INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?), standardization/adaptation as a program element, or the procedures for developing advertising strategy as a process element. Researchers have often examined the individual marketing-mix elements and the degree of standardization/adaptation engaged in by the firm in respect of each marketing-mix element, such as promotion standardization/adaptation or channel standardization/adaptation. For example, Shoham *et al.* (2008) studied the behavioral and performance influences of international standardization of channel management (*see* INTERNATIONAL MARKETING CHANNELS), thus providing insights to the process of distribution management. Research at this unit of analysis, when investigating program elements, often aggregates aspects of the firm's marketing mix (e.g., product focus research investigating labeling, packaging, ingredients, etc.).

Lastly, researchers have argued for the need for fine-grained insights into how individual elements (either program or process) are employed. These scholars argue that practicing marketing managers employ the lowest level of analysis (i.e., decisions are made over every element of the firm product, inclusive of brand name, product specifications, packaging color, and size, etc.) and, as such, only through a detailed examination at the lowest level of analysis can a strong understanding of the implications and appropriateness of standardization/adaptation of marketing strategy be gained. For example, Griffith, Chandra, and Ryans (2003) explore individual elements of the promotional mix demonstrating unique performance implications in relation to each.

The extant research in this area demonstrates that unique insights can be gained from exploring each level. The future of standardization/adaptation research will continue to focus on all three units of analysis bringing forth new insights for academic inquiry and practical application.

MARKET HOMOGENEITY AND THE EFFECTIVENESS/EFFICIENCY ARGUMENT

The issue of the effectiveness versus the efficiency of the standardization/adaptation of marketing strategy resides in whether there is consumer homogeneity and/or the movement toward homogeneity (Donnelly and Ryans, 1969; Levitt, 1983; Walters, (1986); Samiee and Roth, 1992; Szymanski, Sundar, and Varadarajan, 1993; Zou and Cavusgil, 2002) (*see* CROSS-CULTURAL PSYCHOLOGY OF CONSUMER BEHAVIOR; SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE). Those researchers who view markets, or consumer wants and needs, as being homogeneous argue that the standardization of marketing strategy is more effective and efficient as it allows for the lowering of costs, via economies of scale, and thus increasing margins for a firm (Levitt, 1983; Jain, 1989) while simultaneously meeting the needs of the market. Alternatively, those who view markets as being heterogeneous, and therefore containing consumers with differing consumer wants and needs, perceive greater value delivery via adaptation of marketing-strategy elements

4 standardization/adaptation of international marketing strategy

(Donnelly and Ryans, 1969; Harvey, 1993), (the perspective here is that since consumer wants and needs are not homogeneous, efficiency under the standardization approach is an illusion). Despite its centrality to the focal research issue, the extent of homogeneity of markets for marketing-strategy standardization has been given little attention within the literature (this issue has primarily been the research domain of market segmentation without strong relation to the standardization/adaptation implications). Rather than focusing attention on market homogeneity directly, researchers have instead explored a number of consumer response elements believed to be important to GMS cross-culturally, such as brand loyalty (*see* CONSUMER BRAND LOYALTY), risk perception, and, most recently, brand personality. Given the disparity of consumer response in these studies, it appears as though the empirical evidence would contradict the argument for homogeneity of markets. However, it is important to note that firms often target very select markets (*see* MARKET SEGMENTATION AND TARGETING) and, therefore, consumer homogeneity often does (or can) exist at some level for the firms when a product is offered globally.

With underlying heterogeneity and homogeneity across markets, at least in some respect, the issue of efficiency and effectiveness of the standardization/adaptation of marketing strategy is evident. When homogeneity of markets exists, the standardization of international marketing strategy reduces costs by spreading costs over a greater number of markets, thus reducing average costs; the theoretical linkage is that lower costs achieved through standardization increases efficiencies while retaining the same level of “effectiveness” (where effectiveness relates to consumer response). Alternatively, where consumer heterogeneity exists, proponents of adaptation argue that international marketing-strategy adaptation that meets local consumer needs and wants is more effective (Harvey, 1993). While empirical support exists for the relationship between adaptation and performance, the issue of effectiveness of the adaptation of marketing strategy remains. For instance, could an adapted marketing strategy

be effective, yet not increase performance? Of course, it could depend upon the measures of effectiveness and performance one selects. A marketing strategy can have many differing objectives, for instance, increase brand awareness. The direct linkage between adaptation and performance may not be comprehensive – or at the least, fully explanatory (a recent meta-analysis by Katsikeas, Samiee, and Theodosiou ((2006)) provides substantive evidence for the need for a contingent approach to understanding the standardization/adaptation performance relationship).

Thus, when taken together, we can see that the effectiveness or efficiency of the standardization/adaptation of marketing-strategy decision is founded on consumer homogeneity/heterogeneity. With increased globalization (*see* SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE; GLOBAL CONSUMERISM AND CONSUMPTION), it is argued that some customer segments will become more homogeneous allowing for greater effectiveness and efficiencies offered by standardization. However, until that time, adaptation to local market needs fulfills the central position of marketing, which is value delivery to local needs.

MODELS OF STANDARDIZATION/ADAPTATION

Current models of standardization/adaptation recognize the importance of the firm’s operating environment through the employment of contingency models, that is, marketing strategy is a strategic response to competitive conditions founded upon the firm’s resources and its environment. Building on this conceptual foundation, researchers proffer the appropriateness of employing a strategy–environment coalignment theoretical perspective. Under this theoretical perspective, marketing strategy is viewed as a strategy–environment fit maximization exercise, where when a firm’s strategy is aligned with the firm’s internal and external factors, a firm performs at an optimal level, thus achieving above normal returns (*see* FORCES AFFECTING GLOBAL INTEGRATION AND GLOBAL MARKETING). This conceptual framework incorporates, at

a minimum, three key features critical to understanding the inherent marketing strategy–performance relationship, that is, (i) the unit of analysis underlying the framework is the individual venture, (ii) the framework posits that firm/brand performance involves multiple outcomes, and (iii) the framework is presented in general terms, thus allowing for flexibility in the internal and external variables included, thus allowing for industry-specific deviations in salient criteria.

First, in terms of the unit of analysis of the venture, researchers contend that it is centrally important to the scope of responsibility of marketing strategy. If the scope of responsibility is at the brand level, then brand-level criteria should be employed; if at the strategic business unit level then analysis should occur at that level. Only when the specified unit of the venture can be identified will effective understanding of marketing–strategy standardization/adaptation be observable. This issue is becoming increasingly problematic where primary data from a specific venture of the firm (e.g., brand) is captured and matched with firm-level performance data (when the firm has multiple brands). Although this approach works to overcome issues of common method bias, the violation of the scope of marketing–activity responsibility coupled with differences in units of measurement (a single brand’s marketing–strategy decisions paired with the firm’s performance – which included multiple brands) results in bias.

Second, the framework posits that multiple performance outcomes be considered. In the marketing–strategy literature, research continues to demonstrate differential performance results from a single antecedent element when performance metrics are varied. As such, decomposing performance metrics into aspects, such as financial, strategic, or behavioral, becomes important for clarifying the effects of marketing–strategy standardization/adaptation on firm performance (see MARKETING METRICS). For example, a firm may adapt its marketing strategy within a new market to serve local needs. By doing so, the long-term strategic goal of gaining market share could be achieved, while financial performance may denote lower margins (due to increased marketing costs associated with the adaptation).

Third, both internal and external factors are conceptualized to influence marketing–strategy standardization/adaptation (Cavusgil and Zou, 1994). Internal factors relate to the firm and encompass a wide variety of issues, inclusive of, but not limited to, management forces (such as international experience of management, number of languages spoken by key managers, specific country/regional interests of key managers) as well as firm-related factors (such as the firm’s involvement in international business activities, the transferability of the firm’s current offering, financial position of the firm, the firm’s access to capital in new markets). External factors relate to the operating environment of the firm encompassing both competitive and market characteristics. For example, issues such as the competitive intensity in the market, legal requirements for market entry, level of consumer demand, level of consumer sophistication, and so on, are all considerations determining marketing–strategy standardization/adaptation.

CONCLUSION

The issue of the standardization/adaptation of marketing strategy has made great progress; however, much is yet to be done. While the field has identified the research question, it is yet to come to a consensus on the conceptual domains of the central elements. The field will struggle with this issue as it moves forward. The four issues discussed here are less points of argument than points of clarification, wherein, when addressed, clearly identifiable solutions are evident. The four issues, when taken into consideration, provide a clearly focused research avenue under a contingent–model approach for the investigation of the standardization/adaptation of marketing strategy.

international product innovation and development

Roger J. Calantone and Janell D. Townsend

For millennia, individuals and firms have tried to create local or regional monopolies through differentiation. By offering a good, product, or service that was better in some (generally tangible) manner the aspiring monopolist could command a price differential from the price paid for the ordinary good purchased by the “mass” market. When unobservable quality or exclusivity was the differentiator, special “trademarks” denoted the distinctive outputs of the maker. As countries industrialized various economic sectors in the 1800’s efficiency allowed prices to fall dramatically and mass production with little differentiation began to dominate the scene. In the 1830’s clockmakers in Connecticut were able to produce clocks so cheaply that almost every working household had the means to purchase a mantle place clock, whereas in Europe at that time, clocks were still made individually – only the wealthy had clocks. Skilled workers in industries such as this, possessing both the explicit and tacit learning of their employer’s processes, immigrated to new countries where they became agents of innovation in processes that increased productivity. The most common base differentiator was price accomplished through cost economies of process reengineering allowing for the mass diffusion of innovation across markets. Such engineering of efficiency reduced waste, which coincidentally has beneficial effects on quality delivered. No one country was a single source of this systematic industrialization, although resource endowments allowed some to move process innovation forward more rapidly. Thus, process innovation delivered production economies to mass markets, and in today’s global marketplace, differentiation is derived from product innovation itself.

This article reviews international product innovation taking an activist firm perspective with respect to global product development. First, an overview of the nature of strategic innovation management in global markets is presented. The strategic intent and role of standardization versus adaptation in global products

is then discussed. Next follows a delineation of significant factors associated with organizing and managing global product innovation, and a conclusion summarizes.

STRATEGIC INNOVATION FOR GLOBAL MARKETS

In today’s global marketplace, the process of innovation relies heavily on flexibility, speed, and efficiency as the rates of technological innovation have increasingly shortened product life cycles, and enabled a broader and more diverse set of competitors. During this period of increasing resource constraints as well as greater competitive threats, companies are faced with the need to accelerate product development (Rothwell, 1994). The growing complexity and pace of industrial technological change are forcing firms to first understand the role and importance of global product innovation, how this fits with the firm’s level and strategic orientation toward globalization, and the interaction of these forces with the international marketing concept of the company.

New product development (NPD) involves the necessary but competing goals of minimizing risk by acquiring sufficient market information while reducing costs and time to market, thus escalating the importance of NPD process design and implementation (Harmancioglu *et al.*, 2007). In other words, a firm’s NPD processes and how they are implemented are vital for decreasing lead time and increasing innovation productivity. NPD processes involve a series of stages aimed at delivering a functional commercial benefit to customers (Calantone and DiBenedetto, 1995). Proficiency in executing NPD processes is important because it determines the degree to which businesses can meet and/or exceed customer demands, and thus succeed in a global marketplace (Cooper, 1991). The stages of NPD are rather universal, although various authors break it into as few as three steps and as many as forty, according to a particular application. There is no “one size fits all” approach to NPD, so the organizational design elements of each firm are different and come into play at different stages of the NPD process. However, each element plays a

2 international product innovation and development

vital role, requiring careful consideration and planning.

GLOBAL ORIENTATION OF INNOVATION

Globalization of the firm has been conceptualized as the transformation of businesses from domestic, to multinational, to those with global scale and scope (Ghoshal, 1987; Perlmutter, 1969). Following the basic tenets of incremental internationalization applied to the globalization process (Johanson and Vahlne, 1977), increasing knowledge of global markets yields a hierarchical structure of potential structural orientations. This is based on complex interactions with respect to the role of market attractiveness, experiential learning, and mimetic behavior in globalization patterns (Townsend, Yeniyurt, and Talay, 2009). The level of commitment is not static over time, but dynamically ranges from initial market entry approaches such as casual exporting to very high levels of integration for the more globally oriented firms. Identifying the current firm orientation toward internationalization provides a basis for understanding the underlying philosophy that guides the organization's approach toward international strategy and decision-making (Cateora and Graham, 2009). Global orientation is conceptualized as the organization's ability to view the entire world as its marketplace, not relying on individual markets or regions exclusively, or independently. While a multidomestic company treats customers and competitors in each country or region on a stand-alone basis, a global company takes an integrated approach across countries and regions (Birkinshaw, Morrison, and Hulland, 1995; Zou and Cavusgil, 2002). This means emphasizing the global success of the firm, as opposed to accentuating nation- or market-based measures (Ohmae, 1989), and is consistent with Perlmutter's (1969) original conceptualization of the geocentric firm. Yet, the implementation of a global orientation remains a major challenge for leadership, when trying to integrate a global strategy and a global structure (Roth, Schweiger, and Morrison, 1991; Yip, 1992; Zou and Cavusgil, 2002). High-level strategic orientations such as these impact all elements of the marketing mix, with innovation and product

development being among the core processes undertaken by the firm (Townsend *et al.*, 2004).

Three general international marketing concepts are commonly used to define level of commitment: domestic market extension concept, multidomestic market concept, and global marketing concept (Cateora and Graham, 2009). The domestic market extension concept is characterized by the selling of domestic product in foreign markets. Minimal to no adaptation is done to the marketing mix. The multidomestic market concept is characterized by a firm's recognition of the importance of the differences in foreign markets along with the recognition of the importance of international business to its operations. Companies that operate under this approach tend to look at foreign markets as being vastly different, and accordingly, requiring a unique strategy for each country. At the core of the global marketing concept are the efficiencies that can be obtained through standardization. In general, strategy is set at a global level with the understanding that some decisions are affected by local influences and will need to be looked at on a country-by-country, or region-by-region basis. From this conceptual perspective, the entire world is seen as a market, with segments that span multiple countries.

PRODUCT POLICY: STANDARDIZATION VERSUS ADAPTATION

The globalization of product marketing originates from the debate about the relative level of marketing mix standardization (Buzzell, 1968). It appears that consumer expectations around the world are beginning to converge in terms of needs and expectations as products that deliver a consistent identity have become more viable. A study identifying "marketing universals" found that there are few differences in consumers' use of quality signals across cultures—yet, only for selected levels of segmentation (Dawar and Parker, 1994). Research does suggest a general degree of homogeneity across market segments which transcend national boundaries (Yavas, Verhage, and Green, 1992). This is supported by recent findings that socioeconomic variables moderate the effects of cultural dimensions on the acceptance of new products (Yeniyurt and

Townsend, 2003), and the degree of foreignness of new products is having less of an effect on performance over time (Townsend, Calantone, and Schmidt, 2003). Thus, product policy related to standardization versus adaptation is the function of the firm's strategic orientation coupled with the degree of homogeneity across geographic and cultural markets.

A firm's international product policy is critical due to cost ramifications, and the inimical prospect that value creation and transmittal manifests in the product. Packaging style, quality, labeling, and brand name may seem trivial to some. Yet, these characteristics play a major part in international marketing due to the degree of calibration with cultural norms and preferences. Some products may need to be slightly altered and others not at all. Observations from the marketplace seem to support the idea of finding an appropriate balance between standardization and adaptation (Cavusgil, Zou, and Naidu, 1993; Jain, 1989b), with the premise being to embrace the concept of being global, but acting locally as necessary.

Standardization. A standardized product policy generally means that the firm will create a standard product to be sold in all markets served. However, companies will sometimes market their current domestic product internationally, as is, under the same brand name, in the same packaging, and with the same level of quality. The product policy does not change irrespective of the target market. While this approach preserves the low cost producer idea, long production runs, undifferentiated marketing, and economies of scale and experience, driving per unit variable and fixed costs downward, it ignores an inherent need for variety within any culture, and the differences of tastes between cultures. This is hubris in the face of the diversity of other cultures, and usually market punishment is quick and sure.

The primary benefits of a standardization approach to product development are the production economies and other cost savings that can be obtained. Supporters of standardization believe that price, quality, and reliability will offset any differential advantage that having a culturally adapted product would provide in

the eyes of the customer (Jain, 1989b). A standardized product policy can be useful because economies of scale are created in activities, especially in research, development, manufacture, and marketing (Kuvykaite, 2008). Some market segments are the same no matter where they exist geographically (Katz, 1987). Proponents of standardization argue that with the increased levels of global communication and other worldwide socializing, the tastes, needs, and values in a significant sector of the population across all cultures has become more homogeneous. The argument is that market segmentation is based on the lifestyle of the consumer, and standardized products can be marketed globally when the segmentation scheme is done using criteria other than geography alone. Product standardization is a forerunner of overall marketing mix standardization, reducing the complexity of operations. Standardization allows for less complex organizations that are easier to manage and control (Majaro, 1982).

No policy is without disadvantages though. Marketing flexibility is lost because of the inability to match the product to local requirements. Standardization suppresses entrepreneurship because a standard global product is accepted in all markets, complacency sets in and fresh new ideas are few and far between (Wind, 1986) – some personnel may be lost to organizations that provide more opportunities for creativity in marketing and product design (Majaro, 1982). Also, standardized products can be too complicated for some markets and too simple for other markets; some markets may need extensive training before accepting a product, while others may find the product too simple and will thus reject it (Wind, 1986).

Industrial customers around the world are generally more similar than their consumer goods counterparts because their purchasing decisions are driven less by attitudes and feelings, and more by economic considerations. Because of this, standardization is typically seen as the strategy of choice for manufacturers of industrial products. The main concerns of industrial customers are service, dependability, quality, performance, and cost (Cateora and Graham, 2009). Also, in recent years, there has been a trend toward more international standards (e.g., ISO standards) (Usunier, 2003), providing

impetus for using a standardization strategy for industrial products.

Adaptation. Adapting products for international markets simply means expanding the organization's product line (Calantone, Cavusgil, and Schmidt, 2004). Supporters of adaptation say it is inevitable. The most important objective of a firm is not minimization of costs through standardization, but long-term profitability, achieved by satisfying various consumer needs in different countries, thus ensuring greater sales (Pimblett, 1997). Many of the benefits of an adaptive product policy are obvious. For instance, the more a product is tailor-made for a specific market, the better it will fit the needs of the customers (Calantone, Cavusgil, and Schmidt, 2004). This, in turn, should lead to higher sales and sustained growth. A product adapted to a target market based on market research is more likely to succeed, and therefore carries less inherent risk than a standardized product.

Drawbacks to the adaptation approach can include increased costs related to research and development and the loss of scale economies. There may also be an increase in the complexity of the organization in response to the addition of foreign market operations to the preexisting domestic market operations. This will add a level of complexity to the management and an overall control of the organization. When defining the level of international commitment, management should ensure that they have the appropriate level of resources committed to the foreign endeavors (Cateora and Graham, 2009). From a consumer's standpoint, multiple products with different packaging and different brand images can cause identity or credibility problems.

Adaptations can be grouped into two categories: obligatory adaptation and discretionary adaptation. Obligatory adaptations are defined as those that an exporter is forced to undertake because of regulations that must be met in order to enter a foreign market or because of external environmental factors (e.g., climate considerations). Discretionary adaptations are voluntary adaptations that a firm undertakes in order to better align its product with market needs or other cultural factors (Jain, 1989a).

Several considerations come into play when determining the level of adaptation necessary for a product in a foreign market. In order to understand all the possible ways a product can be adapted it should be deconstructed into components based on benefits delivered. Major adjustments to the core component can be costly if changes to the production processes must be made to accommodate the specialized products. This may require a large capital investment. Auxiliary components include things such as packaging which protect the product's integrity, but also serve as a communications platform, sometimes tightly regulated by governmental edits.

The importance of the features contained within the packaging component depends on the need that the product is designed to serve. For example, in countries where literacy levels are relatively low, packaging must include symbols or pictures to aid the consumer in identifying the contents of the package and the appropriate usage. In other instances there may be legal requirements for labeling (e.g., information printed in multiple languages). It could also be the case that package sizes are regulated by law. External environment factors, such as humidity, could also bring about the need for adjustments to packaging. In some countries, such as Japan, the quality of the packaging has a direct impact on the consumer's perception of the quality of the product within.

In addition to the physical and service aspects of product adaptation, the impact of the symbolic attributes related to a product must also be examined (Usunier, 2003). In order to determine the symbolic attributes a product may have, a firm needs to first understand the culture of the country in which the product will be sold, including elements such as materialism, social institutions, belief systems, and language. There are two types of cultural knowledge that are necessary: factual and interpretive. Factual knowledge can be easily learned; interpretive knowledge, conversely, requires cultural insight usually acquired through personal experience.

ORGANIZATIONAL DESIGN

Organizational design elements are critical to success if product innovation and management

is to be successful across global markets. Global organizations need to determine and achieve a balance between central authority and responsiveness to local preferences that optimizes their business position (Johansson and Yip, 1994; Roth, Schweiger, and Morrison, 1991). Influential organizational design elements include formally planned stages, senior level involvement, business case preparation, customer input, and cross-functional integration (Barczak and McDonough, 2003), while a business case delineates project goals, market projections, and possible product specifications (Harmancioglu *et al.*, 2007). Coordination mechanisms in NDP include linking electronically geographically dispersed parts of the organization via intranets, extranets, and so on (Boudreau *et al.*, 1998), best practice repositories, and lead centers of excellence (Frost, Birkinshaw, and Ensign, 2002).

Subsidiary integration and global product mandates. A general trend has been observed such that multinational corporations have begun initiatives focused on integrating value-added activities which were once globally dispersed. This global dispersion occurred as a response to host government import/export regulations and tariffs, but with the globalization of business in recent years, these types of dispersed organizational structures are no longer necessary. Utilizing formal and informal interfunctional coordination mechanisms allows organizations to achieve global responsiveness while balancing flexibility and efficiency (e.g., Bartlett and Ghoshal, 1987; Martinez and Jarillo, 1991). With increased globalization foreign subsidiaries are now being used in more specialized roles with greater market scope (e.g., exporting) but narrow functional and/or product responsibility (Birkinshaw, 2002). World product mandate gives global responsibility to a subsidiary for development, manufacturing, and marketing of a single product line. Although full-scope mandates of this nature are relatively rare, regardless of scope, the primary outcome of the mandate process is greater specialization in terms of focused product responsibility (Birkinshaw, 2002).

In terms of specialization there are two theoretical approaches: rationalization-integration

and world product mandate. Rationalization-integration occurs when a subsidiary produces a component under assignment from the parent organization for the firm as a whole. Exporting is controlled by the subsidiary but upstream responsibilities such as development and design are controlled by the parent organization. Full-scope world product mandate, as mentioned previously, gives full control of development, manufacturing, and export marketing to the subsidiary. In this type of relationship, the subsidiary acts more as a partner than a subordinate to the parent and has a higher level of autonomy than in the rationalization-integration approach (Birkinshaw, 1996). In practice, a hybrid approach is more commonly observed; for example, a subsidiary may have global production and marketing responsibilities but utilizes central R&D resources for new product development.

There are four motives that are generally accepted classifications of subsidiary mandates: market-seeking, resource-seeking, efficiency-seeking, strategic asset-seeking (Birkinshaw, 1996). Each has a set of characteristics related to the business benefit the parent organization is attempting to achieve via the mandate. There are several challenges related to the establishment and management of subsidiary mandates. One such challenge is the restructuring of the organization to accommodate a new decentralized decision-making and reporting structure. The estimated value addition from the subsidiary should be able to cover the costs associated with this restructuring. Also, typically, the products assigned as a part of the subsidiary mandate approach are usually products at the end of the product life cycle. Care must be taken to ensure that the subsidiaries remain relevant to the current strategic vision of the parent organization even if the primary focus is on a product that is not at the forefront for management. Lastly, because of the specialized nature of these mandates, foreign subsidiaries are vulnerable to changes in the marketplace. If subsidiaries are unable to adapt to the market changes, or if organizations are unprepared to shift mandates to different subsidiaries to meet market needs, the mandate approach will be unsuccessful (Birkinshaw, 1996).

Open innovation. Traditionally, the ideas and concepts that feed innovation have been generated via experts and/or scientists within internal research and development departments. Recently, more organizations have adopted an approach which includes “open innovation” in the new product development cycle. Open innovation utilizes ideas and inspiration from “creative consumers.” These creative consumers differ from mainstream consumers in that they are excited by new ideas whereas mainstream consumers tend to like what they already know. The open innovation theory proposes that tapping into these creative consumers will help to overcome the thinking that most market research is backward looking as opposed to the forward-looking approach that is needed for product innovation (Clegg, 2008).

The engaged consumer has always existed, but now they are easier to identify and access via social networking and user-generated communities. The openness emerging from user-generated forums is where the true gain accrues relative to the classic opinion/idea collection methods of surveys and focus groups. The use of the web as a means of communication gives companies access to consumers on a global scale which is more difficult and expensive using the classic methods of data collection. This broad and global perspective on consumer ideas gives companies an advantage when attempting to generate breakthrough innovations.

Although disruptive product innovation appears to be key to the long-term health of an organization, there is no assurance that the ideas generated from open innovation mechanisms ultimately lead to these highly coveted product outcomes. The volume of information acquired can itself hinder the creative process. Automated tools provide an information capture mechanism, but the screening and sifting task to discover something commercially successful can be frustrated in many ways. This uncertainty drives many firms to opt for incremental product line extensions that utilize their current business capabilities as opposed to the more risky breakthrough innovation route.

Cooperation in the new product development process. The complexities of the global

marketplace have required companies to forge new vertical and horizontal alliances and to seek greater flexibility and efficiency in responding to market changes. These multifaceted and complex organizational relationships seek to establish or extend a firm’s differentiation by way of an alliance, either vertically in its value chain or horizontally through either competitors or complementary companies. Since alliances allow for the pooling of resources, it stands to reason that they would create a broader range of resource opportunities in the product innovation process. Through alignment and extension, collaboration with a partner provides an opportunity to fulfill the requirements of a sustained competitive advantage, which cannot be achieved independently; through the efficient use of a partner’s existing resources, the boundaries of the firm can be effectively extended. This includes knowledge sets that are both externally facing like culture and markets, and those that are internally oriented like product-specific processes.

In recent years, the trend has been for organizations to cooperate with different external partners as a way to enhance the efficiency and effectiveness of the new product development process, cut costs, and to reduce risk. These partners can include distributors, consumers, universities and research centers, and even competitors. Studies suggest that there is a positive relationship between cooperation and the achievement of success in the process of innovation. Cooperative alliances can be divided into two categories: (1) those based on synergies and complementary assets; (2) those based on growth opportunities and market power (Arranze and Arroyabe, 2008). Cooperation can be further identified as “vertical” or “horizontal” cooperation, respectively. Vertical cooperation (also known as supply chain cooperation) plays an important role in the collection of information on technologies, user needs, and markets. Partnerships with suppliers are seen as a complement to internal R&D activities as opposed to a substitute for them, and partnering with customers reduces the risks associated with market introduction. With horizontal cooperation, competitors may have complementary resources which will allow both parties to reduce costs and risks in large projects.

These types of partnerships are best suited for scenarios where either a strong common interest has been identified, for example, cooperating on the development of a new range of product or services, or scenarios where the resulting research leads to generic results (Arranze and Arroyabe, 2008).

There are a number of benefits derived from using a cooperative approach to new product development (Vilaseca-Requena, Torrent-Sellens, and Jimenez-Zarco, 2007) – for example, the establishment of work teams made up of experts in different functional fields who adopt flat structures (e.g., minimal layers between employees and management) that are highly adaptable, wherein decisions are taken in a decentralized way. Cooperation also favors the creation of products designed for and adapted to new needs and demands, and the development of a more efficient process of innovation that incorporates the “voice of the consumer” together with the experience and know-how of other partners. It also reduces the uncertainty surrounding the product’s future and its dependence at the time of product launch, while improving on the results obtained.

Yet, it has been estimated that approximately 60% of established cooperative relationships fail, and there are various factors that have been identified as barriers to effective cooperation. Lack of familiarity between the partners, the distance that separates them, and the absence of prior collaboration experience are noted as the most important inhibitors of the process of cooperation. The issue of lack of familiarity arises when the primary organization fails to research what each partner’s desired benefits, level of risk aversion, level of commitment, and strategic similarity are prior to the beginning of the project. The issue of distance can be physical, time related, or cultural. The last inhibitor, the absence of prior collaboration experience, arises when partners have not been a part of these types of alliance previously. The thought is that partners with prior experience will be more able to efficiently and effectively partner with organizations in new alliances making the overall management of the relationship easier for all parties (Vilaseca-Requena, Torrent-Sellens, and Jimenez-Zarco, 2007).

Partner selection and management is inherently important. Prior to beginning a project, each party should agree to the specific benefits to be gained from the relationship, as well as the risks and compromises they are willing to accept. When selecting partners to join these types of alliances, special consideration should be given to whether the partner has the necessary resources/capacity to meet agreed commitments, whether the partners’ culture or strategy is compatible with the primary organization, and whether the help of the partner can increase the efficiency and efficacy of the innovation process (Vilaseca-Requena, Torrent-Sellens, and Jimenez-Zarco, 2007).

Product platforms. Expanding internationally can be a difficult and costly task. To circumvent some of the costs and problems associated with this, many firms use product platforms. Broadly defined, a *platform is a set of product components that are physically connected as a stable subassembly and are common to different final models* (Muffatto, 1999). In other words, it is a foundation that can be used to create several different final products. The automobile industry uses product platforms for several components that are used in a variety of their models. The product platform concept represents a powerful approach for manufacturers to compete cost-effectively in a global market that requires diverse product range, quick time to market, and rapid responses to supply sources (Zhang, 2008).

There are many benefits to using product platforms. It creates flexibility by allowing companies to produce multiple product variations with limited impact on production and assembly processes. It also reduces the need for a large number of parts, which in turn reduces the amount of suppliers needed, and reduces costs. Another key benefit derived from the use of product platforms is a reduction in lead-time, and the reduction or elimination of many preassembly operations that reduces the throughput time. This helps companies react to market changes faster.

The biggest challenge in using product platforms is how to strike a balance between commonality and modularity. In other words, how common can a product line be while still creating enough variations to satisfy the global

market? The concept of platforming enables the manufacturer to further “commonize” the product family into fewer variants in order to take advantage of economies of scale (Zhang, 2008). However, platform approaches often result in the reduction of the range of customer choices, which can hinder overall sales.

Global product development teams. There is further complexity involved when broad geographical considerations are added to the innovation management and NPD equation. Global new product development teams are often established to address the needs of common global markets, to incorporate the unique needs of local markets, and to bring together globally diverse resources and expertise (Barczak and McDonough, 2003). Yet, these teams are often difficult to manage because of geographic and cultural diversity; these groups can achieve a higher level of performance if there is a significant degree of information exchange (Cummings, 2004). There can also be conflict between functional group members such as engineering and marketing (Maltz and Kohli, 2000), which impedes the effective development and ultimate success of new products – this effect can be exacerbated in culturally diverse groups. Thus, it is argued that the way work centers are structured and their relationship to the international network should be based on the underlying characteristics of a firm’s knowledge-based assets (Birkinshaw, 2002) and the global strategic orientation of the firm.

CONCLUSION

Managing global product innovation and development presents quandaries for international companies with respect to balancing the need for within-country representation with between-country comparability. As efficient production processes themselves became commonplace, product differentiation emerged as a key in creating a sustainable competitive advantage. This article reviews some of the more salient issues faced by managers of product innovation and development in a global marketplace. Global strategic orientation of

the firm plays a key role in determining the nature of product development, interacting with the degree of global market segmentation for the industry to determine the relative level of product standardization or adaption to be supported. This is a key point because of the costs and benefits that can accrue to the firm through innovation. Organizational design structures and elements support the NDP processes, and are particularly complex for global products and variations. As the world continues to become more integrated through technological advancement, governmental initiatives, and infrastructure improvements, global product innovation and development will evolve to meet the challenges of the marketplace.

managing the global product portfolio

Warren J. Keegan and Elyse Arnow Brill

INTRODUCTION

Managing the global product portfolio has been a topic of discussion and debate in the marketing literature for the past five decades. Commencing with global advertising (*see* INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?) in the early 1960s, the entire MARKETING MIX has been included in the standardization versus adaptation debate. There is, however, among proponents of either approach, the fundamental recognition that the discipline of marketing is universal, that is, it is a set of concepts, tools, theories, and practices that together constitute a body of knowledge that can be applied to varying competitive markets (*see* COMPETITIVE ANALYSIS) around the world.

THE STRATEGIC CONCEPT OF MARKETING

While the marketing discipline is universal and global, markets are differentiated. Market conditions vary from world region to region, from country to country, and from segment to segment within countries. Marketing objectives and target-market scope may be directed to local, national, regional, or global areas. Indeed, there are today BORN GLOBAL firms that have never had a primary, domestic market (Knight and Cavusgil, 2004).

What makes this debate possible is the evolution of the marketing concept from one focused on the sale of a “better” product defined by standards and values determined by the company, to a strategic concept of marketing that has shifted the focus from the product and its interaction with the consumer to everything. The global marketer must know the customer in a context defined by existing and future competition (*see* COMPETITIVE ADVANTAGE: ITS SOURCES AND THE SEARCH FOR VALUE), regulation, government policy, and the influences of economic, technical, social (*see* SOCIAL CLASS; CHILDHOOD SOCIALIZATION AND INTERGENERATIONAL INFLUENCES; SOCIAL INFLUENCE; SOCIAL

NETWORKS), cultural (*see* SUBCULTURES; CROSS-CULTURAL PSYCHOLOGY OF CONSUMER BEHAVIOR; MARKETING ASPECTS OF CULTURAL DISTANCE; BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS), and political macro forces that shape markets and their evolution. Everything matters. In the global auto industry, for example, successful competitors must meet world standards of functionality and performance, as well as world class appeal of design, fit, and finish that appeal to customer emotions. This means that the successful global competitor must have designers, stylists, and engineers who communicate with each other and who are aware of market demands in every world region that the company addresses in its global marketing effort. The successful competitor must also be price competitive (*see* PRICING STRATEGY; INTERNATIONAL PRICING OBJECTIVES AND STRATEGIES), and this requires the elimination of unnecessary differentiation and duplication of effort.

INTEGRATED GLOBAL MARKETING

An important issue in global strategic marketing is whether theory and experience based in national markets is applicable to global marketing (Hongsik, Change-Hoan, and Sutherland, 2007). Discussion has focused on the benefits and/or drawbacks of standardization (*see* BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS), arguments for or against a growing homogeneity of markets and customer needs, contextual factors having an impact on the degree of MARKETING MIX, standardization, and performance outcomes of the standardization and adaptation approaches (Birnik and Bowman, 2007).

Howard Perlmutter identified three managerial orientations in his seminal 1969 article, *The Tortuous Evolution of the Multinational Corporation* (Perlmutter, 1969). These orientations included an ethnocentric or home-country orientation, a polycentric or host-country orientation, and a geocentric or world orientation. Almost twenty years later, Bartlett and Ghoshal's (Bartlett and Ghoshal, 1989) typology of organizational development (domestic, international, multinational, and

2 managing the global product portfolio

global) reflect different orientations and strategies of globalizing companies. With reference to the marketing function, Sheth, in 2001, and others before him, postulated that in light of important macroeconomic forces shaping the world and its markets, a “borderless world” was emerging where national boundaries were becoming less relevant to marketing and marketing planning practices (Sheth, 2001a). Sheth suggested that *intranational* differences were overtaking *international* differences; for the global marketer, *within-country* differences were displacing *between-country* differences in importance. Accordingly, he suggested strategic marketers consider different target markets within a country, similar to those that might exist on a global basis.

By focusing in this manner, a company’s perspective shifts from between-country differences to transnational similarities across national boundaries. In Sheth’s words, “the elitism of the diffusion in innovations from the home country to the rest of the world [is] replaced with the concept of worldwide markets” (see DIFFUSION OF INNOVATION); (Sheth, 2001b). MARKETING PLANNING would provide target-market coverage on a worldwide basis (Sheth, 2001c).

A second shift at the organizational level supports this focus on transnational similarities with the goal of creating value (see CUSTOMER SOLUTIONS; A FRAMEWORK FOR CREATING VALUE PROPOSITIONS) for targeted customers. This dual geocentric view at the organizational and customer levels demands, among other things, continued efforts to lower costs and increase learning and knowledge sharing across the global enterprise.

THE STANDARDIZATION/ADAPTATION DEBATE

Buzzell offered one of the first theoretical discussions of standardization as an international marketing strategy in 1968 (Buzzell, 1968). He argued that dissimilarities among countries led multinational firms to perceive and design MARKETING PLANNING in each country as a local problem with localized solutions. Buzzell provided several rationales for an international standardization strategy

(see STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY), most importantly, cost savings arising from standardization of the MARKETING MIX elements and the creation of a single marketing strategy spanning the globe. He applied standardization strategy to the marketing mix elements – the 4 Ps of product, pricing, promotion, and place, highlighting potential economies in PRODUCT DESIGN decisions, (see GLOBAL PRODUCT DEVELOPMENT), advertising (see INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?), packaging and messaging (see INTEGRATED MARKETING COMMUNICATION STRATEGY) relating to brand development (see BRAND GROWTH STRATEGY; BRAND STRATEGY; BRAND VALUE) as well as organizational/operational elements including stronger planning, control, and the use of ideas with transnational appeal in as many markets as possible.

Among the many obstacles to standardization, Buzzell noted important market characteristics including a target market’s stage of economic and industrial development, the myriad of existing attitudinal (see ATTITUDES) and cultural impediments (see CROSS-CULTURAL PSYCHOLOGY OF CONSUMER BEHAVIOR; SUBCULTURES) as well as product-use conditions and differences in marketing infrastructure (see MARKET/INDUSTRY STRUCTURE) including channels of distribution (see MARKETING CHANNEL STRATEGY; DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES) and media (see INTEGRATED MARKETING COMMUNICATION STRATEGY). Buzzell concluded that the pros and cons of standardization should be considered when designing and implementing a global marketing strategy. Decisions to standardize, he recommended, should be based on the net impact of standardization on estimated overall revenue and projected costs. “Obviously, each case must be considered on its own merits. . . .” (Buzzell, 1968).

Buzzell’s original question with respect to global strategy continues to ring true today. “Is it practical to consider the development of a marketing strategy in terms of all of its

elements on an integrated, global marketing scale?” (Buzzell, 1968).

As noted just over 30 years later, “customization” and “fine-tuning” of international marketing are included in the concept of global marketing (Sheth and Parvatiyar, 2001). Its underlying philosophy is standardization of marketing programs wherever possible and customization wherever necessary (Sheth and Parvatiyar, 2001). Keegan, in an article titled *Multinational Product Planning: Strategic Alternatives* published in 1969, identified four strategic alternatives using the marketing mix based on product-standardization versus adaptation and promotion-standardization versus adaptation dimensions (Keegan 1969). He concluded that the “choice of communications strategy . . . is a function of three key factors: 1. the product itself defined in terms of the function or need it serves, 2. the market defined in terms of the conditions under which the product is used . . . and, 3. the costs of adaptation and manufacture.” (see PRODUCT DESIGN; MARKET DEFINITION) Much literature in the field of international marketing has built on this multidimensional perspective (Quelch and Hoff, 1986) and continues to look beyond single strategy dimensions.

Theodore Levitt’s seminal 1983 article, “The Globalization of Markets,” has often been characterized as arguing that in the face of diminishing cultural (see MARKETING ASPECTS OF CULTURAL DISTANCE; BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS) and social differences (see SOCIAL CLASS; SOCIAL INFLUENCE) across countries, a standardized marketing strategy will increase profitability and competitiveness (Levitt, 1983). Levitt did assume that demand was becoming more homogenous worldwide; global consumers (see SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE; GLOBAL CONSUMERISM AND CONSUMPTION), he pointed out, were increasingly demanding high-quality, low-cost products and services. Driving this trend, he argued, were global communications, travel, and the emergence of a global consumer with shared experience, knowledge, and expectations. Although Levitt forcefully argued for the recognition of this

trend, he did not ever call for standardization per se. Like Buzzell and Keegan, he recognized that marketers should standardize where they could, and adapt where it was needed. He noted, for example,

Large companies operating in a single nation or even a single city don’t standardize everything they make, sell or do, [t]hey have product lines instead of a single product version, and multiple distribution channels. There are neighborhood, local, regional, ethnic, and institutional differences even within metropolitan areas. . . . Success in a world with homogenized demand requires a search for sales opportunities in similar segments across the globe . . . [T]he most effective world competitors incorporate superior quality and reliability into their cost structures They compete on the basis of appropriate value – the best combinations of price, quality, reliability, and delivery for products that are globally identical with respect to design, function and even fashion (Levitt, 1983) (see MARKET SEGMENTATION AND TARGETING; VALUE PROPOSITION; CUSTOMER SOLUTIONS).

Levitt acknowledged the creation of customer value (see CUSTOMER SOLUTIONS) as the basis of competition. Levitt’s point was not that standardization should be the uniform practice of global marketers. Instead, he underlined the importance of creating value (see VALUE PROPOSITION) by offering functional utility, quality, design, and price.

Proponents of a strategy of adaptation for globalizing firms highlight the obvious dissimilarities between and among markets of differing countries and regions and urge the global marketer to differentiate marketing programs. Such market diversity includes a full set of macro environmental factors including geographical, topographical and climate constraints, differing political and economic influences, and varying important cultural imperatives (see CROSS-CULTURAL PSYCHOLOGY OF CONSUMER BEHAVIOR) reflected in language, laws and regulation, and religious beliefs along with race and ethnicity considerations critical to successful marketing programs (Czinkota and Ronkainen, 1998). Proponents of this view urge that adjusting the determinants of the

4 managing the global product portfolio

MARKETING MIX and marketing strategy (*see* MARKETING STRATEGY IMPLEMENTATION) are imperative to comply with local custom, culture, and taste. Adapting market offerings to different markets, proponents argue, addresses the “friction” that necessarily exists between differing stakeholders because of environmental differences, thereby permitting better overall performance (Shoham, 2002).

The debate between the two “views” has been a tempest in a teapot. Levitt did not ignore the real differences within and between global markets. He identified the changes in globalizing markets that had created an opportunity to provide value (*see* VALUE PROPOSITION) to global customers (*see* SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE) by not only responding to differences but also by recognizing similarities and opportunities to reduce costs and increase quality through greater design unification. Success for globalizing international firms requires both adapting to unique differences and standardizing elements of the marketing mix that do not need to be adapted to meet customer needs. These marketing planning decisions highlight the trade-offs in each market between economies associated with standardization and the value added by differentiation (Viswanathan and Dickson, 2007).

THE NEW PARADIGM: MULTIDIMENSIONAL GLOBAL MARKETING STRATEGY

Successful globalizing firms have adopted a strategy of integrating standardization, adaptation (*see* STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY), and innovation in their marketing programs. For every component of marketing strategy and program planning, analysis is required to understand the optimal standardization/adaptation level. The recent development of both contingency and configurational theories have expanded the binary standardization/adaptation analysis and brought into focus the important contextual nature of global marketing strategy (Nanda, Viswanathan, and Dickson 2007).

Contingency theory posits that no universal set of strategic choices is most suited for all circumstances or organizations; strategic choices

are situation specific. Configurational theory holds that structural and program effectiveness arises from the superior combinations of strategic and structural elements, which, when combined in various ways, interact differently. These superior combinations have predictive capabilities for organizational behavior and success (Lim, Acito, and Rusetski, 2006).

Recent literature suggests variables influencing strategic marketing choices. Internal organizational elements include, for example, the degree of centralization of decision making and the international experience of the firm. Strategic variables highlight market entry modes (*see* MARKET ENTRY AND EXPANSION) and business goals and objectives. External elements include the size of the local market, degree of local competitive intensity and similarity of markets including their stage of economic development (*see* STAGES OF MARKET DEVELOPMENT), “psychic” or cultural distance (*see* MARKETING ASPECTS OF PSYCHIC DISTANCE; MARKETING ASPECTS OF CULTURAL DISTANCE) between markets, and similarity of legal and regulatory constraints and marketing infrastructure (Birnik and Bowman, 2007). Various classifications addressing multidimensional analysis have been highlighted over the years. In 2009, Nasir and Altinbasak proposed a conceptual framework encompassing many of these external and internal drivers (Nasir and Altinbasak, 2009).

The importance of identified contingency factors, whether internal or external, will vary with each MARKETING PLANNING decision. In light of this fact, differing elements of the MARKETING MIX reflect various levels of standardization, adaptation, or innovation. For example, there is evidence that the optimum level of standardization of the marketing process is higher than the standardization of marketing program content (Birnik and Bowman, 2007). Research into pricing patterns (*see* PRICING STRATEGY) shows this to be the least or one of the least standardized elements of the marketing mix with sales, distribution, and promotion not far behind. Studies indicate that packaging patterns reflect medium-to-high levels of standardization. Similar medium levels of standardization are applicable to advertising although research distinctions have been made

at the level of the basic advertising message, the creative message, and advertising content material as compared to preplanned design efforts.

The product is the element of the marketing mix with the highest potential for standardization. Industrial products typically offer more potential for standardization than consumer products because they are less influenced by local customs, taste, and habits. Major consumer durables offer greater potential for standardization because the components of the product are not visible to the consumer, and perform a function that is not influenced or affected by cultural differences. The automobile is a good example of a consumer durable with high standardization potential. All of the successful or would-be-successful global or globalizing automobile companies recognize this fundamental fact of their industry.

CONCLUSION

While the marketing discipline is universal, the heterogeneity of subnational, national, and regional markets does not allow complete standardization of international marketing planning or programming. It is necessary to adapt to certain differences in markets. On the other hand, similarities in markets can and, indeed, must be addressed with standardized elements of the marketing offering. The task of the global marketer is to adapt where adaption is needed and is worth the expense, and where it strengthens competitive advantage, and to standardize where it is not needed and adds unnecessary cost.

A multidimensional approach embraces important contextual, historical, and competitive factors found in diverse markets. Taking this approach, global marketing strategy plays an increasingly important role in determining both the strategic direction of a firm and its worldwide growth success or failure. The ultimate test of success is the creation of unique value where value is defined by the sweet spot where the benefits and price of the market offering afford the greatest value to the customer. Successful global companies have developed the ability to find that sweet spot, and have been rewarded by competitive success in global markets.

global branding: three keys for global brand success

Kevin Lane Keller

INTRODUCTION

Many companies have been global marketers for decades – firms like Nestlé, Shell, Bayer, and Toshiba have sold their products around the world for years. In more and more product categories, the ability to establish a global profile is becoming virtually a prerequisite for success. In luxury goods such as jewelry, watches, and handbags, where the addressable market is a relatively small percentage of the global market, a global profile is essential to grow profitably. Marketers for luxury brands such as Prada, Gucci, Cartier, and Louis Vuitton have long managed lucrative global franchises.

Besides the need for a larger customer base to achieve necessary economies of scale, companies may look to sell outside their domestic market for a number of different reasons: better perceived profit opportunities in international markets than in the domestic market; a need to diversify risk and reduce their dependence on any one market; a desire to counterattack global competitors in their home markets; and a realization that their customers are going abroad and require international service.

But global competition is intensifying as new firms make their mark on the international stage. The automotive market is becoming a worldwide free-for-all. In Chile, for example, because there are no domestic auto manufacturers, imports come from all over the world, including 14 different brands of Chinese cars, trucks, and commercial vehicles. Competition in developing markets has also intensified. In China's exploding mobile-phone market, Motorola found their market share drop in half over a two-year period because of inroads made by Nokia and different Asian competitors.

Competition arising from firms based in developing markets is also heating up (*see EMERGING MARKETS*). In various developing markets, India's Tata Motors have launched the people's car whose spartan features are offset by a rock-bottom price. Eyeing more developed markets down the road, Tata can

afford to charge a fraction of what other auto manufacturers charge because of their reduced development costs and innovative distribution strategy that requires dealers to participate in the final assembly.

India's Mahindra Motors are not even going to wait before entering developed markets. Their four-door, diesel-powered short-bed trucks are tackling the competitive small utility vehicle (SUV) and truck markets in Europe, Asia, and the United States with a promise of superior fuel economy. To offset a lack of image and reputation, Mahindra are targeting three groups in the United States that are believed to be most receptive to their appeals: consumers who identify themselves as "green"; people who have bought their other main automotive product, Mahindra tractors; and Indian expatriates.

Given the significant growth opportunities offered by international markets, developing a global strategy can be of paramount importance to brand builders everywhere. For many companies, however, global branding has been a mixed blessing. On the one hand, a global branding program can lower marketing costs, realize greater economies of scale in production, increase distribution efficiencies, and provide a long-term source of revenue. On the other hand, if not designed and implemented properly, a global branding program may fail as a result of ignoring important differences in consumer behavior and/or the competitive environment in the individual countries.

The goal for any brand builder, obviously, is to obtain as many of the benefits of global branding as possible while minimizing the potential risks and downside. Not surprisingly, many companies have experienced both tremendous success and embarrassing failures in their global branding efforts. It is not always the case that the most successful brand in one country will find success in other countries. Although US retail giant Wal-Mart have had some success entering the overseas markets in Latin America and China, despite concerted efforts, they found themselves having to withdraw from both the German and South Korean markets.

The goal of this article is to share some common themes or guidelines for success that have emerged in global branding (*see Johansson, 2009 for more detail*). We outline three keys

2 global branding: three keys for global brand success

for global brand success: (i) understand the global consumer context, (ii) build a solid global marketing foundation, and (iii) strike a balance in global brand management. They represent global branding fundamentals that provide the necessary foundation for creating a strong global brand. We raise a number of different issues and offer a number of different examples in each case.

UNDERSTAND THE GLOBAL CONSUMER CONTEXT

First – and perhaps most fundamental – it is important to recognize that international markets vary in terms of consumer behavior and all the different marketing forces and other factors that impact them (*see* BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS). As a result, consumers may vary accordingly in their perceptions, beliefs, attitudes, images, experiences, behaviors, and so on, toward both the brand itself as well as the product category in general. These differences can have profound implications on building and managing brand equity across geographical boundaries.

For example, consider the following (Hollis, 2008). The median age in India and China is roughly 25 years, whereas in Japan, Germany, and Italy it is around 43. When asked if they are more concerned with getting a specific brand than the best price, roughly two-thirds of Americans agreed as compared to around 80% in Russia and India. A lot of these differences in consumer behavior reflect cultural differences that can be pronounced across countries. Hofstede (1980) identifies four cultural dimensions that differentiate countries (with countries or areas that score high and low):

1. *Individualism versus collectivism*. In collectivist societies, the self-worth of an individual is rooted more in the social system than in individual achievement (high: Japan; low: United States).
2. *High versus low power distance*. High power distance cultures tend to be less egalitarian (high: Russia; low: Nordic).
3. *Masculine versus feminine*. This dimension measures how much the culture is dominated by assertive males versus

nurturing females (high: Japan; low: Nordic).

4. *Weak versus strong uncertainty avoidance*. Uncertainty avoidance indicates how risk averse people are (high: Greece; low: Jamaica).

At the same time, many countries do not vary much on one or more of these various considerations, suggesting that differences in marketing activity can create unnecessary or ineffective marketing activity. An important key to global marketing success is understanding consumers in different markets, recognizing what they know and feel, and could potentially value about the brand, and, as described below, tailoring marketing programs to their desires as a result.

Obviously, the fewer the differences in consumer behavior found across markets, the more effective a standardized marketing program will be. Some types of products travel better across borders than others. New products often represent promising candidates for standardization. While mature products may have vastly different histories (or even positions) in different markets, consumer knowledge for new products is generally the same everywhere because perceptions are yet to be formed. Many of the leading internet brands – Google, eBay, and Amazon – have made relatively quick progress in overseas markets. In addition, high-end products also benefit from standardization because a high quality or prestige image often can be marketed similarly across countries. On the other hand, food and beverage marketers find it more challenging to standardize their products as they have to contend with widely varying tastes and cultural habits and norms.

Developing markets. In understanding consumer behavior in a global context, because of the wide income and economic disparity involved, some of the biggest differences are found between consumers in developing or emerging (e.g., the BRICS countries: Brazil, Russia, India, China, and South Africa) versus developed markets (Mahajan, De Moraes, and Wind, 2000; Khanna and Palepu, 2006). These differences can have profound implications for how brands should be marketed (*see* EMERGING MARKETS).

For example, consider channels of distribution. Eighty percent of consumers in developing markets buy their products from tiny bodegas, stalls, kiosks, and mom-and-pop stores not much bigger than a closet, which Procter & Gamble call *high-frequency stores*. Smaller packaging and lower sales prices are often critical when incomes and housing spaces are limited. Unilever's 4-cent sachets of detergent and shampoo have been successful in rural India, where 70% of the country's population still lives. Coca-Cola's sales jumped when they moved to a smaller, 200-ml bottle in India, selling it for 10–12 cents in small shops, bus-stop stalls, and roadside eateries. Recognizing that their cost structure made it difficult to compete effectively in developing markets, Procter & Gamble have devised a number of cheaper, clever ways to make the right kinds of products to suit consumer demand there.

Fundamentally, marketers must rethink all aspects of their marketing program in developing markets. As another example, high cell-phone penetration in developing markets makes mobile marketing an attractive option. A pioneer in China, Coca-Cola China created a national campaign asking Beijing residents to send text messages guessing the high temperature in the city every day for just over a month, for a chance to win a one-year supply of Coke products. The campaign attracted more than four million messages over the course of 35 days. In Africa, mobile-phone operator Celtel invested in rural services by introducing the Me2U service, by which callers could send airtime credit to other mobile phones. Because most Africans do not have bank accounts, it has become a convenient and cheap way to transfer money, even substituting for cash in some villages.

BUILD A SOLID GLOBAL MARKETING FOUNDATION

The second guideline emphasizes the importance of building a solid global marketing foundation. A solid global marketing foundation results when (i) the proper marketing infrastructure is put into place; (ii) the right marketing partners are enlisted; and (iii) steps are not skipped in brand building.

Proper marketing infrastructure. A critical success factor for many brands has been their manufacturing, distribution, and logistical advantages in domestic and foreign markets (see DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES; GLOBAL SOURCING STRATEGY: AN EVOLUTION). This has involved (i) creating the appropriate marketing infrastructure “from scratch” (if necessary); as well as (ii) adapting to capitalize on the existing marketing infrastructure in other countries (Craig and Douglas, 2000).

Since international markets vary greatly in terms of existing infrastructure, companies have gone to great lengths to insure consistency in product quality. Through the years, Nestle have invested in systems, equipment, and so on, so that proper production and distribution infrastructure could be put into place that would otherwise not have existed. For example, Nestle devised “milk roads” in China to overcome local deficiencies in transportation and distribution systems.

More often, however, companies have to adapt operations and/or invest in foreign partners in order to succeed abroad. One of the most crucial global investments is the establishment of a reliable distribution system (Arnold, 2000). Companies often differ in their approach to distribution, and the results can be dramatic. For example, Coca-Cola's distribution strategy and ability to adapt to specific regional concerns (e.g., the necessity for vending machines in Japan) has been a key to their global success.

Sometimes, companies mistakenly adapt infrastructure strategies that were critical success factors, only to discover that these changes eroded the brand's competitive advantage. For example, Dell Computer initially abandoned their direct distribution strategy in Europe and instead decided to establish a traditional retailer network through existing channels, with poor results. Ignoring critics who claimed that a direct distribution model would never work in Europe, Dell revamped their direct approach and relaunched their personal computer line with a new management team to execute the direct model that the company had pioneered in the United States, finding greater success as a result.

4 global branding: three keys for global brand success

Developing a proper marketing infrastructure is especially important in developing markets. India still struggles with poor infrastructure and highly restrictive labor laws. Its retail channel structure, although improving, still lags. The quality of public services – education, health, provision of water – is also often lacking. In China, after a series of high-profile product quality scares and crises, government standards were put in place for product quality and safety standards in manufacturing to try to assure overseas consumers and gain their trust.

Right marketing partners. In developing their infrastructure, most global brands have marketing partners of some form in their international markets, ranging from joint venture partners, licensees or franchisees, distributors, ad agencies, and other marketing support personnel. One common reason for establishing brand partnerships is access to distribution. For example, Guinness have very strategically used partnerships to develop markets or provide expertise that the company lacked with their own personnel or capabilities. Partners can also help to make sure supply and distribution chains operate smoothly in different markets. With 226 offices in 70 countries, Seattle-based freight-forwarder Expeditors International help firms keep track of 3000 shipping containers and 2 million pounds of airfreight around the world.

Successful brand partnerships can become key components to overall profitability for each of the parent companies. The value of a partnership can extend far beyond increased sales or access to distribution. Good partners share “brand values” that help maintain brand consistency across markets. For example, McDonald’s fierce commitment to product and service standardization is one reason why the retail outlets are so similar all over the world. To achieve such consistency, McDonald’s handpick their global partners one by one in order to find “compulsive achievers” who will put forth the desired effort.

Avoiding branding shortcuts. Building a brand in a new international market needs to be done from the “bottom-up” – both strategically and tactically. Strategically, this means concentrating on building awareness first before building the brand image (i.e., to “lay the foundation” for the

brand). Tactically, or operationally, this means determining how to best create sources of brand equity in new markets. In other words, the means by which a brand was built in one market (e.g., the particular product, distribution, communication, or pricing strategies and marketing activities) may not be appropriate in another market even if the same overall brand image may be desired.

Many times marketing programs have to be adjusted because the brand is at an earlier stage of development in its new market (see MARKET ENTRY AND EXPANSION). In such situations, consumer education about the product itself may need to accompany brand development efforts. When Coca-Cola moved into developing markets in Asia, they encountered consumers who loved the brand, but had never drunk the product before. Not realizing it needed to be chilled, they required education as to the fact that it should be drunk cold.

The recommendation to avoid shortcuts suggests some patience on the part of marketers. Firms may have to “backtrack” to an earlier stage of brand development in these new markets and engage in a set of marketing programs and activities that the brand – in its existing markets – had long since moved beyond. Although the time taken to build the brand in new markets may be compressed because of greater financial resources and a keener understanding of effective strategies and tactics, it could still take some time. The temptation – and often mistake – is to export the current marketing program because it seems to basically “transfer” or “work.” Although that may be the case, the fact that a marketing program can meet with acceptance or even some success in a market does not mean that it is the proper marketing activity in terms of building a strong, sustainable brand equity there.

For example, when Nike made a big push into Europe in the early 1990s, they were too aggressive in their approach and overrelied on their well-known American sports stars. Although athletes such as Michael Jordan, Bo Jackson, and Wayne Gretzky were known to varying degrees in Europe, they represented sports (i.e., basketball, football, baseball, and hockey) that were not as popular in Europe as they were in America. As a result, the ads that were so captivating in

the United States generated much less fanfare in Europe. The brand met with some success, but failed to live up to its potential. Nike management soon came to realize that Nike's brand mantra of "authentic athletic performance" had a different meaning in the European culture. Instead of using American heroes playing American sports, Nike adopted a more "grassroots approach" to better reflect authentic athletic performance "European style." Soccer, or football, thus became an indispensable ingredient, and Nike sales began to rise accordingly.

Not taking shortcuts helps to create marketing momentum and support from a growing customer base in the new market. Red Bull deliberately adopted a phased roll-out program in entering a new market with imposed scarcity to help drive up interest and demand in their new functional energy drink product. Jamaica-based Digicel have successfully conquered many politically unstable third-world countries such as Papua New Guinea, Haiti, and Tonga by developing product and programs that appeal to the poor consumers who are typically otherwise overlooked. The fierce loyalty of these consumers helps to protect Digicel from any overly aggressive government actions or interventions.

STRIKE A BALANCE IN GLOBAL BRAND MANAGEMENT

Ideally, a single marketing program could be devised and implemented that would turn out to be the most effective and efficient possible option for each and every country in which the brand is to be sold. There are many advantages to launching such a globally consistent marketing program for a brand: economies of scale in production and distribution; lower marketing costs; power and scope; consistency in brand image; ability to leverage good ideas quickly and efficiently; and uniformity of marketing practices.

Unfortunately, such uniformly optimal global marketing programs are rarely possible. One implication of the similarities and differences across international markets is the need to blend local and global elements in marketing programs. The best examples of global brands retain a thematic consistency and alter specific

elements of the marketing mix in accordance with consumer behavior and the competitive situation in each country. An oft-heard – and sometimes modified – expression of prescriptive advice to marketers of global brands is to "Think Global, Act Local." In that spirit, HSBC are even explicitly positioned as "The World's Local Bank."

Perhaps the quintessential global brand, Coca-Cola, deliberately keep the basic look and packaging of their Coke brand the same everywhere (except in countries where laws dictate use of local language). Yet, the company simultaneously stress that the brand be *relevant* and well positioned *relative* to competition in different markets. They use different advertising agencies in different countries in order to make the brand feel local and be well positioned relative to local competition. For example, in Australia the advertising appeals to the same "classic, original" ideals but in a very Australian fashion. As a result, Coke becomes entwined with the cultural fabric of the country, just as it has in the United States. Over time, this yields an advantage with younger generations who do not even think of Coke as an imported brand. An illustrative example that Coca Cola recount is of a Japanese family visiting the United States for the first time: the young son, upon passing a vending machine, joyfully exclaimed to his parents, "Look, they have Coke here too!"

Most brands are adapted to some extent to reflect differences in consumer behavior, brand development, competitive forces, and the legal or political environment across markets (*see* STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY). Even global brands undergo some changes in product features, packaging, channels, pricing, or communications in different global markets. Some aspects of the marketing program tend to be adjusted less frequently or dramatically than others (e.g., brand elements such as brand names, logos, packaging, and signage) whereas others are adjusted more frequently or vary more dramatically across markets (e.g., advertising and other communications and especially distribution channels). Even something as simple as a brand name may involve various decisions in terms of the use of dual names, choices between phonetic or

6 global branding: three keys for global brand success

semantic translations, and so on (Zhang and Schmitt, 2001; Hong *et al.*, 2002).

Even in advertising, it is not uncommon to have the same creative theme globally, but to adapt the specific execution to appropriate local markets (*see* INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?). Apple Computer's "Mac vs. PC", which was voted the best US ad campaign of 2006 by *Adweek* magazine, features two actors bantering. One is hip-looking (Apple), and the other is nerdy-looking (PC). Apple dubbed the ads for Spain, France, Germany, and Italy, but chose to reshoot and rescript for the United Kingdom and Japan – two important markets with unique advertising and comedy cultures. The United Kingdom followed a similar formula but tweaked the jokes to reflect British humor; the Japanese ads avoided direct comparisons and were more subtle in tone. GE's "Ecomagination" ad campaign retains the same message globally, but substitutes different ad creative and executions in Asia and the Middle East to reflect the cultural interest there.

The challenge, of course, is to determine the nature of the balance in the marketing program – which elements to customize or adapt and which to standardize. This balance can depend on a host of factors, for example, the cultural flavor of the brand or unique characteristics of the market in question. Customization may imply adjusting some aspect of the marketing program and/or the desired brand image (e.g., by the creation or deletion of brand associations). In some cases, because of differences in consumer behavior or because of historical market factors, brand positions may fundamentally be different in different markets (Aaker and Joachimsthaler, 1999).

- Heineken beer is a high-end superpremium offering in the United States, but more middle-of-the-road in their Dutch home market.
- The domestic image of Honda automobiles in Japan, on the other hand, is richer and the brand is more strongly associated with speed, youth, and energy than in overseas markets such as the United States, where it is seen as a reliable, quality vehicle.

- The Toyota Camry is the quintessential middle class car in the United States, but is positioned at the high end in China, even though the cars in the two markets differ only in very cosmetic ways.

Even if the positioning does not vary for a brand, the specific products and services that are emphasized may still vary. IBM have a two track approach with their services business: in the United States, where clients often are economizing, they focus on helping with cost cutting; whereas in developing markets, where clients are seeking to modernize and catch up with other countries, they help customers with their technology infrastructure.

Not sufficiently adjusting marketing for a global brand in a new market can lead to negative consequences. Much of the success of Finland's Nokia in cell phones has been due to their intense focus on innovation, design, and engineering in producing a wide range of products that vary in quality, price, and so on. This range has allowed them to be successful in both developing and developed markets. Despite this global success, however, they found their market share slipping in the United States when they failed to customize their cell phones to the various wireless carriers. Improving their partnership with wireless carriers resulted in greater retail presence in showrooms and stores, a critical success factor in that market.

As another example, despite some financial success, Korea's LG decided to hire a number of top executives from Western firms to help transform themselves from what they saw as "an engineering powerhouse that excelled in manufacturing and selling in different parts of the world" to a "globally efficient, trend-setting organization." The new executives were charged with standardizing the hodgepodge of processes and systems that LG had developed in different markets in purchasing, the supply chain, marketing, and other areas. In particular, a single agency (London's Bartle, Bogle, and Hegarty) was given global responsibility in marketing to sell an increasing number of higher-end products.

Finally, another issue in adaptation is the country of origin (*see* "COUNTRY OF ORIGIN" AS BRAND ELEMENT). Country of origin can

clearly play a different role in positioning brands in foreign versus domestic markets. Domestically, country-of-origin associations may attempt to stir feelings of patriotism and cultural heritage, but in foreign markets, it may be a means to leverage existing perceptions and beliefs about the home country. Even a perception of globalness for a brand – by sending a quality signal, tapping into cultural myths, and reinforcing a sense of social responsibility – can improve brand evaluations (Holt *et al.*, 2004; Steenkamp *et al.*, 2003).

There are numerous examples of companies that leverage country-of-origin associations to help position their brands globally: “German engineering” for BMW and Mercedes, “Aussie good cheer” for Foster’s beer, and “French elegance” for Chanel, Dior, and Louis Vuitton. A Western image can be helpful in developing markets, as Coca-Cola discovered in China (Batra *et al.*, 2000). Part of their success against local cola brand Jianlibao was due to the brand’s symbolic values of modernity and affluence. But not all country images are positive, and country-of-origin effects can be tricky when complex multicountry component and assembly are involved, posing challenges to global marketers (Tse and Lee, 1993).

Balancing local and global control. A key theme with organizational structures, entry strategies, and coordination processes and mechanisms for global brands is the need to balance global and local control. Coca-Cola, for example, have distinguished between marketing activities that would appear to dilute brand equity from those that would not appear to be as efficacious as desired. Headquarters would stop the former from occurring, but would not stop the latter. They would leave it to the local manager’s judgment as to the activity’s appropriateness, but also hold him or her responsible for its success or failure.

Similarly, Levi’s have balanced global and local control with a “thermometer” model. Marketing elements below the “freezing point” are fixed: “brand soul” or essence and logos are standardized worldwide. Above the freezing point, product quality, pricing, advertising, distribution, and promotions are all “fluid,” meaning each international division can handle

the marketing mix elements in any way that they feel is appropriate for their region.

McDonald’s also have allowed countries and regions more latitude to customize around their basic layout and menu staples. In China, they substitute corn for fries in Happy Meals, some stores in United States blend fruit smoothies, and Australia and France have Starbucks-like lounges. In cities plagued with horrendous traffic problems – for example, Manila, Taipei, Jakarta, and Cairo – they actually deliver McDonald’s meals via fleets of motor scooters.

Brand architecture. Companies such as Kraft, Unilever, and P&G market global brands in countries all over the world, but they also have a number of local brands or “local treasures” as they sometimes call them, which have built up strongly resonant consumer franchises (Schuiling and Kapferer, 2004). Unilever’s local jewels, for example, include Ben & Jerry’s ice cream, Suave hair care, and Wish-Bone salad dressings in the United States; and Bovril and Marmite spreads, Peperami spicy salami, and Pot Noodle noodle snack foods in the United Kingdom. For companies with such varied brand portfolios (*see* MANAGING THE GLOBAL PRODUCT PORTFOLIO), their challenge in many cases is to ensure that the global brands stay relevant in local markets and, on the other hand, local brands are able to compete on a global stage in their home market or potentially even elsewhere (Douglas *et al.*, 2001).

Nestle are a company that have benefited significantly from a balance of global and local control. Some decisions, such as branding, follow strict corporate guidelines. The company have 10 *worldwide corporate* strategic brands, including Nestle, Nescafe, Maggi, and Carnation. There are 45 different strategic *worldwide product* brands, including Kit Kat, Coffeemate, and Crunch. There are 25 *regional corporate* strategic brands, including Perugina, Findus, and Stouffer’s. There are 100 *regional product* brands, including Eskimo, Taster’s Choice, and Go-Cat. Finally, there are 700 *local strategic* brands that are important to particular countries, including Brigadeiro in Brazil.

Most other decisions, however, are primarily decided upon by the local managers. Nestle’s policy is to recognize that they are foreigners in

any country outside Switzerland and to simply let the local managers run most of the business operations. For example, the company do not do corporate-level strategic planning. Instead, the top managers in each region tell headquarters what they plan to do and a combination of bottom-up or top-down approaches is used to finalize a strategy. Headquarters meet once a year with each of the country managers to discuss strategic issues. The bottom line resides with headquarters, and they have the power to force the local managers to adopt a policy, if necessary. This happened with ice cream in the United States.

The country manager classified the product as a dairy product, whereas headquarters viewed it more strategically as a frozen confectionery. The country manager proposed machines and cones, and headquarters countered with self-manufacture and direct store delivery. Today, Nestle are a strong number two in the ice cream impulse segment, and have invested in a 17% stake in Dreyer.

Establish operable guidelines. Brand definition and guidelines must be established, communicated, and properly enforced so that marketers in different regions have a good understanding of what they are expected to do and not to do. The goal is to clearly set the rules for how the brand should be positioned and marketed. Hence, everyone within the organization understands the brand's meaning and can translate that meaning to satisfy local consumer preferences.

Aaker and Joachimsthaler (1999) put it this way: "Global brand leadership means using organizational structures, processes, and cultures to allocate brand-building resources globally, to create global synergies, and to develop a global brand strategy that coordinates and leverages country brand strategies." Specifically, they advocate four key ideas:

- stimulate the sharing of insights and best practices across countries;
- support a common global brand-planning process;
- assign managerial responsibility for brands in order to create cross-country synergies and to fight local bias; and
- execute brilliant brand-building strategies.

Brand definition and communication is aided with some sort of document that details what the brand is and what the brand is not. In terms of brand documentation, Coca-Cola have a strategy document that clearly articulates their strategy and how the brand positioning is manifested in various aspects of the marketing mix elements. This document sets out the parameters for the brand and, therefore, determines how much is left to chance. Similarly, McDonald's operating manual imposes rigorous worldwide controls (e.g., the 19 steps to cook and bag French fries). Nestle ensure that branding decisions at least follow strict corporate guidelines.

Brand mantras may be especially helpful in providing easily understood brand guidelines. A *brand mantra* is an articulation of the "heart and soul" of the brand. Brand mantras are short, three- to five-word phrases that capture the irrefutable essence or spirit of the brand positioning. Their purpose is to ensure that all employees within the organization and all external marketing partners understand how the brand should be projected to the consumers so that employees and partners can adjust their actions accordingly. As noted above, Nike's brand mantra is "authentic, athletic performance" and effectively translating that in different markets has been one of their keys to global success.

Disney's brand mantra has been "fun, family entertainment." To establish global guidelines for licensing, Disney assign them to one of the three categories: (i) acceptable to license without permission (e.g., T-shirts); (ii) not permissible to ever license (e.g., toilet paper); and (iii) requires validation from headquarters to license (about 20 categories – e.g., air fresheners). Internationally, Disney noticed that these "gray areas" grew bigger and more numerous. The company also try to identify those product groups that may be more amenable to localizing than others. For example, movies cannot be tailored for the European market because it is difficult to determine what will be attractive to those consumers. On the other hand, certain items in the Disney store may sell well in Germany but not in Japan.

Finally, for all of this to work, there must be effective lines of communication and means to transfer knowledge within and across regions. Coca-Cola stress the importance of

having people “on the ground” who can effectively manage the brand in concert with their headquarters in Atlanta. For example, to facilitate coordination, much training occurs in headquarters, a sophisticated e-mail and voice mail system is in place, and global databases are available. The goal of this heavily integrated information system is to facilitate the local manager’s ability to tap into what constitutes “relevance” in any particular country and then communicate those ideals to headquarters or other parts of the region. Coca-Cola are thus able to transfer product ideas within and across regions. Japan, long a hot-bed for new product ideas, has been joined by other Asian markets such as China as the company expands their product portfolio to include water, juice, tea, coffee, and even “gel” beverages. From China came Minute Maid Pulpy; from Hong Kong came Nestea with Aloe Pulp.

Effectively transferring successful marketing ideas from one region to another region is a key priority for many firms. Rather than developing global products for jointly owned Renault and Nissan, CEO Carlos Ghosn has mandated that companies design for local tastes and have the flexibility to export the design to other regions to tap into similar consumer trends. As an example, the no-frills Logan was developed by Renault for Eastern Europe and Latin America but it found another home in France. Along with the specific products that cross a region, ideas and a way of thinking may also transfer in the process. Ghosn teamed Nissan and Renault with Bajaj Auto to sell a \$3000 car in the Indian market in part to infuse those companies with India’s low-cost design thinking: “They understand frugal engineering, which is something we aren’t as good at in Europe or Japan.”

CONCLUSIONS

Increasingly, it is imperative that marketers properly define and implement a global branding strategy. Although global branding offers many potential benefits to a firm, there are also significant risks. Despite these potential pitfalls, a number of marketing pioneers have successfully established global brand powerhouses over the last decade or so. On the basis of the experiences and practices of leading global brands and the

learning from academic research, this article has identified three key steps to building a successful global brand: (i) understand the global consumer context; (ii) build proper global marketing infrastructure; and (iii) strike a balance in global brand management. Although building a strong global brand can involve a number of complex issues and considerations, successfully accomplishing these three steps can increase the odds of success.

base of the pyramid markets: culture
insights and marketing implications

Cheryl Nakata

INTRODUCTION

Much of the world's population is poor. According to the World Bank, 2.7 billion persons, representing over half of the world's population, live on less than \$2 a day. Within that group, 1.1 billion subsist on just \$1 per day. The greatest concentrations of poverty occur in developing countries and regions, such as China (596 million) and sub-Saharan Africa (514 million) (see EMERGING MARKETS). As a market, the poor in these geographies – termed the “base of the pyramid” or BOP – has been largely ignored (Prahalad, 2005).¹ Businesses have focused instead on the middle and top of the pyramid, selling products to wealthier consumers in developed or developing countries.

However, the immense size of the BOP market and relative dearth of competition for its loyalty spell significant growth opportunities for global companies (see GLOBAL MARKETING STRATEGY). Firms are beginning to seize these opportunities, specifically by creating new, or significantly adapting existing, goods and services for the unique needs of BOP consumers. Examples are Hindustan Lever, which developed a disinfectant soap for villagers in India to reduce widespread diarrheal disease; Haier, which designed a small washing machine priced at \$37 for first-time white goods buyers in China; and Nokia, which produced a \$25 cell phone, featuring a speaking alarm clock and an iconic address book, for illiterate Brazilians. These firms are hoping to not only generate significant new revenues, but also fulfill a mandate for greater corporate social responsibility. By providing the poor with access to quality, value-laden products and services, such enterprises aim to open the door of full participation to persons historically excluded from the global marketplace (see GLOBAL MARKETING ETHICS).

Despite the opportunities, most businesses find the idea of tackling the BOP market, with all its attendant challenges, daunting.

Buyers in this market are characterized as largely illiterate, in poor health, of meager resources, inaccessible by media, geographically isolated, and ignorant about consumption (Prahalad, 2005). Marketing to such buyers requires deep expertise to work within these constraints. A particular need is cultural understanding (see SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE). Compared to the top or middle of the pyramid, the BOP is culturally remote to businesses and their managers, who are generally unfamiliar with and have not experienced the severe and constant deprivations of subsistence living. These deprivations result in a distinctive way of life, that is, a culture that affects consumption attitudes and practices (Viswanathan, 2007). Effectively addressing the BOP market, then, rests on understanding the BOP culture.

The purpose of this article is to provide insights on the BOP culture and explore implications for firms marketing to the BOP, perhaps the last, largest, and most difficult market frontier. Because business interest in the BOP is emergent, it may be opportune to elaborate on cultural matters, informing and guiding future strategies and approaches.

A CULTURE OF POVERTY

From the perspective of outsiders, BOP consumers live a dark and hopeless existence. Grinding poverty means dehumanizing routines for survival, such as scavenging trash hills for tossed food and foregoing medications when desperately ill (Hill, 2002; Viswanathan, 2007). Threats to shelter, security, and all forms of well-being are unrelentingly harsh. Fifty years ago, Lewis (1959) provided an indelible portrait of life at the bottom titled *Five Families: Mexican Case Studies in the Culture of Poverty*. The ethnography vividly described the daily struggles of the poor. More importantly, Lewis articulated and received wide attention for his treatise that the poor possess a unique culture. According to Lewis, the poor respond to material scarcities with negative attitudes and behaviors, such as alienation and crime. These habits of thought and action are rooted in early childhood and transferred within families (Lewis, 1966, p. xiv):

2 base of the pyramid markets: culture insights and marketing implications

The culture of poverty is not only an adaptation to a set of objective conditions of the larger society. Once it comes into existence it tends to perpetuate itself from generation to generation because of its effect on the children. By the time slum children are age six or seven they have usually absorbed the basic values and attitudes of their subculture and are not psychologically geared to take full advantage of changing conditions or increased opportunities which may occur in their lifetime.

Lewis' view has been highly influential in formulating public and welfare policies, as well as popularizing the notion of a unique culture of poverty. The question raised is, whether the BOP has a "culture of poverty" as described by Lewis? The argument here is that while the BOP may have distinctive cultural characteristics, these characteristics are not entirely negative or as deterministic as portrayed by Lewis. Critics of Lewis point out that a subtle but important precept of Lewis' theory is that the poor exist within a self-defeating culture of their own making (Leacock, 1971, pp. 7–37): they are unwilling and/or unable to pull themselves up by their bootstraps to plan for, work toward, and live a better future. Low aspirations, weak self-discipline, and high social exclusion combine to doom them to short, hellish existences.

Studies suggest – and the interview is forwarded here – that while the poor face extraordinarily difficult circumstances, they desire and dream no less than the nonpoor for better lives. BOP persons want more like everyone else. Critically, if given the chance to save money, start businesses, educate their children, care for their physical health, and lead productive lives in civil harmony with others, they will do so (Hill, 2002; Jones and Lou, 1999; Viswanathan, 2007). The difference is that externalities, experiences, knowledge, and resources limit what they do achieve. In other words, the poor do not inherently lack moral fortitude or agency to change their lives; instead, what they lack are the means and opportunities to live differently. The choices available to them are fewer and thus their decisions differ, all of which result in a culture that is more complex and dynamic as well as less predictable and pathological than Lewis suggested.

A CULTURE WITH PARADOX

The temptation in broaching the BOP, as with any culture, is to assign it a monolithic quality. "All of the poor are _____" (fill in the blank) captures the sentiment. However, the BOP cannot be so simplistically characterized. Within the culture of poverty – consistent with its complex and dynamic nature – there is also a major paradox. The argument is that the BOP is simultaneously *both* poor and rich, and specifically that BOP consumers are deprived in very fundamental ways yet endowed with other resources. It is argued that the deprivations of the poor, which are deep and dehumanizing, should not be dismissed. This assertion of paradox has been made to encourage a deeper look at the market.

The BOP has little economically. This condition is obvious. What is less apparent is that the deprivation is accompanied by many others. As the Nobel Laureate Sen (1999) observed, poverty is not just the scarcity of economic means; it is more broadly and subtly multiple forms of deprivation or "unfreedoms." Among these unfreedoms are social isolation due to the stigma of poverty, physical illness from unsanitary living conditions, psychological distress through constant threats of violence, low employment because of limited schooling, and fatigue from labor-intensive drudgery (e.g., fetching water for hours each day because there is no indoor plumbing or a nearby drinkable water source). Even exclusion from the marketplace, or not having access to quality goods within one's means, is a deprivation. Additionally, the poor live under conditions – economic, sociocultural, and political-regulatory – that disadvantage them relative to their nonpoor counterparts. Minimal job opportunities, inadequate housing, atomized retailing, media darkness, high prices, and low choice, for instance, are typical of impoverished communities.

Importantly, too, BOP individuals suffer from associated emotional and cognitive stresses. Because of severely restricted incomes, they hold onto possessions that would be considered unacceptable by others who are better off (e.g., having only one pair of worn and tattered jeans), and do not buy items most others own and take for granted (e.g., new pencils at the start of the

school year). The comparative lacks generate emotions of rage, fear, and hopelessness (Hill, 2002). Low literacy, numeracy, and education also contribute to cognitive difficulties in making informed purchasing choices. For example, the inability to calculate price per ounce or read special promotion signs leads to buying heuristics such as always getting the same product, looking for the smallest size regardless of price, and focusing on a single product attribute rather than trading off among multiple attributes (Viswanathan, Rosa, and Harris, 2005). The poor are aware and ashamed of their limited “capabilities” in Sen’s parlance, creating stressful shopping and consumption experiences.

At the same time, such lacks stand in stark contrast to the considerable internal and external resources of the BOP. BOP persons have been observed to be enormously creative given the constraints they live under (Subrahmanyam and Gomez-Arias, 2008). Their inventiveness reflects an internal fortitude or resilience in the face of significant challenges (Sen, 1999). For instance, while their purchases may not be optimal in the environments of abundance surrounding middle- or upper-income consumers, BOP individuals have developed sophisticated buy and use strategies that imaginatively stretch their budgets in their context of scarcity. Typically, BOP consumers live in fragmented retailing environments, so there are only a few stores nearby carrying small inventories of limited product choice. Even in these conditions, BOP consumers manage to negotiate purchases with retailers, demanding and receiving quality products contrary to the belief that the poor buy only the cheapest goods (Viswanathan, 2007). Along with such internal resources, these consumers have external resources that enable them to know of and obtain what they need. Their communities are characterized by tight social networks leveraged for this purpose (Subrahmanyam and Gomez-Arias, 2008; Viswanathan, 2007). Families, neighbors, and friends help them make purchases they may not be able to afford on their own. And small retailers, with whom they have forged strong ties in rural settings, provide credit and customize purchases where no alternatives (e.g., banks or wide-assortment

stores) exist. In short, the BOP culture is characterized by a paradox of enormous scarcity on the one hand and an abundance of social, noneconomic capital on the other.

A CULTURE EMBEDDED AND SHAPED

Another aspect of the BOP culture is that it is embedded in and shaped by other cultural forces, specifically, consumer culture, national culture, and globalization, as depicted in Figure 1. Consumer culture refers to shared meanings and unifying values tied to consumption (*see* SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE; GLOBAL CONSUMERISM AND CONSUMPTION). While the consumer culture is more nascent in developing countries relative to industrialized settings, it, nonetheless, presents and projects values, aspirations, and behaviors whereby individuals formulate and act upon social identities through consumption. That the consumer culture exists in subsistence economies like Sri Lanka’s and Turkey’s is evident in the awareness and purchase of global brands such as Coca-Cola and Nestle even among persons who supposedly cannot afford them (Ger, 1997). The goal of marketers is to develop a strong consumer culture through which the BOP culture is encouraged to search for and purchase particular products and services. In other words, the consumer culture helps shape BOP culture. Over time, the BOP culture likewise influences consumer culture.

An example of this dynamic is Nokia’s marketing efforts in India, which has altered the local BOP culture. India is the fastest growing and third-largest mobile-phone market in the world with approximately 220 million users. Nokia aggressively entered the market several years ago and captured the lion’s share of 60% by introducing basic phones priced affordably for the low-income consumers (around \$20) as well by offering full-featured, more expensive models for higher-income individuals (upwards of \$1200). Accompanied by broad distribution and heavy brand advertising, Nokia phones have become pervasive throughout India, including in poor rural villages. Besides low pricing, Nokia further addressed the needs of rural villagers by adding a flashlight or torch feature to its phones,

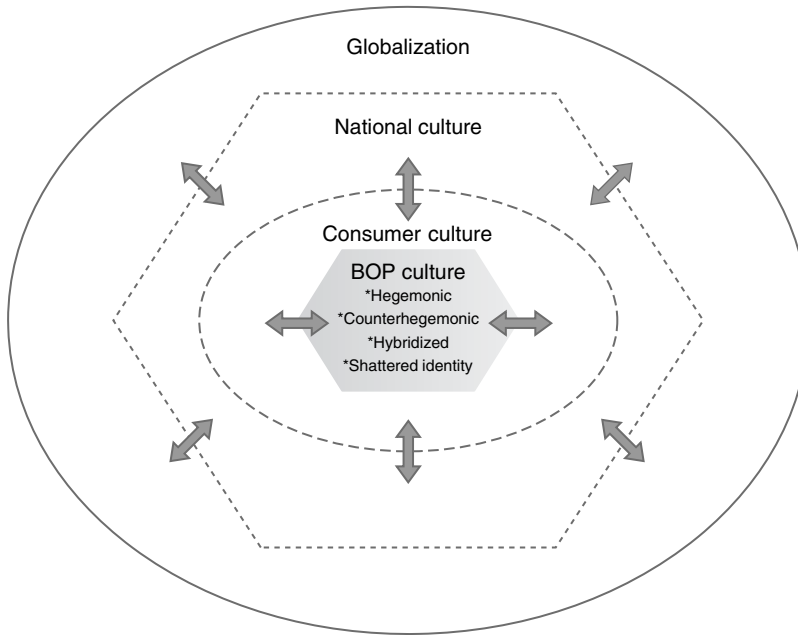

Figure 1 BOP culture as embedded, shaped, and heterogeneous.

given that electrical lighting is spotty and unreliable in these areas. Nokia's efforts to create a consumer culture have paid off handsomely in terms of high demand for its mobile phones, even among the poor. As a consequence, the BOP culture in India has been transformed. The poor, or BOP, consumers have embraced the phones and incorporated them into their daily lives, fundamentally altering how they socialize, do business, entertain themselves, and communicate with one another (www.ibef.org).

The second force affecting the BOP culture is national culture. National culture reflects the customs and traditions of a country. While no national culture is completely consistent or integrated, there are some shared patterns of heart and mind that influence a country's citizens (Hofstede, 2001). Through religious, political, and educational institutions, national culture exerts an influence on and is, in turn, influenced by consumer culture. This means that the BOP culture is indirectly affected by national culture, reflecting a complex layering of cultural interactions. An example of such interactions is given by Viswanathan (2007), who describes how the poor in some societies avoid taking on

debt to make purchases because of the norm of face loss or social embarrassment associated with credit. Thus national culture, in the form of face saving, affects the consumer and BOP cultures. It affects both cultures by lowering the desirability of making purchases without cash in hand, and encouraging other means to engage in purchase behaviors, including borrowing funds from friends, families, and neighbors. Furthermore, Viswanathan points out how collectivism, a national culture value, injects itself in the marketing and consumption practices of these poor communities. Collectivism fuels word-of-mouth effects among consumers, strengthens ties between marketers (especially retailers) and customers, and facilitates group-based financing, purchasing, and use of products that would not be affordable on an individual basis. An illustration of the latter is the pooling of monies on a monthly basis among community members to provide a loan to one participant for a major purchase or to support a business, with the understanding that the monies are to be repaid and then used to provide a loan to another member the following month.

Finally, the third cultural force affecting the BOP culture is globalization. Globalization creates shifts – sometimes quickly, sometimes slowly – in the social, economic, political, and technological landscapes of developing countries. Globalization therefore also affects BOP populations and their culture within these countries. For instance, globalization (specifically, its promise of industrialization and economic growth) can motivate a government to liberalize its trade policies by permitting the wider importation of foreign goods and advertisements, as has occurred in China, Brazil, and Indonesia, among others. BOP consumers are subsequently exposed to new goods and promotion messages, being informed about the availability of, and offered perhaps for the first time, branded detergents, ice cream, washing machines, and other products of good quality that are taken for granted by the more affluent. Through continual exposure to such items and advertisements, these consumers individually and their BOP culture collectively are altered, both in terms of product purchases and usages as well as beliefs about the nature, quality, and goals of their lifestyles as reflected in consumption choices. As noted by Ger, with respect to developing countries (Ger, 1997, pp. 110–111), “Because development includes modernization and marketization, the increased availability, display, and advertising of mostly foreign products fuels aspirations for the good life and raise consumption expectations . . . the image of the good life in less affluent countries is one of being a successful participant in a consumption-oriented society . . . There is widespread desire for the goods that prominently surround people in the less affluent world.”

A CULTURE HETEROGENEOUS

As a consequence of embeddedness in consumer culture, national culture, and globalization, the BOP culture is actively under negotiation. Not all the forces encompassing and shaping the BOP culture move in the same direction, and the BOP culture has its own pulls and preferences. Thus it represents an area of contested change. For instance, globalization may promote the acceptance of foreign goods by the BOP, but national

culture may do the opposite, fanning the flames of nationalism and rejecting the encroachment of alien influences. The BOP culture is caught in the middle, subject to conflicting tensions. The term *negotiation* means that the BOP culture is in a fluid state, with a heterogeneity of coexisting meanings and SUBCULTURES. These heterogeneous meanings and subcultures reflect a range of reactions to and engagements with the consumer culture, national culture, and globalization. More specifically, following Askegaard, Arnould, and Kjeldgaard (2005) and Ustuner and Holt (2007), it is proposed that those meanings/subcultures fall into four categories: hegemonic, counterhegemonic, hybridized, and shattered identity. These categories are also represented in Figure 1.

When consumers encounter a culture not their own, such as by migrating from a traditional rural setting into a contemporary urban city – as has occurred to 1 billion transplants throughout the developing world, representing the largest human migration in modern history – they develop identity projects that help them navigate the contradictory discourses (*see* GLOBAL CONSUMERISM AND CONSUMPTION). For some, navigation is an attempt to assimilate the other culture, embracing it while rejecting their own. This is termed the *hegemonic* response, whereby the other, now surrounding or dominant, culture is taken and absorbed. It is truly a project of assimilation in that it entails discarding habits of thought, feeling, and action, and concomitantly acquiring unfamiliar ones. An example of a hegemonic response is Penaloza’s (1994) study of Mexican American immigrants, some of whom took on American ways of life while abandoning their more traditional and less consumption-oriented culture.

A second response is one of resistance. Termed *counterhegemonic*, individuals attempt to retain their culture of origin, reinterpreting it yet staying true to its moorings, within the new culture. This response is primarily one of putting at bay the other culture, though it is not pure rejection in that a few selected symbols of the other culture are adopted. An example given by Ustuner and Holt (2007) is of Turkish village women who move into squatter enclaves in a major Turkish city. They purchase TVs, video

cameras, and other Western goods while holding onto a “country bumpkin” lifestyle, such as by continuing to eat meals on the floor as they did back “home.” Importantly, even these symbols of the other culture are used in ways consistent with, and reshaped into, the old or original culture. Thus, for example, freezers are shared. A whole cow is slaughtered, but then each family’s share of meat is stored in the freezer, all in keeping with traditional communal practices. In essence, though deterritorialized (i.e., having moved physically away from their villages), the women reestablish their rural habitus in the urban context.

A third response is termed *hybridization*. Here, two or more cultures are truly merged to create a third, new culture. Consumers mix and match identity positions, interpreting and making use of majority and minority discourses. This is an existentially challenging endeavor, but can be managed by some persons with little difficulty. A BOP consumer taking this route could, for example, bring together elements of his/her native local culture, for example, habits of food preparation from the rural community, with those of the national culture, for example, ways of dressing from the capital metropolis.

Finally, when a new culture is aspired to while the old is rejected, but the individual experiences neither as fully his or her own, perhaps as a consequence of class distinctions too great to traverse (possessing inadequate social, cultural, and economic capital to make the transition), the result is termed a *shattered identity* project. This state is experienced as one of futility, as the individual lives unhappily in the nether world between two cultures. Ustuner and Holt (2007) provide rich descriptions of such a state among young women who come from villages and aspire to the urban life of ease and abundance. However, failed attempts to marry outside their relatively poor and uneducated circles results in having to remain in their squatter communities, dejected about their current lives and futures.

Together, these four categories represent the spectrum of possible responses by the BOP in relation to its cultural milieu. The categories have been put forth to point out that the BOP culture is not uniform, and that any acculturation enterprise it undergoes is a rich, nuanced process with varied forms of adaptation.

MARKETING IMPLICATIONS

In view of the above, there are several implications for marketers. One implication is that since the BOP does not differ in life aspirations so much as opportunities with the middle and top of the pyramid, per the revised poverty of culture thesis offered here, marketing strategies and tactics that appeal to these shared aspirations, such as the desire for a happy, healthy, and good life, should be effective with BOP consumers. At the same time, the restricted opportunities faced by these buyers must be addressed so that the goods and services are truly accessible, not offered as tantalizing yet unattainable prospects (see ETHICAL MARKETING AND MARKETING STRATEGY). The latter only serves to frustrate and demoralize the poor. Forms of accessibility include lowering prices so the items are affordable, and distributing products within easy, nearby reach in rural areas. Prahalad (2005) provides case studies of firms that have done both using highly inventive means.

A second implication, which stems from the insight that the BOP is a culture of paradox, is to apply marketing approaches that leverage the strengths or resources of this population while circumventing the weaknesses or lacks. As noted earlier, BOP communities tend to be rich in social capital. Through strong ties with families, friends, neighbors, shopkeepers, and others within their communities, BOP consumers obtain information and other aid in making purchases. These social resources can be leveraged in marketing, such as by relying on word-of-mouth (rather than mass) advertising; incenting retailers in personal (rather than impersonal) sales; providing collective, for example, family-based (rather than individual) forms of credit and purchasing; and organizing direct (rather than indirect) sales and distribution systems where relation marketing methods are effective. In terms of weaknesses or lacks, it has been noted that BOP individuals are hampered by a host of deprivations, among them low literacy. To help ameliorate the literacy issue, a marketing solution is to design packaging and advertising that is pictorial for ease of comprehension and, at the same time, emphasizes concrete attributes of the product or service (Viswanathan, Rosa,

and Harris, 2005). Other limitations in BOP capabilities also need to be accounted for in marketing programs to ensure their efficacy.

With respect to the embedded nature of the BOP culture, an implication is to conduct deep, not superficial, market research to fully understand the culture's multiplex and evolving nature (see ETHNOGRAPHIC RESEARCH). The encircling forces of consumer culture, national culture, and globalization impact the BOP culture, resulting in a unique, changing sociology. Figure 1 underscores that the BOP culture is best understood when contextualized. Hence each BOP market deserves firsthand examination, and should be periodically restudied to develop appropriate, contemporary marketing strategies. As an illustration, businesses engaged in BOP markets such as Procter and Gamble are finding that immersion of their staff in these communities, that is, having staff live for extended periods with poor families, is critical for obtaining insights on how best to meet their needs. While learning can be carried over from one BOP market to the next, the assumption that they are all the same and should be treated as such is as likely to be erroneous as believing all top of the pyramid markets are identical. Importantly, as well, since learning about BOP markets in general is at its infancy, now is the time to invest in significant primary market research.

A final marketing implication, which results from the insight that the BOP culture is under negotiation, is that segmentation and targeting are useful (see MARKET SEGMENTATION AND TARGETING). There may be at least four subcultures within the BOP, each of which has a distinct view and set of behaviors in relation to goods and services representing other cultures: hegemonic, counterhegemonic, hybridized, and shattered identity. The first three are to varying degrees adoptive of such goods and services, with their reasons and ways of doing so differing. Astute marketers will recognize these distinctions, segmenting the market instead of treating it as a homogeneous whole, selecting the segments more amenable to their overtures, and then customizing the marketing mix accordingly. Marketers may discover en route that there are other segments, and pursue ones that are more receptive to their companies'

particular offerings. In conclusion, the BOP market poses enormous opportunities as well as challenges for global businesses. A chief need in tackling these markets is knowledge of their culture, so that efforts by firms are thoughtful and beneficial to all concerned. This article proposes that the BOP culture is complex and dynamic, characterized by shared aspirations and limited opportunities, a paradox of lacks and abundance, embeddedness in layers of cultural influences, and heterogeneous meanings and groupings in response to externalities. Global firms can use these insights to generate appropriate and effective marketing strategies and tactics that not only open significant new markets, but serve and enhance the lives of those who have been historically marginalized.

ENDNOTES

¹ The term *BOP* is not intended pejoratively. Other terms used more or less synonymously in the literature are bottom of the pyramid, subsistence markets, and low-income consumers

global account management: the rationale and motivation

Michael Harvey and Miriam Moeller

INTRODUCTION

The coordination of customer management across national boundaries, commonly referred to as *global account management* (GAM), has rapidly emerged as one of the most prevalent corporate responses to the globalization of markets. Yip and Madsen (1996) observe that the need for GAM is driven by the emergence of global customers, global channels (*see* INTERNATIONAL MARKETING CHANNELS), high product development costs, fast-changing technology, and globalized competitors, to name a few. It was hypothesized by Birkinshaw, Toulan, and Arnold (2000) that GAM structures allow the multinational corporation (MNC)/global organization (i.e., the supplier) to increase its information-processing capacity as well as its bargaining power with regard to the global customer. The National Account Management Association has described GAM as a well-articulated management strategy and a “critical competitive weapon” and has stated that GAM “clearly represents the new frontier in Strategic Account Management” (Birkinshaw, Toulan, and Arnold, 2000). The motivation for forming and utilizing a GAM strategy varies widely: it can be due to both positive as well as negative factors (see Table 1).

Strategically, GAM teams serve to ensure that organizational components are configured to best serve global customers effectively/efficiently. In essence, GAM is a means of coordinating activities to address the needs of a single customer in multiple environmental contexts (i.e., countries, markets, etc.) and to ensure the successful coordination and management of these clients globally (Birkinshaw, Toulan, and Arnold, 2000). Thus, the responsibilities of GAM are as follows: (i) creating consistency in the application of policies throughout the world; (ii) coordination of marketing/selling activities to increase sales volume; (iii) effective utilization of marketing strategies and programs in multiple locations; (iv) efficiency of management, in that, there is a central contact of key accounts; (v)

establishing a control mechanism relative to key accounts to reduce the probability of account turnover; (vi) improve the two-way flow of communications with key accounts, thereby increasing the knowledge base to improve the quality of goods/services to these global clients; and (viii) awareness as a means to preempt local/global competitors from securing business from these critical customers (Birkinshaw, Toulan, and Arnold, 2000).

THE RATIONALE FOR FORMATION OF GAM TEAMS

The rationale for using GAM teams can be derived from a number of perspectives. First, GAM teams provide the parent organization with flexibility that other organizational configurations do not present. That being so, the ability to readily adapt to an increasingly complex global context is important for organizations as they rapidly expand their operations overseas or in configuring their strategic orientation to become more global (Harvey, Novicevic, and Garrison, 2004). Second, the team concept (i.e., being dedicated to one customer globally) increases the level of attention/focus on key decision variables of the global customer. Stated differently, the responsibility for the key account globally is that of the GAM team. This attention to consistency and coordination should alleviate internal decisions that are at cross purposes. (Martins, Gilson, and Maynard, 2004). Third, the GAM team has the ability to modify and/or change its composition (i.e., diversity of team members) to meet changes in the strategic thrust of their customer. As the client of the GAM team modifies its strategic direction (e.g., geographically, product line, or the like) the team can quickly match the direction of the GAM customer (Yip and Madsen, 1996). Thus the rationale used to justify GAM teams is that they can be disbanded/added to more easily than traditional organization structures. Given that the motivation for forming a GAM frequently is based on the expectations of a global client, the ability to shrink the size of the GAM team, as well as to redirect its strategic focus, is a critical element for deciding on using GAM teams.

Table 1 Motivation for global account management strategy.

| Proactive motivation | |
|--|--|
| | <ul style="list-style-type: none">● Increased sales of existing products/services● Facilitating introduction of new products and services● Coordination of selling/marketing efforts globally● Increased profit due to sales increase and cost containment● Means to reduce competition to supply global accounts and overseas markets● Building long-term relationships with key customers● Increasing customer dependency● Development of cooperative/synergistic relationships with key customers to ensure global competitiveness● Maintaining strategic consistency, thereby, increasing strategic “fit” with key customers● Global utilization of successful marketing and sales programs● Increased network efficiency and effectiveness globally |
| Short-run perspective | Long-run perspective |
| <ul style="list-style-type: none">● Pressures from customers to maintain global consistency of products and services● Pressures from customers to reduce prices globally● Concern relating to local competitors in certain regions getting the customer’s business● Major concern related to loss of key accounts if GAM structure is not implemented | <ul style="list-style-type: none">● Means to effect power shift to key global customers● Dependence on key customers for global sales growth● Need to provide value-added services without commensurate price enhancement● Liability to compete for global customers without GAM● Customers are demanding GAM, but economic and effectiveness justification cannot be supported |
| Reactive motivation | |

Adapted from: Harvey, M., Myers, M., & Novicevic, M. (2002). Managerial issues associated with Global Account Management, *Journal of Management Development*, 22(2), 103-129.

The fourth rationale is that the GAM team can distribute the decision making to the point closest to the consumer/environment context. Market-based decision making allows the GAM team to push decision making to the point where the environmental context can be taken into

strategic consideration. This allows the GAM team to think globally but to act locally, a key consideration in effectively addressing global clients’ needs (Harvey, Myers, and Novicevic, 2002). An example that illustrates this point is the AT&T GAM that serves other global

customers (i.e., those who require worldwide services) by providing them with a worldwide plan as opposed to a collection of individual, country-specific plans. This is not to say that the services offered by AT&T may not be differentiated, as services certainly are to some extent adapted to local environments (e.g., thinking globally but enacting local strategies). From AT&T's perspective, the challenge lies in reconfiguring the way of thinking about their customers' business and how to effectively conduct business in a global context. This modification in strategic thinking incorporates the following four factors: (i) organizational structure, (ii) management processes, (iii) personnel, and (iv) organization culture.

A fifth justification for the formation of GAM teams is to make timely global decisions. More traditional, centralized organization structures are frequently slow in making timely competitive decisions in far-flung global markets. This rationale for GAM addresses the "economies of scope" dimension of clients of the GAM. The more geographically dispersed the clients, the greater the need to move decision makers closer to the foreign markets where their decisions are being made (Brass *et al.*, 2004). By breaking down the central decision-making hierarchy (e.g., utilizing teams) into functional heterarchies, the time responsiveness for GAM clients should be enhanced (Harvey, Myers, and Novicevic, 2002).

BUILDING TRUST AND SOCIAL CAPITAL THROUGH GAM TEAMS

As the global environment becomes more competitive, strategic HR managers increasingly have to address their new competitive landscape (Bettis and Hitt, 1995). This new landscape is replete with technological advancements leading to the rise of global markets and increase in global competition. The complexity and dynamism of the new economy urges organizations to find innovative ways to cultivate and manage trust and the residual social capital. Thus, the growing importance of strategic global management illuminates the need for the assessment of "capital" within the organization to allow it to maintain its focus on core competencies and viability within the

global arena. To stay innovative and ahead of competition, HR must pursue a strategic vision addressing this dynamic and complex issue by tapping those "capital" resources that are vital in maintaining or creating a competitive advantage. One of these resources is constructing social networks to facilitate the development, growth, and management of social capital.

Putnam (1995) defines *social capital* as "the features of social organization, such as networks, norms, and trust that facilitate coordination and cooperation for mutual benefit" (p. 35). Inherent in this definition is the trusting relationship between network sources (Putnam, 1995). Because of the trust component, researchers believe that social capital encourages cooperative behavior (Fukuyama, 1995) and that social capital reduces transaction costs, because trust decreases feelings of suspicion and the likelihood for opportunistic behaviors (Putnam, 1995).

Global organizations possess numerous resources, but perhaps it is their knowledge base that is central to their competitive edge (Barney, 1991). One avenue strategic HR managers are pursuing in the quest of revolutionary knowledge is through the use of GAM teams and the next generation of global virtual teams (GVTs). GAM teams are rapidly being integrated into global organizations, because they are thought to increase speed and efficiency in the creation and transfer of knowledge (Kogut and Zander, 1996). More specifically, GAM teams are thought to enhance the conception and delivery of tacit knowledge since GVTs are characterized by their temporary existence coupled with the potential of their members to multitask simultaneously on multiple projects (Townsend, DeMarie, and Hendrickson, 1998). Because the global environment is in constant flux, it is imperative for GAM team members to develop social networks to facilitate the exchange of thoughts and ideas for the creation of new knowledge with the expectation of creating a competitive advantage. As a result of continued knowledge sharing, the current and future supplier/customer duos will benefit from this synergistic cooperation by a decrease in the learning curve, and by allowing for lower operation costs.

The relationship between organizational knowledge and its competitive advantage lies

4 global account management: the rationale and motivation

in its ability to integrate knowledge utilized in GAM teams (Nahapiet and Ghoshal, 1998). Knowledge is transferred through the GAM team members' relationships with others outside the organization (i.e., social capital). Through the development of social capital by the GAM team members (i.e., social networks), GAM can (i) gain access to financial resources (the GAM will be adequately funded to ensure project completion); (ii) augment the GAM's cultural capital (through collaboration efforts with members of varying functional and cultural expertise); and (iii) increase their human capital (by acting upon the accessibility and timely availability of novel information, the GAM members will increase their "stock" within the organization).

Additionally, those with greater levels of social capital have higher levels of human capital, because they are better positioned to identify and act upon timely information, thereby increasing their chances for more rewarding opportunities (Burt, 1997). The premise behind social capital is that it is an opportunity (Burt, 1997) created by network ties that provide access to diverse resources and information benefits. A result of such information-rich networks is the increasing opportunities for the availability, development, and dissemination of new knowledge. The benefit of such social networks for GAM team lies in the accessibility of information with a reduction in the amount of time and effort required in obtaining nonredundant information.

Social network studies have demonstrated the importance of strong network ties in transferring tacit knowledge across organizational boundaries. These social networks are developed or augmented via participation on team projects and made stronger through frequent team interaction (Bandura, 1986). The information benefits the GAM team can experience are in the access and timing of the information (Burt, 1997). Timely information provides the GAM team, and ultimately the organization, with a first-mover's advantage. Additionally, the structure of the network indicates the amount of nonredundant information that flows from sender to receiver (Nahapiet and Ghoshal, 1998). GAM teams with "rich" social networks (i.e., those made up of functionally and culturally

diverse members) are provided more rewarding opportunities to develop and deliver innovative ideas and products. However, social capital is a resource limited by the network (i.e., hierarchy and density) and by the membership that forms the network (Putnam, 1995).

Social capital theory proposes that the networks of relationships create a valuable resource for the creation of knowledge. Additionally, social capital resides within these social networks, resulting from feelings of gratitude and respect (Bourdieu, 1985). Nahapiet and Ghoshal (1998) proposed that it is the web of contacts or connections that creates the pattern of linkages, which create the foundation for social capital. Thus these complex relationships create a process in which social capital is developed and sustained through the process of knowledge transfer. Consequently, the organizations that make use of their collective expertise and knowledge tend to be more innovative and efficient, and it appears that it is the creation and strengthening of social relations that is critical to effectively transfer tacit knowledge throughout the global organization (Hansen, Podolny, and Pfeffer, 2001).

Inherent in the development of GAM teams, as with conventional teams, is the need for trust, since trust has been linked to team performance (O'Hara-Devereaux and Johansen, 1994) and may be substituted as a controlling mechanism in a global virtual context. *Trust*, another component of interorganizational GAM relationships defined by Davis *et al.* (2000), is "the willingness of an individual to be vulnerable to the actions of another person based on the expectation that the other will perform a particular action important to the individual without regard to the ability to monitor or control that other person" (p. 712). Despite the inherent importance of trusting relationships, the strength of the dimension is still dependent upon the type of relationship between the trustor and trustee. The pursuit of trust is therefore a vital component of achieving the desired state of cooperative and synergistic behaviors organizations strive for in the formation and development of GAM teams.

SUMMARY

GAM is an organizational configuration resulting from the rapid expansion of firms into the global marketplace. The GAM team essentially provides a “bridge” for the MNC to evolve into a fully articulated global organization. This organizational metamorphosis provides the organization with an interim means to address the needs of its global consumers and at the same time enables the MNC to become global in its scope. The GAM team’s success is based upon the social capital and resulting trust that is built with the key global account that the GAM services. In the future, when organizations have more insight and experience with regard to competing in a global context, newer forms of organizational structures will supersede the present GAM organizational configuration.

marketing's corporate responsibility

Nicolas M. Dahan, Jonathan P. Doh, and
Terrence R. Guay

INTRODUCTION

Corporate responsibility or, often, corporate social responsibility (CSR), is the notion that companies should operate not just on behalf of their stockholders but in the best interest of society and other stakeholders (including workers, suppliers, environmentalists, and communities). This is controversial for several reasons, particularly since it may undermine the long-held view that companies should aim to maximize the wealth of their owners. However, pressure from a variety of actors, including nongovernmental organizations (NGOs), government, and other stakeholders are forcing companies to rethink their role in society, and to seek to provide benefits to both their owners and society more broadly. The view that CSR can divert management's attention from maximizing shareholder value is countered by the fact that many corporate executives now take seriously this alternate view to strategic management. Their reasons range from agreeing with the concept of CSR (a progressive view of the role of business in a postmodern society) to wanting to avoid the negative publicity that may influence customers to take their business elsewhere (a view more in line with preserving shareholder value) to the hope that voluntary actions will preclude more costly government regulation. Evidence that CSR and economic performance are not mutually exclusive, and can even be complementary, bolsters the case that firms can "do well while doing good." Corporate initiatives in CSR can be complicated by the fact that it is not always obvious what is in society's best interest. Likewise, with regard to marketing policies, nonstockholding stakeholders have expressed expectations that may be financially costly in the short-term and hinder business growth. Socially responsible marketing may however be in a firm's long-term interest.

CONCEPTUAL DIMENSIONS OF CSR

Stakeholder and institutional theories of CSR. The idea that companies should benefit both their owners (i.e., shareholders) and society more broadly affects business in two direct ways. The first is that CSR accepts that companies must respond to the interests of stakeholders, which is a much broader set of interests than stockholders. The idea that managers should maximize the wealth of their company's shareholders is a fundamental tenet in the management and financial literature, and is widely held in practice among US companies. The economist Milton Friedman famously wrote in *Capitalism and Freedom* that, "Few trends could so thoroughly undermine the very foundations of our free society as the acceptance by corporate officials of a social responsibility other than to make as much money for their stockholders as possible" (p.135). Friedman was concerned that CSR would, in effect, lead to the private sector taking on public sector responsibilities, and that managers are ill-equipped to determine which actions will best serve society's interest. Managers, according to the mainstream view, instead should focus on actions that will increase the value of the company and, in turn, the company's stockholders. Governments and individuals can use their tax revenues and personal wealth, respectively, to achieve social goals.

Over the past two decades, stakeholder theory has challenged the primacy of stockholders in management theory and practice. Stakeholder management, stakeholder theory, and other variants of stakeholder analysis have occupied a great deal of managerial research. Edward Freeman argued that business relationships should include all those who may "affect or be affected by" a corporation. Much of the research in stakeholder theory has sought to systematically address the question of which stakeholders deserve or require management attention. Approaches to this question have focused on relationships between organizations and stakeholders based on exchange transactions, power dependencies, legitimacy claims, or other claims. Mitchell, Agle, and Wood (1997) developed a typology for classifying stakeholders. They proposed a theory of

2 marketing's corporate responsibility

stakeholder identification and salience based on managerial assessments of stakeholders' possession of one or more of three relationship attributes: power, legitimacy, and urgency. Managers should respond in priority to the claims of stakeholders who possess all three characteristics. Researchers have attempted to integrate stakeholder theory with other managerial perspectives, particularly theories of governance and agency. The stakeholder concept is more widely implemented in continental Europe, where key interest groups such as labor unions, suppliers, banks, and government officials are involved to varying degrees in corporate decision making due to tradition or legal requirements.

In a related vein, neoinstitutional theory explains CSR as a corporate response to social pressures setting expectations on how firms should structure and operate their businesses (Campbell, 2007). As societies' concerns for social issues (such as equal opportunities, labor conditions, or the environment) have grown in the past three decades, mounting social pressures have forced a lot of firms to reconsider their place in society.

NGOs are a subset of stakeholders that have become increasingly influential in shaping and expressing these social concerns in recent years. NGOs first rose in prominence in the 1980s, when a range of NGOs, including church and community groups, human rights organizations, and other antiapartheid activists, built strong networks and pressed US cities and states to divest their public pension funds of companies doing business in South Africa. This effort, combined with domestic unrest, international governmental pressures, and capital flight, posed a direct, sustained, and ultimately successful challenge to the white minority rule, resulting in the collapse of apartheid. NGOs have grown in number, power, and influence since the 1980s. Their force has been felt in a range of major public policy debates, and NGO activism has been responsible for significant changes in corporate behavior and governance. Because of the interests that many NGOs represent, including the environment, labor, and human rights, these groups are an important component in discussions on CSR. Consequently, the emergence of NGOs seeking to promote

more ethical and socially responsible business practices is beginning to cause substantial changes in corporate management, strategy, and governance (Doh and Teegen, 2003). However, Bhattacharya and Korschun noted that so far, "there has been scant attention in the marketing literature on how these groups [nonprofit partners and nongovernmental organizations] function and what effects they have on constituents' perceptions" (2008, p. 114).

Conceptual applications of CSR to marketing.

Bartels (1967) offered a visionary theoretical approach of the social responsibilities and ethics of marketing. He detailed a model very much in line with the aforementioned stakeholder and neoinstitutionalist theories, viewing marketing as a socially embedded process, rather than a purely economic activity. He stressed that marketing operates in a social space where marketing officers must address participants' expectations, which become institutionalized into norms of behavior over time.

As the use of marketing became pervasive in the 1960s and 1970s, and irresponsible policies were uncovered (such as Nestlé's infant formula or Ford's Pinto model), social expectations for its proper practice rose. This point is summarized by Lavidge (1970), "as the impact of marketing on society increases, so does the social responsibility of marketing people" (1970, p. 28). Initially, these expectations were particularly shaped by the new consumerist movement (Abratt and Sachs, 1988). This led to a changed outlook on the insertion of marketing in society, attempting to focus marketing on consumer welfare (improving quality of life) in a sustainable manner. This challenge has been taken on by three conceptions of responsible marketing. Historically, the first stream of research has been a systems-based holistic approach coined "macromarketing," viewing the economic system of production, delivery, and consumption as embedded in social, legal, and political systems (Layton and Grossbart, 2006). This is rather similar to the more recent approach of "societal marketing" (Abratt and Sachs, 1988). A barely emergent view is called the "stakeholder marketing perspective," advocating an outside-in approach that addresses the expectations of various constituents rather

than focusing on an inside-out approach that starts with the firm and its bottom line. This new stream also incorporates the latest developments in stakeholder theory, moving away from the hub-and-spoke view where the firm establishes one-on-one relations with various stakeholders, to a more realistic view based on complex networked relations (Bhattacharya and Korschun, 2008).

The extent of corporate commitment to CSR. The implication of the notion of CSR is that companies should include in their decision-making the impact of their actions on a range of issues, including their employees, the ecological environment, the communities in which they operate, political institutions and processes, and poverty and economic development, among other issues. Many companies have responded by undertaking a number of initiatives addressing these social issues.

There is some debate as to whether such efforts reflect an embrace of CSR by companies, or are simply weak attempts to divert the attention of critics at a minimal cost (Vogel, 2005) or acts of cynicism, simply pretending to care in order to boost sales. "Greenwashing," for example, has come to refer to public relations initiatives by companies to present themselves as ecologically minded, when, in fact, little change has taken place. This is why Brønn and Vriani (2001) foresaw a rise in skepticism in public opinion, as more firms embrace CSR without being truly committed. Other critics argue that the voluntary nature of CSR schemes means that competitor companies are not bound to follow, and may have a cost advantage. Finally, some believe that companies undertake CSR policies to forestall more stringent, and possibly more expensive, government regulations. Nonetheless, there is some evidence that a new generation of managers is rising to positions of influence in companies, and that there is a greater awareness of the societal impact of companies and interest in addressing such concerns.

CSR and performance. An additional variant of research related to the role of the corporation in modern society comprises those efforts designed to develop and test models of corporate social

performance, CSR, and corporate social responsiveness. Empirical studies and reviews of these efforts suggest a link between corporate social responsibility/performance and the economic performance of the corporation (Cochran and Wood, 1984; Griffin and Mahon, 1997). Such relationships suggest that incorporating stakeholders into the strategy-making process may generate social benefits that yield higher financial returns.

Contrary to popular belief, companies are not always opposed to implementing CSR policies or the enactment of environmental regulations (Prakash, Krutilla, and Karamanos, 1996). If the costs of implementing environmental agreements are diffuse and the benefits concentrated, they will support such agreements. This insight suggests that when stakeholders are successful in urging the widespread adoption of standards, corporations may support agreements if they are able to share the costs while preserving individual benefits. In fact, there may be competitive advantages to doing so (*see COMPETITIVE ADVANTAGE*). Companies that conform to environmental regulations promulgated in one jurisdiction gain global first mover competitive advantages when other countries later adopt such standards. Hence, companies may willingly adopt international labor or environmental policies if they believe that such codes will eventually become standard in their industry.

Some companies have incorporated CSR so deeply into their mission statements, corporate culture, and products that they use it as the basis of their competitive strategy. They also find that there is a segment of consumers who make buying decisions based on their perceptions of a company's commitment to CSR (*see ENVIRONMENTAL CONSUMER BEHAVIOR*). Companies can thus differentiate themselves from their competitors, as Green Mountain Coffee Roasters, Whole Foods Market, Google, and Timberland have done. Even global companies in otherwise controversial industries sometimes use CSR to distinguish themselves from competitors (*see INTERNATIONAL RETAILING*). After facing intense criticism for not being socially responsible in Nigeria and elsewhere in the 1990s, Royal Dutch Shell began to champion CSR. As such, the company is regarded by many

4 marketing's corporate responsibility

stakeholders as more committed to alternative energy, minimizing environmental damage, and improving community relations than peers such as ExxonMobil.

In reviewing the emergent influence of CSR, research suggests that firms experience benefits from improving their social, labor, and environmental performance. These benefits can result from competitive advantages that emanate from improved efficiency and performance and also from reputation and goodwill that result from positive perceptions of the corporation. Further, returns may increase for those firms that adopt such standards because they receive protection or insulation from criticisms. Negative images and reputation will fall on those firms that are perceived to be acting contrary to public interest. In addition, as some firms adopt CSR practices, others may follow, generating a dynamic, reflexive process. Hence, there is motivation for companies to seek collaborations and partnerships with stakeholders under certain conditions.

More specifically, with regard to responsible marketing, the same debate over the economic return of these investments exists and points to mixed empirical results (Abratt and Sachs, 1988). Empirical studies have tested the impact of either CSR policies or specific cause-related marketing initiatives on consumer behavior. The lack of consistency in the results may be due to at least three factors. First, negative CSR information about a firm has been found to have a higher (negative) influence on consumers' product purchase intentions than positive CSR information do (Bhattacharya and Korschun, 2008; Sen and Bhattacharya, 2001). In this sense, responsible business may be more about minimizing the risk of revenue losses than maximizing revenues. Second, different stakeholders have different expectations. Thus, while supporting a certain cause may result in increased purchases from one type of constituency, it may have no effect or even a negative effect on others (Sen and Bhattacharya, 2001). For example, Domino's Pizza faced a boycott from the prochoice movement in the 1980s because the founding CEO James Monaghan was a prolife fervent Catholic who had personally supported financially the antiabortion movement. Third, these investments may yield to long-term

benefits, which do not appear immediately (Abratt and Sachs, 1988). With this caveat about the existence of mixed results, as is the case for general studies of the impact of CSR on corporate financial performance, the majority of marketing studies do point out to a positive impact of responsible practices on consumer behavior (Brønn and Vrioni, 2001; Sen and Bhattacharya, 2001). This impact is obviously higher when the firm resorts to cause-related marketing, that is, actively communicates its commitment to a social cause to its consumers. Such initiatives can generate positive media coverage, build corporate reputation, motivate employees and ultimately differentiate the firm's product or service from the competition (Brønn and Vrioni, 2001).

CSR IN PRACTICE: CHALLENGES AND OPPORTUNITIES

Challenges. The main challenge in trying to meet social expectations is that these expectations vary across stakeholders as well as across countries (due to differing cultures, religions, political and legal systems, levels of economic development: Brønn and Vrioni, 2001). As pointed out by Lavidge (1970), these expectations will also evolve over time: "some practices which today are generally considered acceptable will gradually be viewed as unethical, then immoral, and will eventually be made illegal" (1970, p. 25). This is why in many instances it is not obvious which corporate action is in society's best interest and which makes CSR implementation complicated, if not controversial.

CSR pressure is more prominent in certain industries or among specific companies that provide goods and services deemed undesirable or harmful to the general public. Companies in the tobacco industry are an obvious example, as is the oil industry. But even companies with otherwise positive contributions to CSR can face considerable criticism when one part of their business comes under scrutiny. Since the 1970s, consumer groups in the United States and Europe have urged the boycott of products sold by Nestlé because the Swiss company markets its infant formula to mothers in poor countries as a substitute for breast milk. Critics contend

that such practices are not socially responsible, since the formula is often mixed with contaminated water, mothers are ill-informed about the relative benefits of breast milk, and scarce financial resources are spent unnecessarily by some of the world's poor. Although Nestlé eventually changed some of its marketing practices to abide by an international code of conduct on breast milk substitutes, allegations that the company was providing health facilities with infant formula at prices below the cost of production instigated another round of boycotts (see ETHICAL MARKETING AND MARKETING STRATEGY).

Nike learned this lesson in the 1990s when the company was accused of manufacturing footwear and other apparel in sweatshop conditions, mainly in Asia and Central America. One of the key complicating factors was that Nike did not manufacture anything—it outsourced the production process to other companies which, in turn, created a complex network of suppliers (see GLOBAL SOURCING STRATEGY: AN EVOLUTION). Instead, Nike focused its attention on marketing its products to consumers. At first, Nike countered that the sweatshop issue was not the company's problem, since third party companies employed the workers who made Nike products. The criticisms grew more intense, and pressure from the media, consumer boycotts, and labor-oriented NGOs forced the company to develop a set of rules that its suppliers were required to abide by. These included prohibiting child labor, reducing harassment, and improving basic working conditions. While this may have satisfied some of Nike's critics, the actions produced ambiguous consequences. Children who might otherwise have worked in factories turned to other, more hazardous, occupations. Some women who had sought employment to enhance their independence and access to financial resources lost their jobs. Labor issues like this force companies to wrestle with the question of what it means to be socially responsible. From the perspective of Western countries in Europe and North America, labor conditions in developing countries may appear demeaning and exploitative. But from the perspective of emerging markets, the jobs provided by multinational corporations

(MNCs) provide opportunities for economic development (see EMERGING MARKETS). Companies seeking to be socially responsible need to think hard about the consequences of their CSR strategies.

For some companies, operating in countries where governments are authoritarian, repressive, and corrupt is unavoidable. This is especially true for the natural resources and extractive industries. It is common for such companies to be criticized for cooperating with repugnant regimes, and even strengthening them through the tax revenues provided by foreign investment. The oil company Unocal has faced intense criticism for building a pipeline in Myanmar (formerly Burma), allegedly with forced labor provided by the country's military junta. Other MNCs have withdrawn from Myanmar as a result of pressure by governments, consumers, and shareholders in the United States and Europe, who argue that companies have a social responsibility to not support a brutal regime. Similarly, the Canadian energy company Talisman was forced to sell its stake in an oil project in Sudan, after human rights groups accused the company of providing the government with the necessary revenues to wage a civil war, and major shareholders threatened to sell their shares. Trade sanctions present a related kind of CSR dilemma for companies, since they may be required to withdraw from markets that their home or other governments disapprove of, usually for political reasons (see EMBARGOES AND SANCTIONS).

Opportunities. Environmental sustainability, or meeting the needs of the present population without compromising the ability of future generations to meet their own needs, is an increasingly popular concept in the CSR arena. Companies across every industry are urged to reduce their environmental impact, "carbon footprint," and use and disposal of resources. So, for example, companies in the extractive industries like mining and oil are encouraged to minimize their environmental impact by changing production methods or repairing damage. Some timber companies plant new trees after cutting existing ones. A small but growing number of manufacturing companies utilize a closed-loop supply chain, which aims

6 marketing's corporate responsibility

to reuse or recycle materials throughout the production process, and to take back products when they have reached the end of their useful life (*see* SUPPLY CHAIN MANAGEMENT STRATEGY). Still other companies seek to reduce their environmental impact and energy use in factory and office design. It is fair to say that all of these decisions are a combination of CSR efforts, as well as economic and competitive pressures.

Codes of conduct are a tool that some companies utilize to burnish their CSR credentials (Doh and Guay, 2004). These are voluntary initiatives that companies agree to abide by. Since the 1990s, concerns over the downsides of globalization, particularly in the environmental and labor areas, have contributed to the growth of codes of conduct. Such codes are viewed by some NGOs and other stakeholders as a means to reign in the excesses of globalization. Codes may take the form of international agreements, or be sponsored by international organizations, the private sector, or nonprofit organizations. Rugmark, for example, is a partnership among development and human rights NGOs, companies exporting carpets from India, the Indo-German Export Promotion Council, and UNICEF India to devise and regulate a special label for hand-knotted carpets made without the use of child labor. Similar codes have been adopted by the apparel and other industries with regard to labor issues. Environment-related codes are also increasing in number and scope. The Forest Stewardship Council (FSC) monitors forestry practices and develops a global program combining public awareness, business collaboration, and green marketing. In the early 1990s, the World Wide Fund for Nature and several other major NGOs began exploring the possibility of setting up a voluntary global certification and accreditation system that could be used to verify whether or not wood products were harvested in a socially and environmentally sound manner. Proponents of forest certification sought to show that forests can be managed in a manner that is viable economically without compromising conservation. Through these means, the FSC convinced Home Depot, Wicke's, Lowe's, and Ikea to sell FSC-certified products. The FSC approach is somewhat unique because it

relies on institutionalized cooperation between NGOs and businesses, but environmentally oriented NGOs were pivotal in persuading retailers to apply pressure upstream on forestry companies. One of the most prominent codes of conduct is the United Nations Global Compact. The initiative supports businesses in their efforts to align their operations and strategies with 10 universally accepted principles in the areas of human rights, labor, environment, and anticorruption. To date, Global Compact counts over 5100 corporate participants and stakeholders from over 130 countries.

CONCLUSION

Managers' attention to CSR is unlikely to diminish any time soon. Globalization is increasing the web of linkages between companies, governments, consumers, media, NGOs, activists, and other groups around the world. It has become almost impossible for a company's actions in one corner of the world to go unnoticed elsewhere, particularly in richer countries where most MNCs—and their critics—are headquartered. Companies essentially have two choices in addressing CSR in their marketing and overall business strategies. The first is to react to crises as they develop, as Nike, Shell, and Nestlé initially did. The second and, in all likelihood, more successful option is to be proactive in anticipating which dimensions of their business operations are likely to generate controversy, developing responses in cooperation with critics, and integrating CSR into the company's business model.

family conglomerates

Daekwan Kim and S. Tamer Cavusgil

Family conglomerates are diversified family-owned businesses that are quite common in numerous emerging markets including India, Indonesia, Korea, Mexico, Philippines, Taiwan, Thailand, and Turkey, and many other countries (Kim, Kandemir and Cavusgil, 2003). They are important not only because of their role in their respective economies but also because of their potential as local business partners for multinational companies. Indeed, they are part of the economic landscape in most emerging markets. They are known as *Chaebols* in Korea, *Business Houses* in India, *Holding Companies* in Turkey, *Bumiputra* in Malaysia, and *Grupos* in Latin America. Family conglomerates are one of the most prevalent business structures with significant roles in these markets.

Owing to their scale and ownership nature, family conglomerates exhibited considerable resilience over the years with their ownership transcending several generations. Their strong presence in their respective economies implies much political clout in governmental relations, and recognition with customers. Interestingly, many family conglomerates seem to have successfully transformed themselves over time in order to sustain their competitiveness. Many are playing a crucial role in introducing new technologies and new products (see LAUNCH STRATEGIES; NEW-PRODUCT FORECASTING; SUCCESS FACTORS FOR NEW-PRODUCT DEVELOPMENT) to their respective economies.

Despite variations in organizational and national cultures (see SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE) surrounding them, these family conglomerates from different countries tend to evolve in much the same way. Quite often their origins and growth can be attributed to the special relationship they have with the government and the fast growing economy (Cavusgil, Kandemir and Kim, 2003). Market expansion such as diversification and internationalization are commonly adopted growth strategies. Ironically, family conglomerates both benefited from and had to adapt to their business environments.

Regarding the sustainability of family conglomerates in emerging markets, the optimistic view is that family influence within family conglomerates will remain strong due to accumulated wealth and stockholder power. Although the ownership of family conglomerates will be dispersed so that one family is less able to control a conglomerate, it is highly likely that a family as a strong collective owner can control a conglomerate utilizing the majority ownership gained through the cross investment. While some subsidiaries of family conglomerates in emerging markets are becoming publicly held, the founder's family still has significant influence and control on the management. Furthermore, as the second or third generation inherits the business, more family conglomerates hire professional managers, leaving family members a less direct role. This may help many family conglomerates solidify their role and presence in the respective markets.

The pessimists believe that family conglomerates will face pressure from government as well as domestic and international communities to reduce the number of core businesses in order to improve efficiency. Potential leadership vacuum could be another issue as the second or third generation takes the leadership role (Church, 1993). In addition, family conglomerates often reveal some degree of inefficiency due to the ownership structure (Khanna and Palepu, 1997; Schulze *et al.*, 2001). Allegiance to owners is a characteristic of family conglomerates (Drozdow and Carroll, 1997; Hayashibara, 1997) but not always good for their business efficiency. Therefore, it is possible that global pressures accentuate those inefficiencies and reduce family conglomerates to a few small businesses in the future.

Given their unique *competencies* (see CORE COMPETENCIES) in their respective economies, it is critical for multinational companies contemplating business in such markets to understand their role. As potential local *competitors* (see COMPETITOR ANALYSIS), family conglomerates will be formidable barriers for most multinational firms. At the same time, family conglomerates can take much of the hassle and difficulty out of entering and succeeding in emerging markets as collaborators and business partners. Indeed, family conglomerates have

2 family conglomerates

much to offer to multinational companies including a local business network, government contacts, consumer recognition, and established channels (see INTERNATIONAL MARKETING CHANNELS), among others. In turn, family conglomerates also stand to gain from the new business opportunities and know-how that multinational companies offer. By identifying the complementarities that family conglomerates offer, multinational companies can enjoy a more frictionless entry into emerging markets.

international franchising

Barry Quinn

THE FRANCHISE METHOD

Franchising has become a major driving force in the globalization of service businesses. Changes in the global trading environment such as the lifting of restrictive legislation and a greater homogeneity in buyer behavior have resulted in the further spread of franchising activity from the developed economies toward emerging markets in Asia, South America, and Europe. While traditionally associated with the fast food restaurant sector, franchising has been increasingly employed by companies in a range of sectors, including retailing, hotels, car hire, and industrial services. The term *franchising* has been used to describe a wide variety of business activities, but the contemporary franchise system commonly in use is known as *business format franchising*. There are clear advantages to adopting franchising as an international expansion vehicle and these are linked to the relatively low financial resources, lower risk, and the local knowledge offered by the franchisee.

INTERNATIONAL EXPANSION

The United States has traditionally been the world's single largest franchise market. However, franchising is now used widely by US and non-US companies as a strategy for growth in both developed economies and emerging markets. Market saturation has been cited as a key factor for franchisors in the United States, Canada, Western Europe, and Japan (Hoffman and Preble, 2004), and international expansion has generally occurred in markets geographically and *culturally close* (see MARKETING ASPECTS OF PSYCHIC DISTANCE; MARKETING ASPECTS OF CULTURAL DISTANCE) to the home market. For instance, Canada has been the preferred first destination for US franchisors (see, for instance, Walker and Etzel, 1973; Hackett, 1976; Walker and Cross, 1989). Evidence has been found to support the notion that franchising organizations only make international moves after reaching a significant level in their domestic operations (Walker, 1989;

Aydin and Kacker, 1990; Welch, 1990). An initial domestic presence is viewed as crucial for successful international expansion in that it aids the learning process that will be useful for later international expansion and that it creates a widespread network that, by itself, becomes a very tangible statement to potential franchisees, both local and foreign. However, an exception to this "rule" can be seen in the case of *retailing* companies (see INTERNATIONAL RETAILING). As service sector companies have developed franchise operations in their respective domestic markets, some retail companies only employ franchising as a strategy in international markets. In other words, franchising is adopted as an alternative strategy to the core operating presence developed within the domestic market (Quinn and Alexander, 2002).

EMERGING MARKET OPPORTUNITIES

The fundamentally expansionist nature of franchising would suggest that foreign markets will be perceived as providing favorable opportunities for growth, regardless of the level of development of the domestic market (see, for instance, Hackett, 1976; Hopkins, 1996). It is increasingly the case that franchisors are looking for opportunities in emerging markets (Welsh *et al.*, 2006) and franchising is being seen as one way for nations to grow their economies. This is the case in Asian markets such as China and Singapore (Choo *et al.*, 2007; Wang *et al.*, 2008). Such markets offer clear opportunities to franchisors, including high growth and demand for western products and services, urban populations, rising middle classes, and attractive legislative environments. Franchising is of great benefit to transitional economies, particularly the former communist economies of Eastern Europe where entrepreneurship and business development skills have been lacking (Welsh and Swerdlow, 1991; Anttonen *et al.*, 2005).

FORMS OF ACTIVITY

Master/area franchising, joint venture franchising, direct investment, and direct franchising are the major forms of franchising a firm can choose from when it decides to enter a foreign

market by the franchising route. In master/area franchising agreements, such as those favored by the Body Shop and the convenience store retailer 7-Eleven, the franchisor grants the master franchisee the right to subfranchise the franchisor's concept to others within an exclusive territory, creating a tripartite franchise relationship. For the franchisor, such arrangements mean that most of the work involved in expanding the operation in the foreign market is carried out by the foreign franchisee, thereby reducing the demands on the franchisor. However, control of the quality of the network's operations is crucial and difficult to maintain (Quinn and Doherty, 2000). The international franchisor will seek to maintain quality and standards through provision of adequate support, in terms of personnel and resources. There is the danger that franchisors may, in practice, underestimate the social, economic, and cultural differences of another country, particularly given the standardization ethos of franchising. This scenario becomes more likely as franchisors seek to avail of the growing opportunities in emerging markets that are generally culturally and geographically distant from the domestic market. Conflict can arise because of the considerable cultural distance (also see MARKETING ASPECTS OF CULTURAL DISTANCE) between the two parties, which increases their tendency to see the same situation in quite different ways. Thus, the strength of the relationship between the franchise partners is of paramount importance.

global sourcing strategy: an evolution

Masaaki Kotabe and Janet Y. Murray

As global competition has accelerated the speed of technological obsolescence for most products, companies can no longer survive simply by adopting a polycentric, country-by-country approach to international business. If companies with a new product do follow a country-by-country approach to enter foreign markets over time, a globally oriented competitor will likely overcome their initial competitive advantages by blanketing the world markets with similar products in a shorter time frame. Increasingly, how to source globally has become a critical strategic decision that is influenced by the capabilities needed to compete.

Without established sourcing plans, distribution, and service networks, it is extremely difficult to simultaneously exploit both emerging technology and potential markets worldwide. The increased pace of new product introduction and reduction in innovational lead time calls for more proactive management of locational and corporate resources on a global basis. In this article, we emphasize the choices companies make to perform activities either inside the firm or have those activities performed by others, anywhere in the world – which we call *global sourcing strategy*. Global sourcing strategy, therefore, refers to the management of (i) logistics (*see* DESIGNING A GLOBAL SUPPLY CHAIN: OPPORTUNITIES AND CHALLENGES) identifying which production units will serve which particular markets and how components will be supplied for production and (ii) the interfaces among R&D (*see* GLOBAL PRODUCT R&D), manufacturing/operations, and marketing (*see* GLOBAL MARKETING STRATEGY; MARKETING STRATEGY IMPLEMENTATION) on a global basis. Global sourcing strategy requires a close coordination among R&D, manufacturing/operations, and marketing activities across national boundaries (Kotabe, 1992).

GLOBAL SOURCING PHENOMENON

In a hypercompetitive and uncertain global business environment (*see* SOCIETY, CULTURE,

AND GLOBAL CONSUMER CULTURE) coupled with a more even distribution of supply capabilities worldwide, an increasing number of large and small firms either produce in lower-cost locations or outsource goods and services from lower-cost producers. To create a sustainable competitive advantage over their rivals, firms realize that it is imperative to continuously create and acquire capabilities. In addition to securing lower costs from global suppliers, firms increasingly outsource to gain access to suppliers' capabilities. Thus, the core driver of the latest form of global outsourcing (i.e., both onshore and offshore) is the heightened organizational and technological capacity of firms in decoupling and coordinating a network of remotely located external suppliers performing an intricate set of activities. Hence, how to source globally has become a critical strategic decision that is influenced by the capabilities needed to compete and help sustain a firm's competitive advantage.

Although firms have embraced global sourcing of goods and services, they have experienced mixed results. Gottfredson, Puryear, and Phillips (2005) found that about 50% of firms in their sample reported that their outsourcing programs fell short of expectations. Only 10% were highly satisfied with the cost savings, and 6% were highly satisfied with their offshore outsourcing overall. Other researchers (Leiblein, Reuer, and Dalsace, 2002) have even suggested that outsourcing may not be related to performance. Owing to the inconclusive performance outcomes, practitioners have started to question whether universally prescribing global outsourcing is the right way to go.

One plausible argument is that based on a "balance" perspective, there is an optimal degree of outsourcing. The outsourcing–performance relationship takes on an inverted-U shape, implying that as firms deviate further from their optimal degree of outsourcing, by either outsourcing (or insourcing) and offshoring (or onshoring) too much, their performance will suffer disproportionately. So, the key question for sourcing firms is how much global sourcing they should engage in, to achieve desirable performance.

Another plausible argument for the inconclusive sourcing performance findings is that

Table 1 Different sourcing strategies.

| <i>Ownership Aspect</i> | <i>Locational Aspect</i> | |
|------------------------------------|--------------------------|-------------------------|
| | <i>Domestic Sourcing</i> | <i>Foreign Sourcing</i> |
| Insourcing (intrafirm sourcing) | Onshore insourcing | Offshore insourcing |
| Outsourcing (contractual sourcing) | Onshore outsourcing | Offshore outsourcing |

desirable sourcing performance necessitates the sourcing strategy to achieve a strategic “fit” with the environment. Indeed, researchers have theorized that the appropriateness of a particular strategy is based on its “coalignment” or “fit” with environmental contingencies (Drazin and Van de Ven, 1985). Using contingency theory to examine the environment–strategy coalignment effect on performance, we believe that the environment and strategy interact in a dynamic process, and that a match between them would exert a positive impact on performance. Thus, firms that can adapt their global sourcing strategy effectively to both internal and external factors are likely to achieve better performance.

We focus on global sourcing as it adds many more complexities that do not apply to domestic sourcing strategy. In developing viable global sourcing strategies, firms must consider not only manufacturing and delivery costs, the costs of various resources, and exchange rate fluctuations, but also the availability of infrastructure (including transportation, communications, and energy), industrial and cultural environments, the ease of working with foreign host governments, and other factors. Furthermore, the complex nature of global sourcing strategy spawns many barriers to its successful execution. In particular, logistics, inventory management, distance, nationalism, and a lack of working knowledge about foreign business practices, are some of the major operational problems encountered by both United States and foreign multinational firms engaging in global sourcing.

Intuitive arguments, like “focusing on core competency” and “strategic sourcing,” are often made to legitimize the trends toward more global outsourcing. We first discuss the recent trends in global sourcing strategy. Then, we highlight the advantages and disadvantages of global sourcing, by providing a list of intuitive arguments for each. We then attempt to explain global sourcing

levels and how these relate to performance based on the two complementary perspectives of “balance” and “fit.” By synthesizing these two perspectives, we introduce existing theories of sourcing in this article.

Trends in global sourcing. The primary objective of global sourcing strategy is for the firm to exploit both its own and its suppliers’ competitive advantages and the comparative locational advantages of various countries in global competition. From a contractual point of view, the global sourcing of intermediate products such as components and services by firms takes place in two ways: (i) from the parents or their foreign subsidiaries on an “intrafirm” basis (i.e., insourcing) and (ii) from independent suppliers on a “contractual” basis (i.e., outsourcing). Similarly, from a locational point of view, multinational firms can procure goods and services either (i) domestically (i.e., onshoring) or (ii) from abroad (i.e., offshoring) (*see OFFSHORING AND MARKETING*). This leads to a matrix of possible choices presented in Table 1.

In the last two decades, we have witnessed three waves of global sourcing. The first wave, starting in the mid-1980s, was primarily focused on global sourcing of manufacturing activities. Therefore, research was conducted primarily on manufacturing firms. Large manufacturing firms increasingly set up their operations globally and began to use suppliers from many countries to exploit best-in-world sources (Quinn and Hilmer, 1994). Consequently, supply chains (*see SUPPLY CHAIN MANAGEMENT STRATEGY*) became more global and complex, with manufacturing firms sourcing from suppliers in many countries for raw materials, intermediate, and final products.

A second wave began to occur in the early 1990s, when firms started eliminating their information technology (IT) departments that had

Table 2 Recent waves in global sourcing.

| <i>Time Period</i> | <i>First Wave (since 1980s)</i> | <i>Second Wave (since Early 1990s)</i> | <i>Third Wave (since Early 2000s)</i> |
|--------------------|---|---|--|
| Type of activity | Manufacturing | Information technology | Business processes |
| Destinations | China, Central and Eastern Europe, Mexico, and others | India, Ireland, and others | India, Pakistan, South Africa, and others |
| Type of firms | Manufacturing | Manufacturing, banks, and others | Financial services, and services, more generally |
| Primary motives | Reduction in labor costs | Obtaining enough skilled programmers and cost reduction | Reduction in labor costs and round-the-clock service provision |

grown substantially. As IT itself had become commoditized and many firms had little interest in developing new information systems in-house, this IT outsourcing wave spawned the growth of specialist providers, such as EDS and Accenture. Global sourcing mostly involved labor-intensive and standardized programming activities, which could be easily sourced from low-cost locations like India. The rise of commercial applications for a wide range of firm activities, epitomized in enterprise resource planning systems, also implied that a marketplace had developed where independent suppliers could make competitive offerings.

A third wave, characterized as the offshoring movement, began in the early 2000s. We have witnessed the rise of business process outsourcing that extends beyond IT services to a range of other services related to accounting, human resource management, finance, sales, and after-sales services such as call centers. It is this third wave of business process outsourcing that has generated so much publicity. Many are concerned that foreign business processes suppliers may be moving up the knowledge chain more rapidly than expected by sourcing firms. Such knowledge transfer could, in the long run, undermine sourcing firms' ability to differentiate themselves from their foreign suppliers. Indeed, such hollowing-out concerns have previously been raised about outsourcing of manufacturing activities (Bettis, Bradley, and Hamel, 1992; Kotabe, 1998). We summarize our argument on these recent waves of global sourcing in Table 2.

GLOBAL SOURCING STRATEGY AND PERFORMANCE

It is widely suggested that global sourcing helps improve performance, particularly cost effectiveness (Trent and Monczka, 2003). Firms located in developed countries often find that labor costs are excessive, compared to the value that is added to their products. At the other extreme, some global sourcing may be driven by knowledge concerns. Some inputs, such as liquid-crystal displays and technical expertise, may be available only in certain other countries, thus making global sourcing not a choice but an imperative. As for the sourcing of many raw materials, domestic sourcing is not an option since many raw materials are unavailable domestically. Certain intermediate products tend to be sourced from locations near the source of raw materials. Another argument in favor of global sourcing is that it enables a firm to produce closer to its customer markets, thereby increasing access to its customers and obtaining critical market knowledge for product development (see GLOBAL PRODUCT DEVELOPMENT). For instance, Japanese manufacturing firms have, over time, replicated supply chains in North America and Europe to operate closer to these markets. Production and sourcing experience in these regions has also enabled them to improve their product offerings. Another reason to opt for global sourcing is that demand from various regions can be pooled, thus achieving maximum scale and bargaining power through single sourcing from a foreign supplier.

Table 3 Arguments for and against outsourcing.

| <i>The Case for Outsourcing</i> | <i>The Case Against Outsourcing</i> |
|---|---|
| <p>Strategic focus/reduction of assets Through outsourcing activities a firm can reduce its level of asset investment in manufacturing and related areas. Therefore, stock markets usually react favorably to outsourcing since more or less similar absolute profit levels can be obtained with lower fixed investments. Furthermore, outsourcing can help the management of a firm redirect its attention to its core competencies, instead of having to possess and update a wide range of competencies.</p> | <p>Interfaces/economies of scope Firms may benefit from internalizing production through scope economies. Manufacturing firms, in their outsourcing decisions, ought to reflect on the interfaces among R&D, manufacturing, and marketing. If there are important interfaces between activities, decoupling them into separate activities performed by different suppliers will generate less than optimal results.</p> |
| <p>Strategic flexibility Outsourcing may increase the firm's strategic flexibility. By using outside sources, it is much easier to switch from one supplier to another. If an external shock occurs, firms are able to react quickly by simply increasing or decreasing the volumes obtained from an external supplier. If the same item were produced in-house, the firm would not only incur high restructuring costs but also a much longer response time to external events.</p> | <p>Hollowing out Firms that outsource activities excessively are hollowing out their competitive base. Once activities have been outsourced, it tends to become difficult to differentiate a firm's products on the basis of these activities. Furthermore, a firm could lose bargaining power vis-à-vis its suppliers because its suppliers' capabilities may increase relative to those of the firm.</p> |
| <p>Avoiding bureaucratic costs Rising production costs are associated with internal production, due to a lack of a price mechanism and economic incentives inside a firm. As a consequence, firm efficiency will suffer.</p> | <p>Opportunistic behavior External suppliers may behave opportunistically as their incentive structure varies widely from that of the outsourcing firm. Opportunistic behavior allows a supplier to extract more rents from the relationship than it would normally do, for example, by supplying a lower than agreed-on product quality or withholding information on changes in production costs.</p> |
| <p>Relational rent In recent years, many researchers have argued that certain relationships with external suppliers can help create a competitive advantage. By outsourcing items on the basis of idiosyncratic and valuable relationships with suppliers, firms may be able to innovate, learn, and reduce transaction costs.</p> | <p>Rising transaction and coordination costs Excessive outsourcing may lead to high coordination costs. Firms are limited in their capacity to work with outside suppliers as partners and therefore, have to prioritize outside partners. If they simultaneously invested time and attention to all outside suppliers, this would induce very high coordination costs.</p> |

(continued overleaf)

Table 3 (Continued).

| <i>The Case for Outsourcing</i> | <i>The Case Against Outsourcing</i> |
|---------------------------------|--|
| | Limited learning and innovation A form of learning that is deemed especially important for attaining tacit knowledge is learning by doing. The supplier may acquire tacit knowledge by performing the activity; consequently, the outsourcing firm cannot appropriate all benefits. Appropriation of innovation and rents is always a problem in buyer–supplier relationships because both parties will try to obtain as many private benefits as possible. Furthermore, it may become more difficult to innovate, owing to the different incentives available and the subsequent lack of interfaces between firms. |

On the other hand, there are disadvantages associated with global sourcing. One major problem is “cultural differences” between buyers and their foreign suppliers (see BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS). Indeed, differences such as institutional and language problems may affect a relationship negatively. This raises another layer of issues related to the long-term sustainability of firms’ core competencies, particularly when firms begin to increase reliance on independent suppliers through outsourcing (for a more extensive discussion of outsourcing and core competencies, see Mol, 2007). There are two opposing views of the long-term implications of outsourcing. One school of thought argues that many successful companies have developed a dynamic organizational network through increasing cross-border joint ventures, subcontracting and licensing activities (Miles and Snow, 1986). This flexible network system, also known as *supply-chain alliances*, allows each participant to pursue its particular competence. Each network participant is complementing rather than competing against the other participants for the common goals. The other school of thought argues that while a firm may gain short-term advantages, there could also

be negative long-term consequences. As the firm becomes more reliant on its independent suppliers, it may not be able to keep abreast of constantly evolving design and engineering technologies without engaging in those developmental activities (Kotabe, 1998). Consequently, the firm encounters the inherent difficulty in sustaining its long-term competitive advantages. In other words, over time a firm’s technical expertise and capability surplus vis-à-vis its foreign suppliers may diminish to the point that its value added is limited, and it may become more like a trading company. Thus, based on the arguments for and against outsourcing, we need to synthesize our thinking on outsourcing and performance. A summary of these opposing arguments is presented in Table 3.

A “balance” perspective. A “balance” perspective offers insights on the sourcing strategy–performance relationship. The underlying argument of a “balance” perspective is that firms that outsource all of their activities run into a multitude of problems, such as a lack of innovation and bargaining power, and an inability to be distinct in the eyes of the customer. However, firms that only insource fail to use the powerful incentives supplied by markets, thus becoming bureaucratic and inefficient. Therefore, outsourcing some but not

all activities provides the best solution overall, and there is an optimal degree of outsourcing.

We believe a similar line of reasoning can apply to the degree of internationalization of sourcing (i.e., onshoring and offshoring) and how that affects performance. More specifically, there are advantages and disadvantages associated with global sourcing, as we highlighted above. As a firm does more offshoring (particularly, offshore outsourcing), the disadvantages become larger to the point where they severely impede performance. If firms do not use offshoring at all, they cannot enjoy any of the advantages of offshoring, such as having a wider supply base from which to choose. This line of reasoning is consistent with research in international business; it is, for instance, indirectly suggested by Dunning's (1993) treatment of international sourcing, and neoinstitutional economics traditions, particularly the transaction costs framework (Williamson, 1985).

Williamson (1985) distinguishes between production and transaction costs. Production costs refer to the costs of producing a good or a service, and transaction costs represent all the costs incurred as the product moves from one supply-chain partner to the next. When firms use offshore outsourcing by procuring from foreign suppliers, it may help reduce their production costs. In some instances, a local supplier's production costs may be lower than those of foreign suppliers, but this is often the exception and not the rule. Transaction costs, on the other hand, tend to be higher for such offshoring, as there are many types of institutional, cultural, and language barriers that must be overcome.

The cost of searching for supply sources abroad, whether internal or external sources, is somewhat higher than that for local supply sources. The cost of evaluating those foreign supply sources is much higher, as the evaluation costs are strongly related to the familiarity that decision makers have with the other party. Since firms are likely to be less familiar with foreign supply sources and decision makers may not be able to draw on their networks in helping them evaluate these sources, this induces substantial evaluation costs. Rangan (2000) uses this argument to explain why buying firms are much more likely to choose a domestic rather than a

foreign supplier, even when the physical distance between the buyer and each of these suppliers is the same.

We argue that offshoring is a balancing act between production and transaction costs. Firms need to find the proper balance between domestic and foreign supply sources (using onshoring and offshoring) if they wish to locate on the top of the curve and obtain the highest possible performance. They can achieve this by using foreign sources for part, but not all of their sourcing. Sourcing everything from abroad produces poor performance results because the disadvantages of offshoring, like the hollowing-out argument, become too large. Focusing all efforts on onshoring, however, is a serious form of myopia with equally disastrous effects on firm performance, primarily because the firm is not capitalizing on important opportunities to improve competitiveness. A graphic illustration of our argument is presented in Figure 1.

The balance perspective is therefore summarized as follows: Some activities are best outsourced globally while others ought to be integrated (from a performance perspective). A firm can enjoy optimal performance when it correctly outsources and integrates all activities. Similarly, the firm also needs to balance between onshoring and offshoring activities. This produces a pattern of an inverted U-shaped (negatively curvilinear) relationship between outsourcing and performance, with the top of the curve presenting the performance optimum.

A "fit" perspective. Despite the heightened publicity of global sourcing, many firms have been highly dissatisfied with their sourcing performance. The problem may be due to the fact that many researchers and practitioners have adopted a deterministic view in evaluating the global sourcing strategy-performance relationship, without exercising caution that such a view tends to overgeneralize the sourcing benefits.

Researchers often adopt the contingency approach in representing a "fit" perspective of the environment-strategy-performance relationship. Extant research has confirmed that some environmental factors indeed exerted moderating effects on the sourcing strategy-performance relationship. In the manufacturing

Figure 1 A curvilinear relationship between the degree of global outsourcing and firm performance.

context, Murray, Kotabe, and Wildt (1995) concluded that the financial performance advantage of global insourcing over global outsourcing of nonstandardized (i.e., major) components strengthened with increased product innovations, process innovations, and asset specificity.

Using foreign firms manufacturing in China as subjects of their study, Murray, Kotabe, and Zhou (2005) found that global outsourcing of major components (in the form strategic alliance-based sourcing) did not affect market performance. Instead, product innovativeness and technological uncertainty moderated such a relationship. Specifically, at low levels of product innovativeness/technological uncertainty, the use of strategic alliance-based sourcing of major components by the sourcing firm is positively related to market performance. However, at higher levels of product innovativeness/technological uncertainty, the sourcing-performance relationships become negative.

In refuting the popular arguments that insourcing or outsourcing will lead to superior performance, they found that sourcing strategy per se did not significantly affect performance. Instead, the sourcing strategy-performance relationship was driven by factors underlying sourcing strategy choice. They further cautioned against the universalistic normative implications for firms deciding on whether to insource or outsource their value-chain activities

and stressed the value of contingency-based theoretical approaches.

As discussed earlier, global sourcing of services did not take place until the second wave of global sourcing; therefore, extant literature on global sourcing of services (*see SERVICES MARKETING STRATEGY; SERVICE INNOVATION MANAGEMENT*) is limited when compared to that in manufactured goods. Murray and Kotabe 1999 found that similar to components and finished-goods sourcing, supplementary services were sourced globally, either by insourcing or outsourcing. The higher the asset specificity and the lower the transaction frequency of the supplementary services, the higher the global insourcing used. Finally, insourcing and offshoring of supplementary services were negatively related to the market performance of a service.

The fit perspective is therefore summarized as follows: There is a range of contingency factors (i.e., capital intensity, degree of service inseparability, market uncertainty, and transaction frequency) at the transaction-, firm-, and context-levels. These factors determine how much global outsourcing (both onshore and offshore) ought to take place from a performance perspective. To an extent, the contingency factors also explain how much global outsourcing actually takes place in practice. Fit is achieved when the actual global outsourcing level is in accordance with the level predicted

on the basis of the contingency factors. If a firm matches a global outsourcing decision to the relevant contingency factors, the resulting strategic fit helps achieve superior performance.

A “balanced-fit” perspective. The previous discussion raises two related questions. First, are these contradictory or rather complementary perspectives; if they are complementary, how do they complement each other? Second, how can we, taking into account these perspectives, explain the large increases in offshore and global outsourcing? We now seek to answer these two questions on the basis of the extant literature, specifically by drawing upon possible conceptual angles on global outsourcing.

To describe how the balance and fit perspectives complement each other, and to explain why over the past two decades or so we have witnessed the degree of global sourcing shifting toward more offshoring, we need to draw more directly upon key academic perspectives on global sourcing. We summarize 11 such perspectives in Table 4.

It is not in the scope of this article to describe each perspective in detail or to show how different perspectives are useful in predicting global outsourcing (for a more detailed description, see Mol, 2007). However, it is important to note that these perspectives operate at three different levels: the transaction, the firm, and the industry and institutional contexts. Taken together, they represent almost all the contingency factors that the academic literature has produced to date. Which of these perspectives matters most is to an extent determined by the empirical context in which outsourcing is investigated. Some of the perspectives have been more prominent than others in recent academic studies of outsourcing. Transaction-cost

economics and the resource-based view come to mind as examples, which may reflect their actual importance in practice.

This takes us back to the two questions. The first question can be answered by stating that exactly where the optimal point of outsourcing (balance) lies is determined by the scores on the contingency factors (fit). In terms of the second question, the optimal point in terms of how much a firm should engage in offshoring will shift over time. Over the past two decades or so, we have witnessed that the degree of global sourcing has shifted to the right in Figure 1, that is, toward more outsourcing and offshoring. This implies that changes in both the level of the contingency factors as well as their constitution (i.e., which variables matter and to what extent) have caused the increase in outsourcing and offshoring levels.

Taken together, the implication is that the balance in global outsourcing has shifted toward higher levels of outsourcing because of the need to fit global outsourcing levels to a set of changed circumstances. We suggest two major drivers of this change. First, IT, including the Internet, has greatly facilitated cross-border business-to-business transactions. Second, institutional changes, which lie at the heart of the rise of both China and India as supply destinations, have also facilitated cross-border trade and investment, both of which in turn lead to more global outsourcing. These conclusions provide different implications for managers.

CONCLUSIONS AND MANAGERIAL IMPLICATIONS

On the basis of these discussions, managers should rethink and redesign their global outsourcing activities. Many managers have a strong general sense for what constitutes a sound

Table 4 Perspectives on global outsourcing.

| | <i>Firm</i> | <i>Context</i> | <i>Transaction</i> |
|---------|-------------------------------------|-------------------------|----------------------------|
| Past | Resource-based view | Social networks | — |
| Present | Costly contracting | Industrial organization | Transaction-cost economics |
| | Microeconomics Core competencies | Institutional voids | Agency |
| Future | Real options Relations and learning | — | — |

outsourcing and offshoring policy. They realize that outsourcing and offshoring every activity may lead to disasters, just as much as they recognize that not all activities should be insourced.

There is currently a tendency in practice to describe performance problems related to outsourcing or offshoring as *implementation issues*. Managers often assume that their outsourcing or offshoring decision is the proper design choice, and tend to attribute its unsatisfactory performance to various implementation problems that occur when dealing with independent and overseas suppliers. We suggest that there are many more fundamental problems of outsourcing or offshoring that are unrelated to implementation problems. Rather, there are limits to outsourcing and offshoring, and many inputs of a firm should not be outsourced or offshored.

Managers are often not conscious of the fact that there is an optimal degree of outsourcing across their entire portfolio (Leiblein, Reuer, and Dalsace, 2002). Instead of using this portfolio level, they tend to see the good or the evil of outsourcing or offshoring particular items or activities in that suppliers are not well equipped, insufficient guarantees are built into contracts, or market circumstances change rapidly. Many firms do not conduct enough analysis before they jump into outsourcing or offshoring. This helps explain why, in practice, outsourcing or offshoring often looks like a bandwagoning process. Likewise, many academic approaches have centered on analyzing individual make-or-buy decisions.

However, the performance advantages of outsourcing or offshoring will only materialize when a firm has the organizational capacity to integrate outsourced and/or offshored items/activities into its operations. Furthermore, many companies make outsourcing or offshoring decisions by evaluating only a few options on the basis of their previous experience and by what their competitors are doing.

Managers are in need of guidelines as to where the optimal point lies for their particular business at a particular time. On the basis of the contingency approach using a "fit" perspective, we can suggest several indicators to help answer that question including asset specificity, uncertainty, firm competencies, industry trends, and

firm nationality and location. These moderating factors may help determine what is optimal for a particular firm at a particular time. Timing is crucial, as the optimal point will shift due to changes internal and external to the firm.

From a managerial perspective, developing a model that helps determine a firm's optimal degree of outsourcing or offshoring would be very useful. On the basis of this model, managers could prioritize their set of activities and outsource or offshore until they more or less reach optimality. As global sourcing is a dynamic process, competing firms may not accurately grasp the full benefit (and cost) of outsourcing or offshoring activities due to causal ambiguity. Simply bandwagoning on the first mover's current outsourcing or offshoring strategy offers no guarantee for improved performance. We suggest that tackling that challenge involves a broader behavioral understanding of how firms' outsourcing or offshoring trajectories change over time and within industries.

ACKNOWLEDGMENT

The authors acknowledge Michael J. Mol for his inputs on their previous research projects that help build the foundation of this article.

export performance

Luis Filipe Lages and Carlos M. P. Sousa

INTRODUCTION

The area of export performance is attracting both academic and managerial attention at an increasing pace. For more than three decades (1964–1998), work in the field was mostly concerned with understanding export-performance determinants. With the publication of a special issue on export performance measurement in the *Journal of International Marketing* in 1998, research in this topic received a new boost. Since then, several works have been presented to justify the existence of divergent findings in this field (Lages and Lages, 2004; Lages, Lages, and Lages, 2005; Diamantopoulos and Kakkos, 2007). Simultaneously, new works appeared arguing that export managers are not only proactive but also reactive to past results. As a consequence, research should also start considering export performance as an independent variable (Lages *et al.*, 2008b).

Today, after almost half a century of research in this theme, there is very little consensus on the key antecedents and outcomes of export performance as well as how export performance should be defined and measured (Sousa, 2004; Sousa, Martinez-Lopez, and Coelho, 2008). Not surprisingly, the current literature on export performance is fragmented, diverse, and inconsistent, hindering advancement in the field. It is fragmented because of numerous studies in the literature that are characterized for adopting a variety of analytical techniques and methodological approaches. It can be classified as diverse because of the different determinants and measures of export performance (*see* STRATEGIC EXPORT MARKETING–ACHIEVING SUCCESS IN A HARSH ENVIRONMENT). Finally, it is considered inconsistent because of the different and often contradicting findings that exist in the export-performance literature. Despite the critical importance of this theme both from public policy making and managerial perspectives, in our view, no consensus will exist in the literature until an established measure of

export performance is used. The purpose of this article is to provide an overview of the literature on export performance and a list of potential directions for future research.

SUBJECTIVE OR OBJECTIVE MEASURES?

Over the last five decades, a wide diversity of measures has been used in the exporting literature to assess performance (Diamantopoulos and Kakkos, 2007). A first choice to be made is between subjective and objective measures (*see* MARKETING METRICS). Supporters of subjective assessment argue that, although objective assessments in measuring actual export performance may be regarded as being “more trustworthy,” these measures raise different measurement problems. Obtaining accurate objective data on export performance is very hard because export managers are rarely willing to respond effectively to absolute values (Lages, Lages, and Lages, 2005). They will also argue that managers often disagree about which operational measures to use when setting targets because performance assessment is idiosyncratic to the type of firm and its environment, and some measures (e.g., profitability, sales, and ROI) raise comparability problems due to different accounting practices within strategic business units (SBUs) and across firms (Styles, 1998). Another major obstacle is that financial reports hardly ever make a distinction between the performance of domestic and export markets operations and even more seldom provide data on each export venture. As a consequence, objective metrics are rarely used because it is often impossible to establish a common definition of success/failure or fixed reference points across firms. On the other hand, by measuring perceived performance, researchers are able to capture the degree to which performance has matched the aspiration levels of the firm from one year to the next. The imaginary line separating success from failure will be determined by the level of expected performance and will serve as a useful starting point for future decision making. In sum, one may assume that an individual export venture will be successful when targets are met or exceeded and unsuccessful when it is below this *line* (Lages *et al.*, 2008b). Organizational learning theory posits that

2 export performance

performance achievement and satisfaction are crucial in triggering action, because managers are assumed to have a set performance goals to which performance outcomes are compared. Subjective measures of performance capture the degree to which performance matched these goals and aspiration levels of the firm, and seem to be directly amenable to comparison across firms. Managerial perceptions of the achievement of these exporting goals and satisfaction with the exporting activity may play a key role in the definition of firms' export activities (Lages *et al.*, 2008b). Future research should consider both objective and subjective dimensions of export performance (Katsikeas, Leonidou, and Morgan, 2000; Sousa, 2004).

AGGREGATED OR DESEGREGATED MEASURES?

Past research suggests that no single measure is adequate to assess export performance. The use of multiple measures and ways to measure export performance is necessary to fully realize the strengths of each indicator and to minimize the impact of their shortcomings (Sousa, 2004). No approach is perfect, and through a combination of several approaches one may increase the likelihood of having solid findings. Hence, for testing the robustness of export-performance findings, future research is strongly encouraged to use a combination of different approaches: total item aggregation, intermediary aggregation, and total desegregation approaches. While in the most aggregated approach, findings result in a loss of specific information, because the distinction among the independent items is lost, in the most disaggregated approach, it becomes harder to have an overall picture of export performance. As a consequence, the most common approach to assess export performance is an intermediary aggregation of various items into single performance measures (i.e., commonly denominated as *factors* or *constructs*) (Lages, Lages, and Lages, 2005). Although this combination of different measures into factors allows better contextualizing the complex performance construct (Katsikeas, Leonidou, and Morgan, 2000), this approach does not precisely capture the different dimensions of the performance phenomenon (Doyle and

Stern, 2006). In addition, some measures may correlate differently with other measures and different measures may have different weights depending on the context. For example, in the case of Western companies, rankings for specific performance variables have been created and profits became one of the most important performance measures. However, when managers focus on seeking outstanding profits, this may lead to poor results in other export performance metrics such as market share (Doyle and Stern, 2006). Likewise, when managers focus too much on sales volume, this might create problems on sales revenue, and, as a consequence, create image problems. As such, for future research, we strongly advocate the use of aggregation approaches in combination with single-performance items. This way, by using the most disaggregated approach, it will also be possible to treat each one of the items included in the model individually (Doyle and Stern, 2006).

STATIC OR DYNAMIC APPROACHES?

Although management research has been gradually moving from a static analysis to a more dynamic approach, research involving export performance predominantly follows a static approach. The literature on export performance rarely looks to change in terms of export performance and rarely implements a longitudinal research. This makes it difficult to implement dynamic models and limits efficacious measurement of performance (Katsikeas, Leonidou, and Morgan, 2000). Future longitudinal research allows a better analysis of the relationship between export performance and its determinants. Future research is strongly encouraged to build on organizational learning theory and strategic dynamics to better understand how export performance change occurs in foreign markets. Notwithstanding the significant amount of research conducted in exporting, a review of the literature indicates several shortcomings in this field.

SHORT- OR LONG-TERM ASSESSMENT?

Although the majority of the literature assumes that managers undertake a proactive and

long-term perspective of export performance, a number of studies have suggested that western firms are often reactive and short-term oriented (Madsen, 1998; Lages and Lages, 2004). Most studies do not specify the time period and assume that export performance is a long-term issue (Diamantopoulos and Kakkos, 2007). Among the rare exceptions that do so, while some prefer to use a more dynamic approach by trying to capture performance over a 12-month period (Morgan, Kaleka, and Katsikeas, 2004; Lages and Lages, 2004), others follow a more static approach by assessing export performance levels in a specific year (Lages, Lages, and Lages, 2005). To organize the literature in terms of export performance measurement, future research should make this aspect clear. Indeed, short-term analysis is a critical issue from a managerial perspective as many top managers wish to *see* short-term performance effects and do not give enough time to observe the effects of strategy in the long term. However, being overly focused on short-term goals may be risky for the long-term development of a firm's capabilities (Madsen, 1998). The importance of performance dimensions may also vary across stakeholder groups (e.g., investors, employees, and customers) and depend on whether the focus is on the short term or the long term (Sousa, 2004). A manager who focuses on the long term to increase the market share in a foreign market may not perceive export performance to be low when export sales or export profits are weak.

A DEPENDENT OR AN INDEPENDENT VARIABLE?

Interestingly, and despite the fact that the overwhelming majority of studies analyze performance as a dependent variable, it is uncertain which measures should be analyzed as causally dependent. Researchers tend to put export performance as a dependent variable even when the data collected on strategy and performance variables relate to the same period of time. However, managerial practice is expected to be dynamic. Past performance is highly likely to influence organizational change as managers tend to respond to performance feedback. However, to our knowledge, no study

has analyzed the impact of past performance on strategic change in international markets. Performance as an independent variable has been highly unexplored in an international marketing context (Lages and Montgomery, 2004; Lages *et al.*, 2008b are two exceptions). As the underlying aspects of export-marketing strategy are driven by managerial action, greater understanding of managerial learning from past export performance can provide marketing academics and practitioners with strategic insights into enhancing export performance (*see* CONCEPT OF CAUSALITY AND CONDITIONS FOR CAUSALITY).

THEORETICAL OR MANAGERIAL APPROACHES?

In the late 1990s, some attempts were made to develop comprehensive and psychometrically sound measures of export performance (Styles, 1998; Zou, Taylor, and Osland, 1998). Despite these attempts, a major concern remained that export-performance assessment tends to be misaligned with the managerial world (Madsen, 1998; Lages and Lages, 2004). Several reasons justify the need for a sound managerial evaluation of export performance. If one considers that exporting actions have an impact on the overall failures/successes of firms, it becomes necessary to have tools that allow managers to monitor export performance. Proper measures will provide decision makers with a reference to support the definition of future short- and long-term actions, such as the allocation of human and financial resources to specific export ventures. Export performance evaluation is equally important at the public-policy level. The benefits provided by the exporting activity encourage public policy makers to implement export assistance programs to enhance firms' global marketing strategies. As a consequence, a proper assessment of export-marketing strategy (Lages, Abrantes, and Lages, 2008a) and export performance will have an impact on any country's economic health (Lages and Montgomery, 2005).

During the last four years, some export measurement tools have been developed with greater managerial- and public-policy flavor. One of these tools is the STEP scale (Lages and

4 export performance

Lages, 2004), which addresses the short-time horizon frequently used by managers and public-policy makers to assess performance. Two other managerial tools – the APEV scale and the PERFEX scorecard (Lages, Lages, and Lages, 2005) – were specifically designed to be included in annual reports and to assess export performance both at the corporate and exporting venture levels. The APEV scale was inspired by the EXPEF measure (Zou, Taylor, and Osland, 1998). All these three scales (EXPEF, STEP, and APEV) are of a reflective nature and were developed using CONFIRMATORY FACTOR ANALYSIS. More recently, Diamantopoulos and Kakkos (2007) suggest that this field should also use formative indicators. As such, the authors propose the AEP index as a composite measure of managerial-subjective evaluations of export performance. This index enables the assessment and comparison of multiple export objectives, both within and between firms, by allowing the setting of the weights of the different indicators to be zero. From a managerial perspective, the major advantage of using performance metrics of a formative nature is that, in contrast to reflective aggregated measures, it becomes possible to identify which particular indicators the managers have in mind when assessing export performance.

DETERMINANTS OF EXPORT PERFORMANCE

Two broad theoretical approaches, the resource-based paradigm and the contingency paradigm, provide the basis for classifying the determinants of export performance into internal and external factors. Specifically, internal determinants are justified by resource-based theory, while external determinants are supported by contingency theory. Resource-based theory focuses on how sustained competitive advantage is generated by the unique bundle of resources at the core of the firm. The contingency paradigm suggests that environmental factors influence the firm's strategies and export performance (*see* STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY). The effects of various firm characteristics on export performance are dependent on the specific context of the firm. An extensive list

of studies has already identified key determinants of success in terms of the internal and external factors influencing successful export performance (Sousa, Martinez-Lopez, and Coelho, 2008). However, there is a lack of agreement on the domains and measurement of the determinants of export performance. This obstructs development of the theory on export performance, and makes it very difficult to compare the findings from different studies and literature. As a result, attempts should be made to develop clear conceptual domains and sound schemes to measure the variables. Nonetheless, after more than four decades of research on the analysis of the relationships among internal and external forces, export-marketing strategy and export performance, researchers now agree that export performance must be analyzed as a function of the fit between the firm's environment and the selected export-marketing strategy.

Despite the argument that control variables deserve as much attention and respect as do independent and dependent variables, most export performance studies fail to include them (Sousa, Martinez-Lopez, and Coelho, 2008). This disregard for the role of control variables is an issue of concern, and researchers are encouraged to account for these effects in future studies. In addition to the analysis of possible direct relationships (as undertaken by most investigators), future research is also encouraged to analyze the moderating effects of external forces and the indirect impact of environmental forces on export performance through their influence on strategy. The export-performance literature has reached a level of sophistication that researchers should be interested in detecting not only the main effects of independent variables but also their indirect and moderating effects.

UNIT OF ANALYSIS

There is no consensus in the literature regarding the level of performance assessment. Most export studies have looked at export performance at the firm level (Sousa, Martinez-Lopez, and Coelho, 2008). One possible explanation for this predilection by researchers could be the fact that respondents are more willing to disclose information at this broad level. The underlying

theoretical justification for firm-level studies is the theory on internalization (Rugman, 1980). This theory states that, in imperfect markets, firms should internalize the firm-specific advantages, both tangible and intangible, to extract maximum economic rent. Consequently, the study of export performance at the firm level has the benefit of capturing firm-specific advantages, which are derived not only from the development of a particular product but also from the total learning process of the firm. This allows examine the influence of potential determinants (e.g., overall firm strategy, organizational culture, organizational structure, R&D, etc.) that are not directly related to a specific venture. Other units that are commonly used are at the product level, strategic business-unit level, and product-market export venture level. Proponents of these three levels argue that it is unrealistic to expect that the same strategies can lead to the same results in all export products, SBUs, and product-market ventures. Naturally, the use of different levels of analysis will lead to different (and sometimes conflicting) insights on the topic.

FRAMES OF REFERENCE AND DIRECTIONS FOR FUTURE RESEARCH

Researchers use different frames of reference. In most cases, performance measurement tends to be self-driven. More recently, some works have explored performance assessment versus competitors (Morgan, Kaleka, and Katsikeas, 2004). Future research should consider the use of customer-, stakeholder-, and network-driven perspectives. In addition, employees within the same firm will hold different viewpoints of the same reality. As a consequence, the use of multiple informants within each firm will bring added value to assess this complex phenomenon (Sousa, 2004). With rare exceptions (Styles, 1998; Zou, Taylor, and Osland, 1998; Lages and Lages, 2004), most studies have used a single country or region as a frame of reference. The performance measures used in these studies often reflect the unique emphasis that different countries place on exporting (Zou, Taylor, and Osland, 1998). As a result, attempts should be made to validate scales across countries. However, considerable difficulties are likely to

be encountered in establishing equivalence and comparability of research in different studies. Researchers have to develop cross-cultural conceptualization and measurement that reflect true cultural differences among markets along the underlying construct under study. This can play an important part in advancing export-marketing theory by stimulating cross-cultural export-marketing studies that investigate specific similarities and differences among and between countries (Styles, 1998).

The United States is the most researched country in export-performance studies and despite a rise in the number of studies conducted outside the United States, there are still countries from certain parts of Asia, South and Central America, the Caribbean, and Africa that have received little or no attention from researchers (Sousa, Martinez-Lopez, and Coelho, 2008). Further research should consider the inclusion of such countries to investigate whether our current knowledge can be generalized to these countries, especially those from the developing world. Firms from developing countries are particularly interesting to study in future research because of their growing presence in an integrated global economy. In addition, most export performance studies involve samples drawn from manufacturing industries with relatively few studies investigating export performance of service firms. While there are some determinants and measures of export performance that apply to both manufacturing goods and services, it is likely that additional variables must be taken into account that relate to the specific characteristics of services firms when operating in the international arena (Sousa, Martinez-Lopez, and Coelho, 2008). Considering that services account today for around 20–30% of world trade, there is an increasing need for researchers to test whether traditional theories of GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES apply to the international marketing of services.

Taken together, the existing shortcomings in the export-performance literature create new research opportunities as they leave international marketing academics and practitioners without a clear understanding of the effects of

export performance as well as of the factors influencing it.

forces affecting global integration and global marketing

Kate Gillespie

Global integration is the state in which one national market (including a firm's home market) is significantly affected by other national markets. Because of global integration, international marketers cannot continue to successfully employ multiple single-market strategies but instead must adopt GLOBAL MARKETING STRATEGY that address multiple, if not all, national markets at the same time. Examples of such global strategies include global rollouts of new products, centralized production of standardized products, and global-theme advertising. In the last quarter of the twentieth century, several forces, some interrelated, resulted in greater global integration. These forces have been categorized in different ways but generally fall into five categories: technological, buyer behavior, competitive, cost, and regulatory. Each industry is affected differently by the forces of global integration, but virtually all industries are affected in some way by these forces.

Levitt (1983) first identified the emergence of global integration, focusing on the role of technology and the convergence of buyer behavior in what he termed the *globalization of markets*. Levitt argued that technological advancements, especially in the areas of communication, transport, and travel, made buyers in disparate lands aware of the same modern products. As a result, consumer wants and needs across countries had become irrevocably homogenized (see GLOBAL CONSUMERISM AND CONSUMPTION). This allows global marketers to sell more standardized products across different national markets (see STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY). Later authors have elaborated on both the role of technology and buyer behavior in global integration. For example, Yip (2003) notes that the speed at which new technologies become obsolete suggests that new products should be introduced quickly into all major markets at once to capture global-scale profits to offset shortened product life cycles (see STAGES OF THE PRODUCT LIFE CYCLE). He also argues

that the increase in per capita income in developing countries allows consumers in such countries to aspire to and afford products similar to those purchased in developed countries.

Competitive forces also drive global integration and, consequently, global marketing strategies. A new awareness of and need for foreign markets on the part of firms, combined with the convergence of buyer behavior across markets, has intensified global competition. On the one hand, many firms can more easily enter foreign markets without extensive product adaptation. On the other hand, foreign competitors can more easily enter the domestic market of those same firms. Thus global marketing has come to encompass strategic intelligence of global competitors. Firms increasingly study and respond to global competitors while acknowledging that their competitors are doing the same (see COMPETITOR ANALYSIS). Thus another argument for the global rollout of products is the need to preempt global competitors from stealing new product ideas introduced in a firm's home market before they are introduced in other markets. In addition, global competitive moves, such as attacking a competitor in their home market as retaliation for an attack on one's own domestic market, have become increasingly important to global marketers (Yip, 2003).

As global competition intensifies, price competition becomes increasingly important in most industries (see INTERNATIONAL PRICING OBJECTIVES AND STRATEGIES). As a result, cost considerations drive global integration as well. Standardizing products, or even partially standardizing products, across national markets allows firms to take advantage of production economies of scale. Centralized purchasing for needed inputs across national operations decreases operating costs in multinational firms. Global-theme advertising (see INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?) cuts promotion costs worldwide by standardizing portions of a multinational campaign while allowing certain national adaptations (Gillespie, Jeannet, and Hennessey, 2007).

Perhaps the most enabling driver of global integration has been the widespread market

2 forces affecting global integration and global marketing

liberalization that has encompassed both developed and developing countries in the last quarter of the twentieth century. Bilateral and multilateral trade agreements allow global marketers to capture cost savings from centralized production by allowing access to foreign markets via exports subject to no or low tariffs. Similarly national regulations discouraging foreign acquisition of local firms have increasingly disappeared, allowing foreign competitors to quickly buy market share in national markets. Transnational standards have emerged relating to many aspects of international marketing such as product specifications, rules relating to bribery, and legislation protecting brands (Gillespie, Krishna, and Jarvis, 2002). Without such regulatory liberalization and standardization, the other drivers of global integration would have far less impact on global marketing.

stages of market development

Peter Magnusson and Stanford A. Westjohn

A market's stage of development influences decisions relating to a firm's international marketing strategy, for example, entry mode, exporting, and GLOBAL SOURCING STRATEGY: AN EVOLUTION. However, categorizing a market depends on which classification is used. The classifications made by several notable international organizations are summarized in Table 1. The World Bank provides the strictest classification criteria. Countries are split into four categories based on gross national income (GNI) per capita, with the added provision that low- and middle-income economies are sometimes viewed as "developing," while high-income economies are considered "developed" (World Bank, 2008). The IMF identifies just two categories, "advanced," and "emerging and developing economies" (International Monetary Fund, 2008). The UN's UNCTAD arm uses the labels "developed," "economies in transition" (includes former Eastern European and Soviet-controlled countries), "developing," and "least developed countries" (UNCTAD, 2008). Although IMF's and UNCTAD's categories differ, both organizations maintain that strict criteria do not exist to determine a country's classification and that designations are for statistical convenience and do not necessarily express a judgment about a country's stage of development.

Stages of development need not be measured in purely economic terms, for example, GNI/GDP per capita, but may also include social and political development. For example, the United Nations Development Programme developed the Human Development Index (HDI). In addition to standard of living, captured by GDP per capita, the HDI includes life expectancy and access to knowledge, measured by literacy rates and education enrollment (UN Development Programme, 2008). The HDI reveals that some countries lag behind in terms of life expectancy and education despite having relatively high incomes. For example, the HDI rankings of South Africa and UAE are well behind their GDP/capita rankings. The Economist Intelligence Unit

(EIU) has also developed indices that measure market development. The "quality-of-life" index uses material well-being (GDP/capita), health, political stability and security, family life, community life, climate and geography, job security, political freedom, and gender equality (see CONSUMER WELL-BEING; FORCES AFFECTING GLOBAL INTEGRATION AND GLOBAL MARKETING) (The Economist, 2005). A second EIU measure, the Index of Democracy, focuses exclusively on a country's political progress toward democracy along five categories: electoral process and pluralism, civil liberties, functioning of government, political participation, and political culture (The Economist, 2008). The Index of Democracy reports a positive correlation between democracy and GDP/capita, and research suggests that the primary direction of causation is from democracy to income (Rigobon and Rodrik, 2005).

There are several methods for measuring market development but no universal standard exists. Traditionally, market development is based on economic development (i.e., GDP/capita), but more recent measures attempt to incorporate additional dimensions (i.e., social and political development). Notably, the popular "EMERGING MARKETS" label is largely absent from official categorizations, with the exception of IMF, which labels the "developing" category as "emerging and developing" markets. Furthermore, while economic growth indicates expanding commercial opportunities (see GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES; GLOBAL MARKETING STRATEGY), EIU found that economic growth is not related to a population's level of life satisfaction (The Economist, 2005). Given the inconsistent labeling of stages of development, researchers must carefully assess what is being measured when comparing more than one report or study. In making stand-alone evaluations of market development, researchers should select a classification scheme that best suits the question being asked.

services globalization

Haksin Chan

With diminishing trade barriers (*see* EMBARGOES AND SANCTIONS), emerging technologies (*see* DIGITAL MEDIUM AND GLOBAL MARKETING), and converging tastes (*see* GLOBAL CONSUMERISM AND CONSUMPTION), the era of globalization has arrived. Even “unlikely global candidates” in highly regulated service sectors have joined the ranks of global competitors (Johansson, 2002). However, global expansion (*see* MARKET ENTRY AND EXPANSION) poses major challenges for service operations, which are sensitive to sociocultural factors because of the prominent human elements. The adage “think globally, act locally” is especially applicable to services marketers.

THE INSEPARABILITY PROBLEM

Some services require a higher degree of local adaptation than others (*see* STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY). Lovelock and Yip’s (1996) categorization of services as people-processing (e.g., lodging), possession-processing (e.g., delivery), and information-based (e.g., insurance) highlights their different needs for adaptation. Typically, people-processing services (which involve customer participation throughout the service process) have the greatest need for localized operations. In general, services that are separable (i.e., services that can be performed away from the customer) enjoy more flexibility in their global expansion strategies than those that are inseparable (Erramilli and Rao, 1993). Since many services are characterized by inseparability (which precludes the less costly modes of entry), global expansion is usually a riskier choice for services marketers than for marketers of tangible goods. This may be an important reason for the *relatively* slow growth of global services (Grönroos, 1999). Nonetheless, innovative electronic- and self-service technologies should help circumvent the inseparability problem to some extent (*see* SERVICE INNOVATION MANAGEMENT).

THE VARIABILITY ISSUE

Because of the inherent variability of service performance, service failures are common occurrences (*see* SERVICES MARKETING STRATEGY). In general, consumers in Eastern, collectivist societies are more tolerant of service failures than their Western, individualist counterparts – this is due to longstanding cultural differences and contemporary economic conditions (Zhang, Beatty, and Walsh, 2008). However, the pattern is reversed when the nature of failure is “social” rather than “economic” (Chan and Wan, 2008). This reversal is consistent with the anecdotal evidence that Asian and Western airlines emphasize social (e.g., attentive flight attendants) and economic (e.g., convenient schedules) attributes, respectively. A similar pattern regarding social and economic attributes also manifests in cross-cultural consumer responses to post-failure recovery efforts (Hui and Au, 2001). Apparently, culture is an important consideration for the control of service quality and the design of service-recovery programs in global markets (*see* CROSS-CULTURAL PSYCHOLOGY OF CONSUMER BEHAVIOR).

THE PROTECTIONISM CONCERN

Although GATT/WTO negotiations have opened doors around the world, the pace of liberalization is slower for services than for manufactured goods. In particular, nontariff barriers for services are still pervasive (Javalgi and White, 2002). These barriers are formidable in sectors that involve strong vested interests at the national (e.g., banking) or professional (e.g., medical practice) level. In times of economic downturn, a resurgence of protectionism is a distinct possibility (Clark and Rajaratnam, 1999). On the consumer side, ethnocentrism (Shimp and Sharma, 1987), patriotism (Han, 1988), and animosity toward other nations (Klein, Ettenson, and Morris, 1998; *see* CONSUMER ANIMOSITY) are powerful forces that may hamper globalization. Note that the high visibility of many global service operations makes them easy targets in social and political crises. In 2008, Carrefour stores were the primary targets for boycott and protest when nationalistic Chinese expressed their outrage

at the French government. Arguably, the much-publicized fear of “McDonaldization” reflects a negative attitude toward the fast-food model as well as the Americana it represents.

THE NEED FOR RESEARCH

Practice has far outpaced research in global services, resulting in a significant knowledge gap. Until recently, the services marketing literature has devoted little attention to international issues, and the international marketing literature has seldom taken a service-oriented perspective. On a positive note, global services research is at the “takeoff stage” of its life cycle (Furrer and Sollberger, 2007). At the macro level, the continued trend of “servicization” should prompt refinement of existing global marketing theories (see GLOBAL MARKETING STRATEGY; GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES). At the micro level, research opportunities abound – for pinpointing culture-specific service quality dimensions, (dis)satisfaction responses, (see CUSTOMER SATISFACTION/DISSATISFACTION; CUSTOMER SATISFACTION) and recovery strategies.

gray markets

Kersi D. Antia

Gray marketing – the unauthorized distribution of genuine branded products – is a worldwide occurrence. The gray market for technology products alone is estimated to be worth US\$58 billion (KPMG-AGMA Gray Market Study, 2009). This is merely the tip of the iceberg, however, as gray marketed products span a wide spectrum, ranging from watches, pharmaceutical products, and running shoes, to commodity chemicals, automobiles, agricultural harvesters, and heavy earth moving equipment. It is widely acknowledged that any manufacturer with multinational ambitions or presence is more than likely to have faced gray marketing in some form or another (see MARKETING CHANNEL STRATEGY).

Accounts of gray marketing in the academic and trade press alike describe it as a single, monolithic phenomenon. The typical storyline is as follows – somewhere along the value chain (see MULTICHANNEL MARKETING), genuine product is “diverted” by authorized channel members to those outside the manufacturer-approved dealer network and ultimately to unwitting end-customers, who only realize the product is gray marketed when they need warranty support. The truth, however, is a little more subtle than that black and white characterization. In fact, gray markets occur under at least two strikingly contrasting circumstances, and are frequently participated in by knowledgeable, deal-prone businesses and end-customers that are well aware of the “gray market” status of the goods sold. Consider the two situations below:

In the first few days following the launch of the Apple iPhone in China (see LAUNCH STRATEGIES; MARKET ENTRY AND EXPANSION), less than 5000 units were sold (Hughes, 2008), a stark contrast to the heady reception the iPhone was accorded in its launch across several countries in Europe. The Chinese debacle was not altogether surprising, however, given that somewhere between 800 000 and 1.4 million iPhones are estimated to have been “unlocked” or able to run on networks other than Apple’s designated partners (Morrison,

2008) by way of gray market channels, “... a by-product of *pent-up demand* for a much-hyped device (see BRAND EQUITY; TRADEMARKS, PROPRIETARY MARKS, AND BRANDS) made by a company that places strict limits on where and how it is sold” (Burrows, 2008). Moreover, the gray marketed iPhones in China had additional features (wi-fi capabilities, stripped from the officially sold product to comply with Chinese government regulations) at a significantly cheaper price (see PRICING STRATEGY)! Not surprisingly, the diversion of Apple’s iconic product poses significant challenges for the company – US\$300-500 million in foregone revenues and profits for every 1 million iPhones diverted for “unlocking” (Elmer-De Witt, 2008).

Whereas the preceding instance of gray marketing is attributable to the strong cachet of the iPhone and the perception of its limited availability, (Inman *et al.*, 1997) that is, a high demand-lagging supply condition, gray markets also arise when demand-supply conditions are the obverse. Thanks to an economy in recession, nearly 34 000 businesses filed for bankruptcy in 2008, a 42% increase from just a year earlier (Hoffman, 2008). With resellers unable to sell products in these challenging economic conditions despite markdowns of up to 70%, a glut of liquidation-fueled gray market product was only to be expected (Crosby, 2009). Manufacturers found themselves in the uncomfortable position of having to compete with their own products being sold at steep discounts!

It should be clear from the preceding examples that gray market activity may be fueled by strong demand and scarce supply, as well as trenchant sales and a supply glut. Moreover, across both cases, customers are not the “surprised and confused victims” as often portrayed; rather, they are knowledgeable, deal-prone, and ever-resourceful parties that demand the best value for their spending dollar. Firms cognizant of these differences must apply the corrective strategies appropriate to each situation, rather than adopt a “one size fits all” approach to managing gray markets.

pricing and currency fluctuations in international marketing

Terry Clark, Daniel Rajaratnam, and David Campbell

As a topic of practical and academic concern, pricing is jointly claimed by the disciplines of finance as well as marketing. Both disciplines share an interest in how price relates to profit, and to competitive interaction. However, the interests of marketing go beyond this, extending to price as a component of value (*see* PRICING STRATEGY), as a communicator of quality, as a psychological cue (*see* HOW CONSUMERS RESPOND TO PRICE INFORMATION), and as a factor affecting brand equity (*see* PERCEPTION OF BRAND EQUITY).

In the international arena, a marketer's pricing concerns are complicated by two additional factors: (i) the existence of more than one currency and (ii) the existence of more than one culture (*see* BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS). We briefly explore the first of these.

The impact of multiple currencies on pricing decisions is clear when we consider the basic revenue and profit equations 1 and 2:

$$\text{Revenue} = \text{Price} \times \text{Quantity} \quad (1)$$

$$\text{Profit} = \text{Revenue} - \text{Costs} \quad (2)$$

In a pure export situation, in which costs are entirely in the currency of country A, and revenues entirely in that of country B, the profit equation becomes

$$P_A = (R_B \times FX_{AB}) - C_A \quad (3)$$

where

P_A = profit in country A's currency,
 R_B = revenue in country B's currency,
 C_A = costs in country A's currency, and
 FX_{AB} = exchange rate between currencies A and B.

Here, in Equation 3 the exporter's profit margin straddles the exchange rate, and fluctuates with it, regardless of how efficiently the firm is run, or what marketing strategy (*see* GLOBAL

MARKETING STRATEGY: PERSPECTIVES AND APPROACHES) is used.

Trade theory suggests that export (import) prices rise in response to trade imbalances. For example, suppose a world of just two trading nations A and B. Further suppose that nation A has a trade deficit with nation B. This implies strong selling pressure on nation A's currency, and a strong buying pressure on nation B's currency (i.e., importers in nation A must sell their own currency to buy nation B's currency to purchase nation B's goods). As this occurs, the price of nation A's currency goes down, and the price of nation B's increases (i.e., the exchange rate changes), resulting in a rise in the price of nation B's goods (from nation A's perspective), and a decrease in the price of nation A's goods (from nation B's perspective). The outcome is that nation A stops importing from nation B, and instead, begins to export to nation B, thus eliminating the trade deficit. Figure 1 illustrates this.

Here, the exporter from nation A sets price at time 1 in nation B at P_{B1} . This price determines the exporter's margin in nation A (M_{A1}). However, the exchange rate changes after time 1 (ΔFX_{AB1}). Trade theory (as explained above) suggests the exporter will adjust price in the export market each time the exchange rate changes, such that $M_{A1} = M_{A2} = M_{An}$. If this condition holds, trade imbalances will indeed be eliminated. However, trade theorists have noted the paradox that trade deficits persist, despite the solid logic of the argument outlined above. Why does this happen? Recent studies suggest that strategic actions of export marketing managers may, at least in part, explain the paradox.

What, for example, might we expect the firm to do when a currency appreciation/depreciation increases/decreases profit margins? A variety

Figure 1 Pricing and profit margins in the presence of exchange rate changes.

2 pricing and currency fluctuations in international marketing

of options are possible. For example, with a favorable exchange rate change, the firm could either maintain host-country prices and pocket increased margins, or else lower host country price and increase market share, without losing revenue. Then again, if the firm wished to lower price so as to increase market share, they may be unable to do so because their existing distribution system cannot increase the flow of goods to the export market.

On the other hand, the firm experiencing an unfavorable exchange rate change (i.e., their margins are diminished), might want to raise host-country prices to regain margins. However, to do so could put them at a competitive disadvantage, and concede market share to competitors. More likely, they would maintain price, so as not to lose market share, and thus be stuck with diminished margins. Then again, if the firm had previously invested in brand equity, they might be able to increase price (and regain margins), without substantially affecting market share.

The situation becomes more complex yet when firms from different countries compete against each other in third-country export markets. In such situations, one firm could be disadvantaged by currency fluctuations, while another could be advantaged, suggesting a host of complex competitive pricing situations.

In sum, pricing takes on some very interesting competitive twists when costs are in one currency, and revenues in another. These twists become highly complex, not to say game theoretic, when firms from different home countries find themselves competing in third-country markets.

countertrade

Aspy P. Palia

Many countries mandate, encourage, or permit use of countertrade – the linked trade obligations of two or more enterprises in two or more countries as stipulated in their import and export commitments. Exporters (*see* STRATEGIC EXPORT MARKETING–ACHIEVING SUCCESS IN A HARSH ENVIRONMENT) are often required to accept commodities/services in payment for the goods they sell overseas. If they accept these terms and conclude a countertrade agreement, they acquire a large inventory of countertraded commodities. Otherwise, they forego additional sales, MARKET SHARE, and entry (*see* MARKET ENTRY AND EXPANSION) into growing markets (*see* EMERGING MARKETS). Trading houses, multinational corporations (MNCs), and other countertrade specialists help dispose the surplus countertraded commodities. They specialize by services rendered, by product category, and by geographic region served (Palia, 1990).

The countertrade literature refers to a variety of transactions, which include barter, buybacks, clearing agreements, compensation, counterpurchase, evidence accounts, offsets, parallel trading, and switching (Aggarwal, 1989; Carter and Gagne, 1988; Cho, 1987; Choudhry, McGeady, and Stiff, 1989; Hennart, 1990; Huszagh and Huszagh, 1986; Khoury, 1984; Lecraw, 1989; Mirus and Yeung, 1986; Neale and Shipley, 1988; Okoroafo, 1988; Riesman, Aggarwal, and Fuh, 1989; Shipley and Neale, 1987). The US International Trade Commission recognizes five basic types of transactions: counterpurchase, compensation, offsets, barter, and switch (DeMarines, 1982).

Barter is the contractual, direct exchange of goods or services between two principals without the use of currencies. The contracting parties decide the values of the products/services to be exchanged. Barter agreements are often concluded between governments within one year. Otherwise, provisions are made to adjust the exchange ratio in response to world price fluctuations. Goods transfer is usually accomplished through a single contract. Barter transactions among governments are often accomplished through clearing agreements.

A clearing agreement between two nations specifies the goods to be exchanged, the exchange ratio, and the period during which the exchange is to be concluded. The exchange ratio is agreed to in advance and stipulated in the barter agreement. Accounts are maintained on the two-way flow of goods. At the end of the period (usually one year), any imbalance is corrected through hard-currency payments. If the clearing agreement is renewed/extended, imbalances in the flow of goods may be corrected through issuance of fresh credit.

Compensation agreements, referred to as *buyback* or *take-back*, entail the sale of plant, equipment, and/or technology. They involve the sale of a turnkey project/facility and specify that payment will be made via the plant output. Compensation transactions are generally of a higher value than other countertrade transactions. The product take-back period ranges from 5 to 20 years.

Exporters sometimes discover during the negotiations that in order for buyers in developing countries (DCs) and nonmarket economies (NMEs) to agree to the purchase contracts, the seller must agree to buy or market DC/NME products of usually less value than the original purchase contract. If the DC/NME offers products that are unrelated to the products sold by the exporter, the arrangement is referred to as *counterpurchase*. Counterpurchase transactions are relatively short term (one to five years). The counterpurchase requirement is agreed upon contractually. The seller must fulfill its contract within a specified period, failing which an agreed-upon penalty is imposed.

The offset agreement is used for defense-related contracts, commercial aircraft sales, and other priority items by the buyer government. The principals are a supplier (of defense-related equipment) in a developed country and a foreign government buyer. The supplier is required by the buyer government to assist in, or to arrange for, the marketing of products produced by firms located in the buyer country. Alternatively, the supplier must permit some portion of the exported product to be manufactured by producers in the buyer country.

Exporters that are unable to dispose the countertraded goods they receive, may decide to

sell them to a trading house specializing in switch trade. Switch may involve a series of complex transactions with sizable discounts before a hard-currency buyer is found. Switch-trader networks of firms and individuals offer ready markets for discounted countertraded products.

Exporters can take advantage (*see* COMPETITIVE ADVANTAGE: ITS SOURCES AND THE SEARCH FOR VALUE) of emerging opportunities in overseas markets if they are familiar with (i) the forms of countertrade practiced and (ii) the variety of trade, trade finance, consulting, international banking, marketing research, information, and other services provided by countertrade service organizations for specific products in specific markets (Palia, 1990).

emerging markets

Chris Styles and Ranjit Voola

The term *emerging markets* was coined in 1981, and has been used to describe countries that are on a trajectory to becoming developed or advanced markets. Emerging markets are characterized by a growing middle class, the introduction of economic reforms aimed at opening up the market (including greater transparency and accountability), and a steep (above average) economic growth rate. This is in addition to a mind-set of wanting to become active participants in a global economy (*see FORCES AFFECTING GLOBAL INTEGRATION AND GLOBAL MARKETING*).

There are a number of alternative operational definitions leading to some differences in the list of countries that are classified as emerging. For example, as of January 2009, the *MSCI* (Morgan Stanley Capital Investment) *Emerging Markets Index*, based on an analysis of equity markets, consisted of the following 23 market country indices: Argentina, Brazil, Chile, China, Colombia, Czech Republic, Egypt, Hungary, India, Indonesia, Israel, Korea, Malaysia, Mexico, Morocco, Peru, Philippines, Poland, Russia, South Africa, Taiwan, Thailand, and Turkey (MSCI Barra, 2009). The importance and rapid economic growth of these markets is demonstrated by the increase in weight of the emerging markets in the MSCI All Country World Index from 1% in 1998 to 12% in 2008. Further, between December 1998 and March 2008, the value of emerging equity markets had increased by 400% when compared to developed countries' growth of 44% over the same period (Briand and Fachinotti, 2008).

While there are many definitions for emerging markets, all of these tend to have three characteristics in common: (i) rapid economic growth; (ii) proactive adoption of market-based frameworks; and (iii) being in a transition phase between developing- and developed-country status.

Markets within the emerging category have been further classified on the basis of national income and progress on market infrastructure development. For example, the *FTSE* (Financial Times and the London Stock Exchange) index divides emerging markets into advanced

emerging markets (e.g., Brazil, South Korea), second emerging markets (e.g., India and Russia), and frontier markets (e.g., Bahrain and Sri Lanka). The overall methodology is based on economic size, wealth, quality of markets, and depth and breadth of the markets (FTSE, 2008).

The so-called BRIC countries (Brazil, Russia, India, and China) have been highlighted as exemplars of emerging markets. BRIC countries comprise 40% of the world population, a quarter of the earth's land coverage, and have a combined gross domestic product (GDP, purchasing power parity) in excess of 15 trillion US dollars. It is projected that by 2050 the BRIC economies have the potential to overtake the present richest countries in terms of economic wealth (Wilson and Purushothaman, 2003). A more detailed examination of India and China is instructive. India opened its economy in 1991 and its growth rate (GDP) was 9% in 2007, although this slowed to 5.3% in 2008 because of the global financial crisis. Similarly, China liberalized its economy in 1978 and had a growth rate of 13% in 2007, which again decreased to 6.8% in 2008, still considerably higher than that of developed markets (Zhixin, 2009). In addition, both countries have developed internal economic conditions and regulations that encourage local multinational companies (such as Tata in India and Lenovo in China) to actively compete with multinationals in advanced markets (*see GLOBAL MARKETING STRATEGY; GLOBAL PRODUCT R&D; GLOBAL SOURCING STRATEGY: AN EVOLUTION*). Both India and China also have a growing middle class – the World Bank estimates that by 2030 developing countries will account for 93% of the middle class globally, with China and India representing two-thirds of this growth (China 52%; India 12% increase) (Knowledge@Wharton, 2008).

The key challenges facing emerging markets include governance, political risk, rapid urbanization, a shortage of highly skilled labor, poor infrastructure, and more recently, the global economic slowdown that began in 2008. From a strategic point of view, the challenge for marketers is to identify viable segments with A FRAMEWORK FOR CREATING VALUE PROPOSITIONS relevant to local customers

2 emerging markets

(see MARKETING STRATEGY IMPLEMENTATION). Finding the correct price point (see INTERNATIONAL PRICING OBJECTIVES AND STRATEGIES) is also important to ensure affordability. Infrastructure, regulations, and local networks that can be difficult to break into are key strategic implementation issues (see MARKETING STRATEGY IMPLEMENTATION). The key is often to find a strong, well-connected local partner (see INTERNATIONAL MARKETING CHANNELS).

global sales management

Earl D. Honeycutt, Jr.

The sales-related activities that firms and organizations engage in when operating across borders in more than one country (see GLOBAL MARKETING STRATEGY). Sales executives and managers must master the challenges of working across national and cultural borders that exist in a global economy (see GLOBAL ACCOUNT MANAGEMENT: THE RATIONALE AND MOTIVATION). Global sales management can be divided into sales strategies (see SALES FORCE STRATEGY) and human resource practices.

Firms that sell their products overseas do so on a continuum from indirect partnerships to direct participation. On the basis of individual market situation, managers must decide upon the numbers, characteristics, and assignments of sales personnel (see INTERNATIONAL MARKETING CHANNELS). For example, companies entering the global market can find partners who provide existing salespersons or sales agents that understand the local marketplace, the local culture, and language (see SOCIETY, CULTURE, AND GLOBAL CONSUMER CULTURE) or salespersons from the home country can be assigned abroad. Firms are moving from multinational to transnational status. Transnational firms see a borderless global market with myriad locations to acquire natural resources, site production facilities, hire operations and marketing talent, offer high-quality products and services, and develop a global brand image. Multinational and transnational firms use three types of salespersons and sales managers: expatriates, local nationals, and third-country nationals. Each category of salesperson has advantages and disadvantages. Expatriates are sent from the country of the firm's headquarters and possess high company and product knowledge. However, they may be weak in the local culture and language. Home-country sales personnel understand local markets and cultures, but may be less dedicated to the firm and have less influence with headquarters. Third-country nationals originate from countries outside the work nation or firm country, speak several languages, and understand local markets and culture. Recently, as a result of cost

and expertise, companies are relying more on local managers to represent the global firm.

In the area of human resources, global sales managers must understand the lens through which they view the behavior of overseas sales representatives and sales managers. Managers who view sales situations and sales force behavior based upon how things are done in the home country, and do not understand local cultural practices, are likely to make serious "*faux pas*" or social blunders due to ethnocentrism (see CONSUMER ACCULTURATION). Poor decisions include selecting the wrong salesperson due to applicants not responding to questions/situations the way the sales manager expects; providing inappropriate training—it is easier to standardize technical knowledge and company information, but important to localize the selling process and competitive situation. Global sales personnel are also less likely to be motivated by money alone. For example, in Japan, the focus is on corporate culture and group interaction to motivate sales personnel. Lastly, evaluation of global sales personnel is influenced by the salesperson's level of individualism and perceptions of environmental control. To improve success, transnational firms select their global sales managers early and provide them with expertise and cultural intelligence training so that they can successfully manage workers from diverse backgrounds and cultures.

international trade intermediaries

Paul D. Ellis

International trade intermediaries (ITIs) are specialist intermediaries that are involved in the distribution of goods across national borders. ITIs are sometimes known as *trading companies*, *export management companies*, *sogo shosha*, or simply, *importer-exporters*. ITIs may be involved in many activities and perform a variety of services, but their core activity is the management of international trade. This service either involves an agency-brokerage role (selling on behalf of another) or a merchant-reselling (taking title to the goods traded) role (Casson, 1998). ITIs are ubiquitous in global markets and are one of the most enduring organizational entities in the history of international business. Historically, ITIs have played a prominent role in the development of international trade and marketing in many societies (Ellis, 2003a; Carlos and Nicholas, 1988).

Acting as agents, ITIs exist because manufacturers sometimes lack the ability or the incentive to engage in exporting directly (*see STRATEGIC EXPORT MARKETING—ACHIEVING SUCCESS IN A HARSH ENVIRONMENT*). By consolidating orders from multiple suppliers, building trade-supporting infrastructure, and developing logistical expertise, ITIs can improve the efficiency of distribution channels lowering the costs of exchange for others. In return, the intermediary typically charges a commission based on the cost of goods sold.

Manufacturers may hesitate to contract with independent intermediaries because of the threat of opportunism. This threat is central to the agency dilemma and arises because the manufacturer and intermediary possess different information about the exporting task. This imbalance or asymmetry may be exploited by the ITI. For example, to win a contract, the ITI may be tempted to conceal or misrepresent information regarding their abilities and resources. If the manufacturer as the principal cannot fully verify these claims in advance, they may suffer the consequences of adverse selection. Another potential problem, moral hazard, may arise after the contract has been signed when the principal

is unable to ensure that the ITI as the agent delivers the agreed-upon level of effort.

The hazards of relying on opportunistic intermediaries may render the agency relationship unattractive to manufacturers compelling them to pursue other modes of exchange, such as direct exporting. The circumstances under which manufacturers would prefer ITIs to in-house exporting can be predicted using transaction cost analysis, which describes the matching of exchange characteristics with particular exchange modes or governance structures (Anderson and Gatignon, 1986; Klein, Frazier, and Roth, 1990). For example, transaction cost analysis would predict a preference for direct or integrated channels (*see INTERNATIONAL MARKETING CHANNELS*) when traded products are complex and require a high level of after-sales service. In this type of exchange, the costs of performing intermediary functions in house are likely to be less than the combined ex ante costs of negotiating stringent contracts outlining the expected level of service and the ex post costs associated with monitoring and enforcing contractual obligations.

Acting as merchant resellers, ITIs create new markets for goods and services by developing exchanges between buyers and sellers located in different nations. In developing these links, the ITI may also transfer marketing skills to others in the channel. This may happen intentionally, as when an intermediary provides designs or materials for a new product, or unintentionally in the routine execution of the marketing function.

Although ITIs improve the efficiency of exchange and entrepreneurially create markets where none existed previously, their survival within cross-border channels of distribution is inherently impermanent. The information asymmetries that give ITIs their “edge” in a market tend to diminish over time undermining their position in the channel. As manufacturers gain experience dealing with foreign buyers, they may consider integrating intermediary functions and exporting directly to foreign markets. Indeed, by exceeding their client’s performance expectations, the intermediary may even hasten their own removal by signaling the benefits of going direct. This gives rise to the traders’ dilemma, which describes the increased risk of replacement attached to extreme levels of

2 international trade intermediaries

performance: Poor-performing intermediaries risk being replaced by other intermediaries, while high-performing intermediaries may be eliminated by upstream suppliers or downstream buyers keen to reap the benefits of more direct exchange modes (Ellis, 2005). In view of these threats to their survival, intermediaries continually seek out new opportunities to broker relationships. Consequently, the survival of the ITI is a function of (i) prolonging the inevitable decline of existing exchange relationships and (ii) replacing lost business with new relationships. When the addition of income from new business no longer matches the loss of income from exiting clients, the intermediary will have started down the path to organizational decline.

international negotiations

Bruce Money

Negotiating deal points is fundamental to any business transaction. Basic negotiation issues have come to be widely studied, such as whether one should anchor the transaction with a first offer, how negotiators respond to the pressures of a deadline, and decisions about how to make sensible concessions (*see* CONSUMER DECISION MAKING). Classic models of negotiation include the problem-solving approach (Graham, 1987), the relationships, parties' behaviors, and influencing conditions (RBC) model (Weiss, 1993), and the branching-chain model of multilateral negotiations (Pruitt, 1994).

It follows that conducting effective cross-national and/or cross-cultural negotiations is becoming increasingly important in today's global marketplace (*see* GLOBAL MARKETING STRATEGY). International business negotiations have their own uniqueness. Overcoming the obvious challenges of language differences and distant locations are just the beginning of effective negotiations with overseas clients. More subtle issues are numerous, and invoke questions such as the following

- What do people in other countries consider good negotiation?
- How can a negotiator be effective in a culture that is different from his or her or own? (*see* CROSS-CULTURAL PSYCHOLOGY OF CONSUMER BEHAVIOR)
- How do references to time, power, and other tactics differ in international contexts?
- What other global factors affect negotiation?

International negotiation presupposes an overlay of national culture and other cross-national factors on any of these models. According to Reynolds, Simintiras and Vlachou (2003), noncultural factors may include environmental and organizational factors (e.g., political or legal issues), individual negotiator characteristics (such as communication effectiveness or negotiation experience), factors related to the negotiation itself (such as norms and objectives), and negotiation outcomes (objective and subjective measures of success).

This framework loosely aligns that of Graham's (1987) model of personal *bargainer characteristics* (such as listening ability; combined with *situational factors* (e.g., physical setting,) to influence the *process* of negotiation (integrative vs. distributive; PERSUASION, to affect the *outcome* (satisfaction).

National culture probably looms the largest of the factors affecting international negotiation, the subject of dozens of studies (*see* BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS). For example, in Graham's model, culture would be one of the personal characteristics, and culture differences a situational factor. Two of the most prominent frameworks of national culture incorporated by most cross-national negotiation researchers are Hofstede's (2001) five dimensions of culture and the construct of context by Hall and Hall (1990). Briefly, Hofstede's dimensions of individualism/collectivism, power distance, uncertainty avoidance, masculinity, and Confucian dynamism, have been found to affect the negotiation process, depending on the dimension and negotiation phenomenon, for example, multilateral negotiations (Money, 1998).

Here mention should be made of the well-placed debate regarding the applicability of Hofstede measures at the individual behavior (Spector, Cooper, and Sparks, 2001), which has come to be known as the *ecological fallacy*. Values are more fine grained than index scores and need to be measured at the individual level, while recognizing the validity limitations of the Hofstede measures (Bearden, Money, and Nevins, 2006) (*see* VALIDITY IN EXPERIMENTATION).

The other cultural construct important to negotiation behavior is that of context, a measure of the implicit "code" in communication. Cultures are characterized as either high or low context (Hall and Hall, 1990) in their communication. In high-context cultures, the social and temporal setting of communications is key to understanding the intended meaning of messages, that is, the literal content of a message may be less important than the situation by which the message is conveyed. Low-context cultures, in contrast, do not depend as much on contextual factors in communication; rather the

words of a message are interpreted more literally. In other words, context is the amount of implicit communication “code” in a culture. Individuals from high-context cultures, such as those in Asia or Latin America, value face-saving, innuendo, and “between the lines” communication. More importantly, they are often misunderstood in negotiations by counterparts from low-context cultures such as the United States or Germany, where more explicit communications place emphasis on the message content (Weiss, 1993).

Finally, a recent review of international negotiation phenomena (Brett, 2007) suggests that other international factors may affect negotiation processes and outcomes (see GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES), for example, composition of multicultural teams in organizations internally, and externally, societal dilemmas, and government policies (see PRODUCT ETHNICITY) that may face and involve corporations and other organizations.

international product diffusion

Eden Yin

International product diffusion is becoming an increasingly important topic for both academics and industry practitioners as rapid globalization expedites market integration, which enables more goods and services to be diffused internationally. There is a growing literature on this topic. Most of these studies examine the differences in the diffusion process across nations and factors explaining the differences.

The general finding from these studies is that a nation's wealth, culture, social factors, and the time of its introduction are the critical determinants shaping a new product's diffusion process across countries. As for the wealth factor, even though an early study does not find it important in driving the cross-country takeoff (Tellis, Stremersch, and Yin, 2003), other studies prove otherwise (Chandrasekaran and Tellis, 2008). Moreover, a country's wealth is believed to affect the growth rate and duration of a new product across nations (Stremersch and Tellis, 2004). At the same time, income distribution and the level of international trade is proven to influence the penetration level, adoption rate, and speed of a product's diffusion (Talukdar, Sudhir, and Ainslie 2002). Such a conclusion also applies to the international diffusion of technology products subject to network externalities (Dekimpe, Parker, and Sarvary, 2000).

Research also finds culture, supposedly the most prominent factor in shaping international product diffusion, plays either a significant or partially significant role in affecting this process. Apparently, high context culture leads to faster adoption (Takada and Jain, 1991). At the same time, culture also shapes both growth rate and duration of a new product across countries even though to a lesser extent than economic wealth (Stremersch and Tellis, 2004). Moreover, cultural traits such as higher need for achievement, higher level of collectivism, industriousness, and lower uncertainty avoidance are associated with a quicker takeoff (Chandrasekaran and Tellis, 2008), or explain only intercountry differences in time-to-takeoff partially (Tellis, Stremersch, and Yin, 2003).

As for social factors, a number of studies indicate that the percentage of women in labor force (Talukdar, Sudhir, and Ainslie, 2002, Gatignon, Eliashberg, and Robertson, 1989), mobility (Gatignon, Eliashberg, and Robertson, 1989), cosmopolitanism or level of urbanization (Gatignon, Eliashberg, and Robertson, 1989, Talukdar, Sudhir, and Ainslie, 2002), heterogeneity of the country's social system (Dekimpe, Parker, and Sarvary, 2000), type of communication (Takada and Jain, 1991, Putsis *et al.*, 1997), and so on significantly affect the process of international product diffusion. In particular, Takada and Jain (1991) conclude that the rate of adoption in countries characterized by homophilous communication is faster than that in countries characterized by heterophilous communication, while Putsis *et al.* (1997) suggest that focusing on the most gregarious countries will maximize adoption in subsequent countries.

Studies also identify other sets of factors that influence the diffusion process of products in international markets. For instance, the time of introduction and therefore the introductory lag affect the penetration level, adoption rate, and speed of product diffusion (Talukdar, Sudhir, and Ainslie, 2002). The later a product is introduced in a market, the faster will be the rate of adoption (Takada and Jain, 1991). With regard to the product takeoff, besides culture and wealth, product class, product vintage, and prior takeoff are also important drivers for it to occur (Chandrasekaran and Tellis, 2008). In the context of technology products, installed base and international experience with this technology also affect the diffusion process (Dekimpe, Parker, and Sarvary, 2000). The direct managerial implication from these studies is whether a firm should adopt a sprinkler, that is, simultaneous introduction, or waterfall strategies, that is, sequential introduction, when they launch their new product globally. Some researchers support the former (Ohmae, 1985), while others endorse the latter (Putsis *et al.*, 1997, Tellis, Stremersch, and Yin, 2003; Stremersch and Tellis, 2004). In fact, the tradeoff between a waterfall and sprinkler strategy reduces to a tradeoff between sales maximization, for example, sprinkler, and risk minimization, for example, waterfall.

marketing aspects of psychic distance

Jody Evans

The term *psychic distance* was first introduced by Beckerman (1956) in the concluding paragraph of his study on the distribution of international trade. It is the work done at the Uppsala University during the 1970s, however, that is credited with developing and popularizing the construct. Johanson and Wiedersheim-Paul (1975, p. 308) defined *psychic distance* as those “factors preventing or disturbing flows of information between firm and market.” O’Grady and Lane (1996) redefined *psychic distance* as “... a firm’s degree of uncertainty about a foreign market resulting from cultural differences and other business difficulties that present barriers to learning about the market and operating there” (O’Grady and Lane, 1996, p. 330). More recently, Evans and Mavondo (2002, p. 517) focused on the aspect of perception and defined *psychic distance* as “the distance between the home market and a foreign market, resulting from the perception of both cultural and business differences.”

While the definition has evolved over time, there is a general consensus that psychic distance relates to differences between the home and foreign market that impede learning and foster uncertainty. There is also significant overlap in the lists of constituent elements. These include differences in culture, language, religion, education, legislation, politics, economic conditions, market structure, and business practices. The primary source of current debate relates to the manner in which psychic distance is operationalized. There are four debatable issues: (i) perceived versus objective measures; (ii) national versus individual measures; (iii) cultural distance (see MARKETING ASPECTS OF CULTURAL DISTANCE) versus psychic distance, and (iv) the relative importance of contributing factors (Dow and Karunaratna, 2006).

In terms of outcomes, psychic distance has been linked to foreign market selection, entry mode (see MARKET ENTRY AND EXPANSION), the standardization/adaptation of marketing strategies (see STANDARDIZATION/ADAPTATION OF INTERNATIONAL

MARKETING STRATEGY), and firm performance (see EXPORT PERFORMANCE). Psychic distance has traditionally been associated with the internationalization process. In particular, the underlying premise of the Uppsala model is that the internationalization of a firm is an incremental process where firms initially enter markets that are psychically similar and successively expand into more distant foreign markets. This positive association between psychic distance and the sequence of market entry has received limited support. There are suggestions that in the dynamic global marketplace, other factors may play a more important role in determining market selection or may confound the nature of the psychic distance–internationalization process relationship (Ellis, 2008).

Psychic distance plays a critical role in both entry-mode (see MARKET ENTRY AND EXPANSION) and marketing-strategy decisions (see STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY). The greater the psychic distance between the home market and a foreign market, the more likely a firm is to adopt an entry mode that requires less financial commitment and lower levels of sole control. This can be attributed to the fact that firms will perceive greater risk in markets that are psychically distant and, consequently, will seek to minimize their financial exposure. In terms of marketing strategy, the feasibility of a predominantly standardized strategy is driven by market similarity. Correspondingly, psychic distance is associated with adaptation of marketing strategy where firms may choose (discretionary) to adapt their strategy or are forced (obligatory) to respond to market differences.

A paradoxical relationship is said to exist in regard to psychic distance and firm performance (see EXPORT PERFORMANCE). O’Grady and Lane (1996) suggest that an assumption of similarity prevents executives from noticing subtle, but important, differences in psychically close markets, which is strongly associated with poor organizational performance. Evans and Mavondo (2002) contend that when firms enter psychically distant markets the increased sense of risk and uncertainty will elicit a strong desire to learn more about the market. This knowledge

2 marketing aspects of psychic distance

will enhance the firm's strategic decisions and, consequently, its performance.

marketing aspects of cultural distance

Carlos M. P. Sousa

There is a general consensus in the literature that when firms decide to enter foreign markets, they must adjust to a different cultural environment and be prepared for challenges, such as differences in language, lifestyles, cultural standards, consumer preferences, and purchasing power, among others (see GLOBAL MARKETING STRATEGY; CROSS-CULTURAL PSYCHOLOGY OF CONSUMER BEHAVIOR; STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY; BASE OF THE PYRAMID MARKETS: CULTURE INSIGHTS AND MARKETING IMPLICATIONS). To assess these differences between countries, a new body of literature has emerged around the concept of cultural distance, which has been used to measure the scope and scale of these differences. The assumption is that cultural differences between the home and the foreign markets create a distance, which, in turn, influences the activity of the firm in the international arena. As a result, few concepts in the international-marketing literature have gained broader attention than “cultural distance.” This concept has been identified as a key variable in explaining the behavior of firms in a vast array of areas including entry-mode choice, foreign-market selection, level of control (see MARKET ENTRY AND EXPANSION), international-marketing strategies (see GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES), and performance (see EXPORT PERFORMANCE). Mixed empirical results, however, have been found in the literature regarding the importance of this construct. Whereas some studies have found cultural distance to significantly influence the activity of the firm in the international arena (Barkema and Vermeulen, 1997), other studies have found no significant or clear relationship (Mitra and Golder, 2002).

Various reasons have been proposed to explain these inconclusive results. On the one hand, some scholars have argued that the preferences and tastes of consumers in different countries are converging to a global norm (Levitt, 1983), and hence the effect of cultural distance is likely to

dilute progressively. The notion that national cultures are converging appears to be plausible considering the emergence of the Internet, greater ease of information flow, and more frequent/easier international travel. However, this argument is disputed by Barkema and Vermeulen (1997), who use data spanning almost three decades (1966–1994) in their study, and find that the effect of cultural distance does not decrease over time, that is, that cultural values and distances remain stable. This may be due to the fact that such changes concern convergences in superficial appearances of culture (i.e., symbols, heroes, and rituals) and that they do not necessarily signal a convergence in the values embedded in national cultures (Hofstede, 2006).

The inconsistencies could also be attributed to the difficulty that exists in the conceptualization and operationalization of the cultural-distance construct. For instance, as Sousa and Bradley (2006, 2008) note, many authors have used cultural distance and *psychic distance* (see MARKETING ASPECTS OF PSYCHIC DISTANCE) interchangeably with no clear distinction between them, a contamination that has been disputed by these authors and which may undermine the validity of the research (see RESEARCH RELIABILITY AND VALIDITY). *Cultural distance* has been defined as the degree to which cultural values in one country are different from those in another country (Sousa and Bradley, 2006). Accordingly, it should be used to assess differences in national culture. Several frameworks have been advanced and used in the measurement of the extent to which different cultures are similar or different, such as that of Kluckhohn and Strodtbeck (1961) and Ronen and Shenkar (1985). However, the most widely used framework is that of Hofstede's (1980) cultural dimensions. To arrive at a measure of cultural distance, Kogut and Singh (1988) were the first to combine Hofstede's dimensions into one aggregate measure of cultural distance among countries, and many studies have subsequently used this formula or an adapted version, as a measure of cultural distance. However, while a tangible and convenient tool, the Kogut and Singh index has been liable to the same criticism as that leveled against Hofstede's value

2 marketing aspects of cultural distance

dimensions, for example, nonexhaustiveness, outdated data, assumptions about the linearity, additivity, and normal distributions of scores (Shenkar, 2001). As a result, there has been an increasing call in the literature to develop new measures (see VALIDITY AND RELIABILITY) to operationalize cultural distance as it may be unrealistic to expect that a single measure can fully discern the underlying differences across countries (Tihanyi, Griffith, and Russell, 2005). Some recent studies may offer some interesting alternatives to measure cultural distance (Schwartz, 1994) and should, therefore, be explored in future studies.

consumer animosity

Jill Gabrielle Klein

Our world is fraught with international conflict that leads people to feel angry at other countries. This anger is sometimes manifested in the decisions consumers make about what to buy. Consumer decisions, in other words, can depend on more than just the material value of a product. They can depend upon how people feel about the country where the product was made.

The animosity model of foreign product purchase demonstrates that animosity, defined as the remnants of antipathy toward another country due to past military, political, or economic conflicts, affects the buying of foreign goods (Figure 1). Numerous studies have been conducted on consumer animosity since the introduction of the model to the literature in 1998. The context of the first study was Nanjing, China, a city that was the site of the horrific slaughter of approximately 300,000 civilians by the Japanese in December 1937 and January 1938. Survey research demonstrated that Nanjing consumers who were still angry with Japan because of the massacre were less willing to buy Japanese goods, and actually owned fewer Japanese electronic and durable products (Klein, Ettenson, and Morris, 1998). Interestingly, angry consumers did not denigrate the *quality* of Japanese products. They acknowledged the good workmanship, reliability, and technological advancement of Japanese products, but they still refused to buy them.

This fundamental premise of the animosity model – that effects of animosity on buying are direct and independent of product quality judgments – diverges not only from traditional country-of-origin research (see “COUNTRY OF ORIGIN” AS BRAND ELEMENT) but also from most behavioral frameworks in marketing which assume a primary relationship between consumers’ product judgments and their purchase behavior (e.g., Green and Srinivasan, 1990). In the case of consumer animosity, anger can lead consumers to eschew a country’s goods in spite of positive product perceptions.

Subsequent demonstrations of the effects of consumer animosity have shown wide generality

of the model across the globe (see Riefler and Diamantopoulos, 2007). For example, Dutch consumers who are still angry at Germany because of World War II, are less likely to purchase German products (Nijssen and Douglas 2004). Japanese consumers who remain angry with the United States for dropping the atomic bomb on Hiroshima and Nagasaki still shun American products (Klein and DeBroux, 2001). Animosity can even affect how consumers feel about buying products from within their own country. Southerners in the United States whose anger still lingers from the Civil War prefer to purchase products produced in the south rather than the north (Shimp, Dunn, and Klein, 2004).

The animosity model also includes the construct of consumer ethnocentrism which is the tendency to believe that it is inappropriate or even immoral to purchase foreign products because doing so is harmful to the domestic economy (Shimp and Sharma, 1987). Previous studies have found that those high on the CETSCALE, which measures consumer ethnocentrism, are less willing to purchase foreign products, and view foreign products as lower in quality than domestic products (Netemeyer, Durvasula, and Lichtenstein, 1991).

Thus, while consumer ethnocentrism is related to *both* product judgments and purchase intentions, animosity affects consumers’ purchase decisions *independently* of product judgments. A further distinction between the constructs is that animosity is comprised of consumer feelings toward a specific country, whereas consumer ethnocentrism concerns attitudes toward buying goods from *all* foreign countries. While some consumers may find it perfectly acceptable to buy foreign products from a variety of countries, they may refuse to buy a product from a specific nation toward which they feel enmity.

International conflict has many dire consequences, as we see on our television screens on a daily basis. From a consumer behavior standpoint, these tensions have the additional effect that consumers may avoid the products of the offending country. And just as the conflicts of decades ago still have an impact on current consumer choices, the conflicts of today may will

Figure 1 The animosity model of foreign product purchase.

cast their shadow on consumption decisions for decades to come.

consumer affinity construct

Adamantios Diamantopoulos and Eva M. Oberecker

Sentiments toward foreign countries as captured by constructs such as CONSUMER ANIMOSITY, consumer ethnocentrism, consumer cosmopolitanism¹ or xenophilia,² have potential power in explaining consumption behavior toward foreign products (*see* PRODUCT ETHNICITY) and are thus of importance to international marketers. The consumer affinity construct specifically captures *favorable* sentiments toward a *specific* foreign country, which “affect[s] behavioral consequences (i.e., conations), such as intentions to consume products, brands, and services from the affinity country” (Oberecker, Riefler, and Diamantopoulos, 2008, p. 25).

The conceptual core of the affinity construct is *positive affect*³ and drawing from social identity theory (Tajfel, 1982), affinity builds on the distinction between in- and out-groups and assumes that an out-group can potentially be included into one’s in-group(s). In a country context, this means that due to affinity for a particular foreign country, the latter foreign country may supplement the in-group (i.e., the home country). Formally, *consumer affinity* is defined as “a feeling of liking, sympathy, and even attachment toward a specific foreign country that has become an in-group as a result of the consumer’s direct personal experience and/or normative exposure and that positively affects the consumer’s decision-making associated with products and services originating from the affinity country” (Oberecker, Riefler, and Diamantopoulos, 2008, p. 26).

Riefler and Diamantopoulos (2007) and Oberecker, Riefler, and Diamantopoulos (2008) independently established that consumers indeed have affinities for certain countries. Addressing the bases of affinities, seven categories of affinity drivers that capture direct (i.e., so-called micro-drivers) and/or indirect (i.e., macro-drivers) experiences with a country can be identified. Microdrivers include individual interactions with the country like *traveling* to, having *contact* with (e.g., through friends or relatives), or long-term *stays* in the focal country

while, macrodrivers capture a country’s *lifestyle*, *scenery*, *culture*, and *politics and economics*.

Regarding the consumption-related consequences of consumer affinity, the insights gained from Oberecker, Riefler, and Diamantopoulos (2008) do not reveal a consistent positive impact of affinity on product judgment; however, findings point to a heightened willingness of particular consumer segments to buy products from the affinity country. This heightened willingness is largely the consequence of a desire to consume products both as a means for remaining connected to the affinity country and as a means for lowering perceived risk. Such segments (*see* MARKET SEGMENTATION AND TARGETING) might be also willing to pay price premiums for products from the focal country.

Consumer affinity can be differentiated from the constructs of xenophilia, internationalism,⁴ and consumer animosity (for a detailed review, see Oberecker, Riefler, and Diamantopoulos, 2008). Rather than addressing favorable ATTITUDES toward foreign countries *in general* (like xenophilia and internationalism do), consumer affinity specifically refers to a positive, *country-specific* affect. Moreover, the consumer animosity construct, which captures negative sentiments toward a specific foreign country is not the polar opposite of consumer affinity, because, according to Oberecker, Riefler, and Diamantopoulos (2008), the key drivers of consumer affinity – which are a country’s lifestyle and scenery as well as personal experiences through stays abroad – are different from Klein, Ettenson, and Morris’s (1998) sources of consumer animosity (i.e., military, political, and economical events). Additionally, Jaffe and Nebenzahl (2006) expect that consumers rarely experience feelings of affinity and animosity for a specific country at the same time. Consumer affinity can be further distinguished from the country image construct⁵ (*see* “COUNTRY OF ORIGIN” AS BRAND ELEMENT). While consumer affinity is conceptualized as being purely *affective* in nature and relating to a *specific* country, the country image construct comprises positive, negative, and neutral images for a variety of countries, the latter images being largely based on beliefs (i.e., cognitions). Furthermore, product country image⁶ and consumer affinity are distinct

2 consumer affinity construct

constructs. The former construct specifically addresses *product-related* characteristics like the product quality, whereas consumer affinity only reflects positive feelings toward a specific *country*.

Policy makers and marketing managers are advised to consider the consumer affinity segment when designing their marketing strategies (see MARKETING STRATEGY). They can undertake efforts in inducing such positive feelings (e.g., by attracting foreign students, tourists, or professionals to their country, or by launching commercials that highlight emotional sentiments toward a country) and thus leverage the heightened willingness to consume products and pay price premiums for products from the affinity country. At the same time, the consumer affinity segment could be a potential target segment in ethnocentric markets, where consumer preferences are likely to be dominated by domestic products.

ENDNOTES

¹ A *cosmopolitan consumer* is defined as “an open-minded individual, whose consumption orientation transcends any particular culture, locality, or community and who appreciates diversity including trying products and services from a variety of countries” (Riefler and Diamantopoulos, 2008).

² *Xenophilia* is defined as “love of strangers and foreigners and an implicit disrespect for one’s own sociological reference group” (Perlmutter, 1954, p. 293).

³ Affect itself is commonly seen as an “umbrella term for a set of more specific mental processes including emotions, moods [. . .] thus, affect might be considered a general category for mental feeling processes” (Bagozzi, Gopinath, and Neyer, 1999, p. 185). While cognition is, in general, equated with beliefs, affect equates with feelings (Baloglu and Brinberg, 1997).

⁴ Internationalism is described as a concern about other nations’ welfare and empathy for people of other countries (Kosterman and Feshbach, 1989).

⁵ The *country image construct* is defined as “the total of all descriptive, inferential and informational beliefs one has about a country” (Martin

and Eroglu, 1993, p. 193).

⁶ The *product country image construct* is defined as “consumers’ perceptions about the attributes of products made in a certain country” (Netemeyer, Bearden, and Sharma, 2003, p. 388).

global marketing ethics

Bodo B. Schlegelmilch

Global marketing ethics can be defined as *standards of conduct and moral judgment applied to the field of global marketing* (see GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES). As such, it is tightly interwoven with business ethics, in general, and marketing ethics, in particular. Notwithstanding the fact that business ethics has long been a central issue for many famous economists like Adam Smith, Max Weber, Frank Knight, and Friedrich August von Hayek, *marketing ethics* has played only a minor role in business schools and marketing journals until the 1960s (see MARKETING'S CORPORATE RESPONSIBILITY). The topics addressed during this period were primarily of a general nature, dealing with corporate ethical decision making or norms and codes, although some subfunctions of marketing were also debated at this early stage, including ethics in product management (see PRODUCT-LINE STRATEGIES; GLOBAL PRODUCT DEVELOPMENT), ethical issues in marketing research (see ETHICS IN MARKETING RESEARCH), or ethics in advertising (see INTERNATIONAL ADVERTISING – IS THERE STILL A STANDARDIZATION VERSUS LOCAL ADAPTATION DEBATE?).

However, it took until the 1980s for *global marketing ethics* to attract wider attention. Given that the international aspects of marketing ethics cause some of the most vexing dilemmas, this is remarkable. The early articles focusing specifically on international aspects of ethics were mainly comparative studies (see UNDERSTANDING COMPARATIVE MARKETING SYSTEMS THROUGH CHANNEL MAPPING). For example, Becker and Fritzsche (1987) contrasted ethical behavior of American, French, and German managers while Schlegelmilch (1989) discussed the ethics gap between the United Kingdom and United States. A literature review covering most of these contributions has been published by Tsalikis and Fritzsche (1989). Among the early books focusing on international aspects of business ethics is Donaldson's (1989) *The Ethics*

of International Business. The increased focus on ethical issues in an international context also coincided with the launch of two specialized journals in the early 1980s, namely, the *Journal of Business Ethics* and the *Business & Professional Ethics Journal*.

The 1990s then witnessed a major expansion of the field. Contributions focused on a wide variety of international marketing issues like global marketing communication practices, ethical issues in international marketing research (see ETHICS IN MARKETING RESEARCH), price discrimination between international markets (see INTERNATIONAL PRICING OBJECTIVES AND STRATEGIES), counterfeits, use of corporate codes in an international marketing environment, and bribery. The first book exclusively devoted to *international marketing ethics*, was also published in the 1990s (Schlegelmilch, 1998).

Since 2000, the number of contributions on international marketing ethics increased substantially and the topics covered became more diverse. Issues as varied as ethical sensitivity to stakeholder interests across cultures (see MARKETING ASPECTS OF CULTURAL DISTANCE), international marketing ethics from an Islamic perspective, or the role of moral intensity and personal moral philosophies in the decision making of international marketers were discussed. While the large majority of previous contributions looked at ethical issues from a corporate vantage point, research now increasingly focuses on international marketing aspects through the lenses of consumers (see OPPORTUNITIES AND CHALLENGES IN SOCIAL MARKETING; ENVIRONMENTAL CONSUMER BEHAVIOR). Examples include comparisons of consumer ethics in different countries, attempts to draw up a typology of international consumers' ethical beliefs, or cross-cultural studies of the role of religion in consumers' ethical positions. A review of research focusing on marketing ethics was published by Nill and Schibrowsky (2007).

Taken collectively, international marketing ethics is still a relatively young and fragmented field. Given the growing interconnectedness of international markets, the increasing demands for corporate social responsibility, and the

ongoing calls for sound ethical leadership, more research in this area is needed.

consumer world-mindedness

Susan P. Douglas and Edwin J. Nijssen

DEFINITION

Consumer world-mindedness concerns an individual's interest in, openness to, and adoption of consumer products, services, and ideas from other cultures or parts of the world and accepting these cultures' norms and values completely and without *nationalistic bias or prejudice*. This follows Hannerz's (1990) view of a world-minded individual as one who has a predisposition toward a willingness to engage with the "other," and hence openness toward divergent cultural experiences, and a search for contrasts rather than for uniformity.

A world-minded person is someone with "positive respect for the culture and attainments of other races and peoples, an eagerness to know more about them, and a willingness to cooperate with them" (Fisher, 1926). World-minded individuals and consumers typically are more *interested in international media* and foreign travel and have a more developed international social network than their locally oriented counterparts (Beckmann *et al.*, 2001). In addition, world-minded consumers are willing to *try out and experiment* with products and brands from other cultures to get to know and experience these cultures. They have a genuine openness and interest in other ideas and products, and as a result, have more positive attitudes toward foreign products and are more likely to purchase them.

THEORETICAL ROOTS AND RELATED CONCEPTS

"World-mindedness" has its origins in Socrates' concept of a "world citizen" and was first conceptualized empirically in the social science literature by Sampson and Smith (1957). They distinguish between international-mindedness and world-mindedness. *International-mindedness* is viewed as relating to interest in and knowledge about international affairs. The concept of world-mindedness in contrast, designates an individual who favors a worldview on problems, and whose primary reference group is mankind

rather than Americans, English, Chinese, and so on. A world-minded individual is, therefore, likely to be concerned with human and animal rights, as also with poverty in emerging countries, world environment, and ecology.

Another related concept is that of *cosmopolitanism*. The concept of cosmopolitanism has been used in sociology. According to Merton (1957), a cosmopolitan is one who maintains a broad network of links and personal contacts outside the immediate community, while a localite is one whose universe and interests center on the local community. Hannerz (1990) further developed this concept, and conceptualized cosmopolitanism as a state of readiness or personal ability to make one's way into other cultures, accepting them completely and without prejudice. An in-depth study by Thompson and Tambyah (1999) views cosmopolitanism as the experience of an expatriate adapting to the lifestyle and mores of another country/culture without wholly abandoning his/her own. However, this latter view does not incorporate the adaptability of an individual to adapt to the world and its cultures in a broader sense, which as is the essence of world-mindedness.

OPERATIONALIZATION

Empirical studies in marketing typically rely on scales developed in other disciplines to measure world-mindedness or cosmopolitanism, but are generally not adapted to the consumer context. Sampson and Smith's (1957) 32 item scale of world-mindedness (or parts thereof) – relating to eight concepts, that is, religion, immigration, government, economics, patriotism, race, education, and war – is most often used for measuring consumers' world-mindedness. An exception is an instrument developed by Cannon *et al.*, (1994) to profile a cosmopolitan based on items relating to community and organizational commitment as well as their tendency to define themselves in a broader world context. The scale was refined in a multicountry study by Yoon, Cannon, and Yaprak (1996), but the dimensionality and reliability of the scale remains open to question given low factor scores and reliabilities.

2 consumer world-mindedness

Nijssen and Douglas (2008) developed a two-dimensional second-order scale for operationalizing consumer world-mindedness, conceptualizing consumers' cultural openness, and cultural adaptability to products and services from other cultures as *formative indicators* of the underlying phenomenon. Differing from previous attempts drawing on Sampson and Smith, these authors have defined and adapted the construct to the consumer level and context.

global product R&D

Aysegül Özsoy

Global Product R&D refers to a firm's attempt to concentrate and coordinate its product-related R&D activities in a few countries (Porter, 1986; Zou and Özsoy, 1999). This means that R&D activities are undertaken with a focus on multiple customer groups from multiple types of markets (e.g., advanced and emerging). The development of products (and services) for the simultaneous consumption of multiple markets and multiple segments are strategic imperatives in a globalizing environment (see GLOBAL PRODUCT DEVELOPMENT).

Concentration enables a firm to benefit from the *location advantages* associated with different countries and coordination exploits cross-country synergies. *Coordination* captures the process of integrating product-related R&D across different subsidiaries around the world. A high level of coordination means that R&D activities are linked tightly across countries. Concentration refers to the conduct of product R&D activities only in a handful of countries (Zou and Cavusgil, 1996). A firm can choose to concentrate product R&D activities or it can choose to disperse them so that they are being replicated in many countries. The dispersed activities can still be highly coordinated via formal (e.g., IT intranets, frequent reporting) and *informal coordination* mechanisms (e.g., brainstorming sessions, frequent visits, multicountry teams).

There are two critical strategic concerns in implementing a global product R&D: (i) in which countries should the R&D activities be located so that location advantages (see MARKET ENTRY AND EXPANSION) can be exploited? (ii) How should these R&D activities be linked and coordinated to benefit from cross-country synergies (Porter, 1986; Roth, 1992)? Proper location selection or configuration allows the firm to exploit the comparative technological advantages of multiple countries, so that maximum effectiveness and efficiency can be attained (see COMPETITIVE ADVANTAGE). Coordination, on the other hand, establishes concerted action among R&D activities and is critical in managing interdependence between

R&D activities and R&D centers. Coordination also enhances cross-country learning and scope benefits (Roth, 1992).

The shift to global product R&D by many multinational companies (MNCs) has led to the emergence of global *R&D Networks*. In addition to absolute increases in cross-border product R&D investments since the 1980s, the roles played by overseas R&D centers has changed from primarily transferring R&D from the parent company to the host country and adapting the product to the host country (see STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY) to that of a center for the development of product innovations for the *local*, *regional*, and *global markets* (Birkinshaw, Hood and Jonsson, 1998). Some of these product R&D centers have become "*Centers of excellence*" for MNCs.

The primary drivers of global product R&D networks are *differentiation* and division of labor. Different centers work on different product projects or on different activities for the same project leading to increased *specialization*. Such differentiation makes integration and coordination even more critical. It is possible that the benefits of global product R&D are related to the type and development stage of a technology. In industries characterized by rapid, radical innovations (see RADICAL INNOVATION), as opposed to incremental innovations (see INNOVATION TYPOLOGIES) and high uncertainties, the flexibility and speed enabled via global product R&D networks are critical.

The function of global product R&D may be related to whether product R&D is more *exploratory*, capturing search, variation, risk taking, experimentation, play, flexibility, discovery, and radical innovation, or whether it is more *exploitative*, capturing refinement, choice, production, efficiency, implementation, execution, and incremental innovation (March, 1991). When the function is more an exploratory global product R&D, interorganizational collaborations such as *partnerships* and *strategic alliances* are commonly resorted to in order to offset the higher risks and distant returns of the projects.

A critical research stream in global product R&D is *location selection* (see MARKET ENTRY

AND EXPANSION). Recent evidence in biotechnology and nanotechnology reveals that as research moves from *basic* to *applied*, the technological diversity, scientific strength, and scientific excellence of the host country are significant in attracting global product R&D centers of MNCs (Fernández-Ribas and Shapira, 2009). By contrast, the influence of local market-driven factors such as market size (Vernon, 1966) is less clear.

product ethnicity

Jean-Claude Usunier

Some products are typically associated with a particular country of origin, others are associated with several countries (e.g., cars with Germany, Japan, USA), while most products are not associated with specific countries. Products may be linked to a country because of its location, climate, or natural resources, or because of traditional manufacturing know-how (see "COUNTRY OF ORIGIN" AS BRAND ELEMENT). Countries also become associated with products because they are known as *place of invention*, *transformation*, or *use* (e.g., tea for England), or home to a brand associated with this country through its language (Leclerc, Schmitt, and Dubé, 1994).

These associations, dubbed by Roth and Romeo (1992) as *product-country matches*, may change consumer perception. A country considered as a poor origin, in general, may be viewed more positively when the particular product is associated with this country. Product ethnicity refers to the stereotypic association of a generic product with a particular country of origin (see CONSUMER CATEGORIZATION). Consumers from different countries may not make the same product \Rightarrow country or country \Rightarrow product associations. Thus, one may refer to the French product ethnicity of wine for German consumers, or to the Australian product ethnicity of wine for British consumers. Ethnicity in "product ethnicity" refers to a country (or several countries) being perceived as a legitimate place for the design, manufacturing, or consumption of a generic product (see PRODUCT CATEGORY). Countries may be associated with particular products given as stimuli (i.e., *product \Rightarrow country associations*) or products may be associated with particular countries given as stimuli (i.e., *country \Rightarrow product associations*). Product ethnicity occurs when an association reaches a certain level both ways. *Global product ethnicity* (GE), is based on country \Leftrightarrow product matches that are shared cross nationally. GE reflects the extent to which product \Leftrightarrow country associations are: (i) bidirectional and strong (i.e., most consumers make the association both

ways), (ii) quasi-exclusive (i.e., the product is significantly associated with a single or very few countries-of-origin), and (iii) cross national or global (i.e., a particular country \Leftrightarrow product association is shared worldwide). Usunier and Cestre (2007) indicate how to calculate GE from associations made by respondents between products and countries (and vice versa).

Product \Rightarrow country associations have been shown to be related to consumer product familiarity and product involvement (see CONSUMER INVOLVEMENT), while country \Rightarrow product associations are related to country familiarity (Usunier and Cestre, 2007). As people are more familiar with their own country than with others, consumers from a particular country associate their country more frequently than other countries with product stimuli. Likewise, local consumers tend to associate more products with their own country than with other stimulus countries because they are exposed to local manufactures and brands (see PERCEPTION OF BRAND EQUITY), and they are more knowledgeable about and familiar with domestic products. Self-centered country \Leftrightarrow product associations reflect a positive "domestic country bias," in favor of one's own country and domestic products (Balabanis and Diamantopoulos, 2004). Such self-centered association tendencies have been shown to be stronger in individualist countries than in collectivist countries (Usunier and Cestre, 2007). Finally, consumer willingness to buy a particular product is positively related to the degree of congruence between its country of origin and its product ethnicity. Consequently, global marketers (see GLOBAL MARKETING STRATEGY; GLOBAL MARKETING STRATEGY: PERSPECTIVES AND APPROACHES; GLOBAL BRANDING: THREE KEYS FOR GLOBAL BRAND SUCCESS) should always assess the degree of product ethnicity for the product category for which a specific marketing strategy is being developed.

born global

Gary Knight

“Born globals” are companies that conduct international business at or near the founding of the firm (Knight and Cavusgil, 1996, 2004; McKinsey and Company, 1993; Rennie, 1993). Despite the limited resources that usually characterize new businesses, born globals achieve substantial international sales from an early stage in their development. The period from domestic establishment to initial foreign market entry is often three or fewer years. Since the late 1980s, born globals have emerged in substantial numbers worldwide and have become relatively common among internationally active firms (see MARKET ENTRY AND EXPANSION). Historically, international business was mainly undertaken by large, well-resourced multinational enterprises (MNEs). The widespread appearance of born globals has revolutionized the traditional character of international business and holds important implications for the global economy.

Born globals are also known as *international new ventures*, which are defined in the scholarly management literature as “business organizations that, from inception, seek to derive significant competitive advantage from the use of resources and the sale of outputs in multiple countries” (Oviatt and McDougall, 1994). Given their youth, born globals tend to be relatively small firms and thus, usually have far fewer financial, human, and tangible resources than large MNEs. As the *internationalization* of born globals occurs shortly after founding, the origins of such firms are strongly international. Managers in these firms commit significant organizational resources to international activities. Born globals tend to be formed by entrepreneurs with a significant global orientation and often with strong international marketing skills (see GLOBAL MARKETING STRATEGY).

Born globals have been observed and described in virtually all major trading countries (OECD, 1997), across industry sectors (Knight and Cavusgil, 2004), and in both high- and low-tech industries (Madsen and Servais, 1997; Rennie, 1993). Historically, in many countries, it was believed that firms had to

build a strong domestic base before venturing into foreign markets (see STRATEGIC EXPORT MARKETING—ACHIEVING SUCCESS IN A HARSH ENVIRONMENT). One reason was the high fixed costs of entering a new market at a distance, including the costs of gaining market information and of managing agents or representatives to establish effective sales organizations (see INTERNATIONAL MARKETING CHANNELS). However, dramatic changes in recent decades – primarily globalization and the emergence of key technologies in information, communication, and transportation – are facilitating the ability of companies to compete internationally in the earliest days after the founding of the firm (see DIGITAL MEDIUM AND GLOBAL MARKETING; FORCES AFFECTING GLOBAL INTEGRATION AND GLOBAL MARKETING).

Born globals are associated with the emergence of a new scholarly field, INTERNATIONAL ENTREPRENEURSHIP, which has been defined as a combination of innovative, proactive, and risk-seeking behaviors that crosses national borders and aims to create value in organizations (McDougall and Oviatt, 2000). The field emphasizes two principal streams of scholarly research: the growing international role played by young entrepreneurial firms (born globals) and the international, entrepreneurial activities of established firms (Zahra and George, 2002). In this way, research on born global firms is leading to findings on organizational behaviors and approaches that firms of any age can employ to undertake entrepreneurial international ventures.

export assistance programs

Esra F. Gencturk

DEFINITION OF EXPORT ASSISTANCE PROGRAMS

The phrase *export assistance programs* refers to all public measures designed to encourage and assist exporting activities of individual firms and/or specific domestic industries. Almost all governments have a strong incentive to promote national exports in order to improve the international competitive advantage of domestic firms and hence the country's balance of trade. From a firm's perspective, such programs foster a pro-exporting attitude, facilitate development of necessary contacts, and provide assistance with specific exporting problems. Accordingly, variety of export assistance programs have been developed by governmental organizations to provide local firms/industries with support necessary for successful foreign market entry and expansion (*see* MARKET ENTRY AND EXPANSION) and to enhance their export performance (*see* EXPORT PERFORMANCE).

TYPES OF EXPORT ASSISTANCE PROGRAMS

Export assistance programs may be in many different forms ranging from counselling, tax incentives, and export financing to trade shows and sales leads. The kind of assistance that can be provided is restricted by the World Trade Organization (WTO) and as a result, government support typically manifests itself in a wide range of backup services (Diamantopoulos, Schlegelmilch and Tse, 1993). These services take different forms in different countries depending on a country's trade policy and its views toward government intervention in the business sector.

Apart from such differences, export assistance programs can be divided into indirect and direct services. The indirect services include all types of government support which are not specifically designed for exports but generate positive spillovers for export activity. These include productivity, R&D, and innovation support programs as well as general tax/investment incentive policies. The direct services, on the

other hand, include all programs designed to enhance export activity and competitiveness. These direct services are, in turn, grouped into (i) financial activities, (ii) information services, and (iii) export facilitating activities (Albaum, Duerr and Strandskov, 2005; Hollensen, 2007).

Financial activities. Export assistance programs involving financial supports for exporting are direct government attempts to make exporting more attractive on economic grounds. They also include attempts to encourage greater participation in exporting, particularly by smaller firms. Granting of subsidies fall under this subgroup. While subsidies given only to exports would be a violation of WTO regulations, general subsidies may still enable domestic producers to become price-competitive overseas. However, provision of such subsidies not only results in threats of direct retaliation but may also lead to dumping investigations in foreign markets where subsidized exports adversely affect the local manufacturers. Apart from subsidies, tax benefits are also used to encourage exporting. While the nature and extent of tax benefits given to exporters varies from country to country, they include deferred taxes on export earning, long-term tax holidays for export profits, and low export-profit tax rates. National governments also encourage exporting through their credit policy and credit insurance programs. These programs include credit facilities to cover working capital needs of exporters as well as subsidies and guarantees for export credits offered through commercial banks. Credit insurance and guarantees also cover certain commercial and political risks associated with a given export transaction.

Information services. National governments are a critical source of much of the basic information upon which exporting decisions are based. Examples of government information services, based on primary or secondary data relevant for exporters, include country data, reports on foreign firms, OPPORTUNITY IDENTIFICATION bulletins, information on relevant home and host-government regulations, and identification of potential foreign buyers/distributors for various products in different countries.

2 export assistance programs

Export facilitating activities. National governments also organize and sponsor activities in order to assist firms in tapping opportunities in foreign markets and expanding their foreign market coverage. These export facilitating activities include operating trade development offices or trade centers abroad, sponsoring trade missions, organizing trade fairs and exhibitions, and establishing free trade zones, free ports and/or export processing zones.

international relationship marketing

Jaqueline Pels

INTRODUCTION

“Relationship Marketing: Shift or Shaft” was the provocative title of Jag Sheth’s welcome speech during the Relationship Marketing Research Conference, at Emory University, back in 1996. Four years later, in the Handbook of Relationship Marketing (Sheth and Pravatiyar, 2000), in their last chapter, the authors addressed this challenging question repositioning it as “will it become a discipline out of a domain?” (p. 610). They avoided giving a clear answer and highlighted, instead, a set of challenges that relationship marketing needed to overcome, such as delimiting the domain, agreeing on a definition, developing a set of performance metrics, among others.

Almost 15 years later, the question still does not have an answer. Interestingly, a recent content analysis of the major business marketing journals (Dant and Lapuka, 2008; LaPlaca, 2008) shows that the share of articles dealing with relationships has increased consistently since 2000, whereas the relative number of articles on buying behavior, selling and sales management, and segmentation has been declining since the early 1990s. By studying the scholarly debates and the papers that have been published on this topic, it could be argued that there seems to be an academic shift toward relationship marketing. The question that needs to be addressed is this: “Is this shift occurring at a managerial level and, more specifically, is it an international trend?”

WHAT DOES THE INTERNATIONAL EMPIRICAL DATA SAY?

The Contemporary Marketing Practice (CMP) group has developed a strong conceptual classification scheme (Coviello *et al.*, 1997; Pels *et al.*, 2000; Brodie *et al.*, 2006), as well as, a consistent body of empirical studies¹ involving several years (1997–2007) and multiple countries from Europe (e.g., UK, Germany, Finland, Sweden, Ireland, Spain, Russia), North America (e.g., Canada, USA), South America (e.g., Chile,

Argentina, Uruguay), Asia (e.g., China, Thailand, New Zealand), and Africa (e.g., Ghana, Ivory Coast).

Brodie *et al.* (2008), in their history of the CMP project, describe how it was born as a result of a group of New Zealand researchers’ perceived tension between theory and practice. Thus the program’s objective was to *profile marketing practice in a contemporary environment, and to examine the relevance of relational marketing in different organizational, economic, and cultural contexts*. The final aim was to develop an understanding of how firms relate to their markets in a manner that integrates both traditional and more modern views of marketing. A classification scheme was developed that identified a typology of four² marketing practices: transaction marketing (*see* MARKETING MIX), database marketing (*see* INTERNAL DATABASES FOR MARKETING RESEARCH; DATABASE MINING AND MARKETING), interaction marketing (*see* INTERNATIONAL BUSINESS-TO-BUSINESS MARKETING), and network marketing.

In their article, Coviello *et al.* (2002) shift the analysis from “fitting data into the typology” to “allowing the data to speak.” The authors applied a cluster analysis and suggested a taxonomy of three marketing practices: a transactional cluster, a relational cluster, and a transactional/relational cluster (*see* Table 1). When replicated for Latin America (Pels and Brodie, 2003; Pels *et al.*, 2004), for Russia (Wagner, 2005), and for Ghana and Ivory Coast (Dadzie *et al.*, 2008) (*see* EMERGING MARKETS) a fourth cluster was added to the initial CMP taxonomy – the low-marketing cluster (*see* Table 2).

CONCLUSION

Relationship marketing suggests a different way of understanding the environment (i.e., as networks rather than markets) and, as a result, a diverse way of interacting with it (i.e., through close, interactive exchanges in which value is cocreated by the parties involved). Both the academic as well as the managerial world have much to gain in studying and understanding these types of exchanges. Nevertheless, the empirical studies do not support a shift toward

international entrepreneurship

Nicole Coviello

Research in the area of international entrepreneurship (IE) stems in large part from McDougall's (1989) empirical study comparing domestic and international new ventures (INVs), and Oviatt and McDougall's (1994) seminal work, which provided a theoretical base for the study of INVs. *INVs* were defined as business organizations "that, from inception, [seek] to derive significant competitive advantage from the use of resources and the sale of outputs in multiple countries" (Oviatt and McDougall, 1994, p. 49). Thus, study in the emerging field of IE began with an interest in new ventures.

The first widely accepted definition of IE comes from McDougall and Oviatt (2000, p. 903). They defined *IE* as "... a combination of innovative, proactive and risk-seeking behavior that crosses national borders and is intended to create value in organizations." This was later revised to reflect theoretical advances in the parent discipline of entrepreneurship, particularly those pertaining to "opportunity." Consequently, *IE* was redefined as "... the discovery, enactment, evaluation, and exploitation of opportunities – across national borders – to create future goods and services" (Oviatt and McDougall, 2005, p. 540). By allowing for individual, group, and organizational levels of behavior, the field of IE was broadened from its early focus on new ventures to include the behavior of larger, more established firms and the concept of corporate entrepreneurship. This is consistent with Zahra (2005), who maintains that it is the firm's entrepreneurial actions and entrepreneurial qualities that are the major source of competitive advantage. Also found in the domain of IE are comparisons of entrepreneurial behavior in multiple countries and cultures (Coviello and Jones, 2004; Oviatt and McDougall, 2005).

Nevertheless, central to IE research is the INV. Successful INVs usually lack resources and, consequently, internalize few assets and focus on less costly governance mechanisms to control a greater percentage of vital resources than would mature organizations. Such governance mechanisms include network stru-

ctures and social control within cooperative relationships. Further, successful INVs gain foreign location advantages from private knowledge they possess or produce, and make it sustainable through one or more means of protection. These include imperfect imitability, licensing, networks, or patents (Oviatt and McDougall, 1994). As discussed by Zahra (2005), the INV assumptions and cognitions regarding markets and competition are different from those of well-established firms. INV theory also challenges the more risk-averse, constrained, and gradual patterns of internationalization posited by Johanson and Vahlne's (1977) process theory (Autio, 2005).

Also relevant is that Oviatt and McDougall (1994) conceptualized four types of INV: (i) export/import start-ups, (ii) multinational traders, (iii) geographically focused start-ups, and (iv) global start-ups. It is the latter form that has received the most attention, commonly referred to as the BORN GLOBAL (Knight and Cavusgil, 1996). Zahra (2005) suggests, however, that insufficient IE research has attended to the four different types of INV, their prevalence under different combinations of industry, market, firm, and entrepreneur-related conditions or changes (including learning) that occur in INVs over time.

Recent theoretical arguments provide a base for further research in IE. Examples include Dimitratos and Plakoyianniki (2003)'s work on the dimensions of international entrepreneurial culture, Jones and Coviello's (2005) development of a general model of entrepreneurial international behavior and Styles and Seymour's (2006) arguments that value is not only created but exchanged in the process of identifying and exploiting opportunities that cross national borders. Such developments reflect the richness of IE as a research area, and its position at the interface of many disciplines ranging from international business, entrepreneurship, and strategy to, for example, marketing, innovation, knowledge management, and learning theory.

international business-to-business marketing

Paul Matthyssens

International business-to-business (B2B) marketing can be conceived as “cross-border value creation and exchange processes in business markets.” These days, most B2B companies are engaged in some form or other of international marketing and selling – the so-called “outward” internationalization (Hollensen, 2007). Several factors trigger this internationalization process. The first trigger is the *delocalization of their customers*. In fact, clients are gradually moving their production operations to offshore locations (see OFFSHORING AND MARKETING). Suppliers often get requests for “client following” to remote countries and their traditional “Western” markets dry up. Business markets have become international markets and international customers claim the same level of service in all foreign locations.

A second driver is the *growth in international trade* and the opening up and development of new foreign markets. Foreign markets are growing rapidly and the WTO is facilitating entry in these markets (for a discussion on barriers, see EMBARGOES AND SANCTIONS). At the same time, national governments, trade associations, and chambers of commerce are often “pushing” their homegrown champions to consider expansion abroad (Hollensen, 2007).

The third trigger is the *internationalization and global coordination of the purchasing function* (see also GLOBAL SOURCING STRATEGY: AN EVOLUTION). Increasingly, purchasers from multinational companies seek global purchasing synergies. This way, local plants gradually lose their purchasing mandates. Suppliers might be forced to sell twice and at different levels: an international frame contract to the client’s central purchasing office abroad, and sales to the local plant in the supplier’s domestic market. Getting access to international headquarters might be very difficult for smaller “local” suppliers who might lack the necessary scale and references to respond to a call for quotation at the central level. International customers

often prefer to work with suppliers with streamlined service approaches, integrated supply chain management, and internationally standardized marketing policies and GLOBAL ACCOUNT MANAGEMENT: THE RATIONALE AND MOTIVATION.

The fourth trigger is the *growing importance of international networks* (Harris and Wheeler, 2005). Solution providers (Helander and Möller, 2007) and value innovators (Matthyssens *et al.*, 2006) in B2B markets often rely on international partners for complementary competences. However, seeking good global partners and managing cross-border alliances turns out to be very challenging.

The fifth driver for increased internationalization is the intensified use of *electronic forms of exchange* (Samiee, 2008). Today, the Internet is a key facilitator for identifying suppliers or customers, negotiating, activating communities, establishing e-market places, and so on. Although entry and expansion in the international market are made much easier this way, B2B relationships might be more difficult to manage in the electronic highway (Samiee, 2008).

Because of these drivers, B2B companies recognize that international activities are fundamental to their performance (Katsikeas, 2006), and they start internationalizing earlier in their development (the so-called “BORN GLOBAL”, Rialp *et al.*, 2005) and they expand internationally at a high speed. Insufficient resources lead B2B marketers to use intensely international networks.

The higher degree of internationalization puts pressure on B2B companies. They face the challenge of coordinating and streamlining their marketing processes and programs across countries and regions. They must seek global synergies in an effort to control costs and eliminate inconsistencies in their marketing approaches, while simultaneously being forced to be responsive to local habits (read further in see STANDARDIZATION/ADAPTATION OF INTERNATIONAL MARKETING STRATEGY). The result is a subtle marketing strategy approach of combined adaptation, aggregation, and arbitrage (Ghemawat, 2007).

smuggling

Kate Gillespie

Smuggling encompasses the import or export of goods in violation of domestic or international law. Most smuggling, however, involves the illegal import of goods that face import quotas, significant tariffs, or other high taxes (*see* EMBARGOES AND SANCTIONS).

During the mid-nineteenth century, most developing countries employed strict quotas or enacted high tariffs on imports to protect local industries. These policies limited product choice and increased prices on many products. As a result, smuggling of consumer products became widespread. Smugglers evaded quotas and avoided tariffs, thus providing consumers with more choices and cheaper prices. Smugglers co-opted law enforcement agents via bribery and utilized the many unlicensed street vendors of the developing world's informal economy for the retail distribution of smuggled products.

Trade liberalization in EMERGING MARKETS has decreased smuggling but has failed to eradicate it completely. Smugglers continue to avoid residual tariffs as well as other taxes that their legal counterparts are subject to such as income taxes, sales taxes, value-added taxes, and sin taxes. Some smugglers, in the face of trade liberalization, have decreased costs by shifting from the smuggling of legally purchased goods to the smuggling of stolen or counterfeit goods (Gillespie and McBride, 1996). Furthermore, as customs authorities in many countries improve their ability to identify and confiscate shipments of counterfeits, many counterfeiters are forced to employ smuggling channels to circumvent customs checks. Thus even in the third millennium, smuggling dominates trade between some countries (Golub and Mbaye, 2008).

Smuggling of common consumer products has come increasingly under the auspices of transnational organized crime. In the late 1990s, Colombian officials estimated that 45% of the imported consumer products sold in their country had been financed by the Black Market Peso Exchange, a nefarious institution in which smuggled goods help launder illicit drug money. Government attempts to eliminate smuggling have increased as a result of the consolidation

and criminal violence of smugglers (Gillespie, 2003). Nonetheless, smuggling remains hard to eradicate because of its organized nature, government corruption, and a lack of resources for law enforcement.

There are both benefits and disadvantages for producers of legitimate products that are smuggled. Smuggling works to their advantage when their products are barred from entering markets or when prohibitive taxation discourages purchase of those products. However, smuggling poses similar challenges to multinational corporations as do legal but unauthorized parallel imports or GRAY MARKETS. Owners of global brands (*see* GLOBAL BRANDING: THREE KEYS FOR GLOBAL BRAND SUCCESS) may suffer when smugglers undercut legitimate distributors, since legitimate distributors often provide greater oversight of product quality and deliver after-sales service. Relationships with strategic allies, such as licensees or joint-venture partners in local markets, can be undermined when contraband enters partners' markets and diminishes the legal sales of these partners. However, the line between legal importers of products and smugglers is often blurred, because legal importers may distribute smuggled goods as well. Similarly, smugglers may attempt to camouflage their activities by legally importing some portion of the products they distribute.

Despite the challenges smuggling poses for international marketers, multinational firms have been known not only to tolerate the smuggling of their products but to actively support such smuggling. In the case of the world's five largest tobacco companies, support of smuggling has included selling cigarettes to known smugglers, disguising contraband shipments, destroying records related to smuggled cigarettes, establishing international financial accounts to camouflage contraband earnings, and purchasing airtime on transnational media to provide advertising support for smuggled brands. Several national and provincial governments have sued such companies for tax evasion and also to recoup costs incurred by the governments' policing of smuggling (Gillespie, 2003). Issues of jurisdiction have made such law suits difficult to win, but tobacco companies have sometimes settled out of court for sums rumored to be as high as a billion

2 smuggling

dollars. Furthermore, as tobacco firms began to curtail supplies to distributors involved with smuggling, these distributors replaced the legitimate product with counterfeits. Thus smuggling ceased to be a major contributor to the profits of these companies and became, instead, a substantial threat to their sales and brands.

understanding comparative marketing systems through channel mapping

Matthew B. Myers and Joachim (Joe) Grass

INTRODUCTION

Despite a general increase in economic wealth worldwide, significant differences remain in levels of economic development throughout the globe. A disequilibrium of resource distribution is particularly evident in many transitional and developing economies (TDEs), which causes significant portions of the expanding population in many of these economies to “gradually shift into urban slums and create a proletariat” (Slater and Jenkins, 1979). Given the assumption that economic stability leads to social stability, and economic stability is only possible when stakeholders in a society have access to markets, understanding how to better distribute wealth in TDEs is a key factor in comparative marketing system research. Having said this, researchers have also failed to provide meaningful evidence relative to what type, or combination, of resource distribution is best suited to bring stability to markets and economies. Often, redistribution has been accomplished through either high tax levies, or worse, nationalization of properties. Instead, new perspectives within global marketing seek to employ the entrepreneur as the redistributive agent, specifically by supporting and utilizing the distribution function to facilitate more efficient and effective markets. Marketing, and especially distribution, is not only a function within individual firms or institutions, but rather part of the whole social process system of a society (Slater and Jenkins, 1979). According to the activist paradigm, which states that marketing is a stimulus of development, this means that marketing institutions can facilitate economic development (Taylor and Omura, 1994), and hence help remedy this condition.

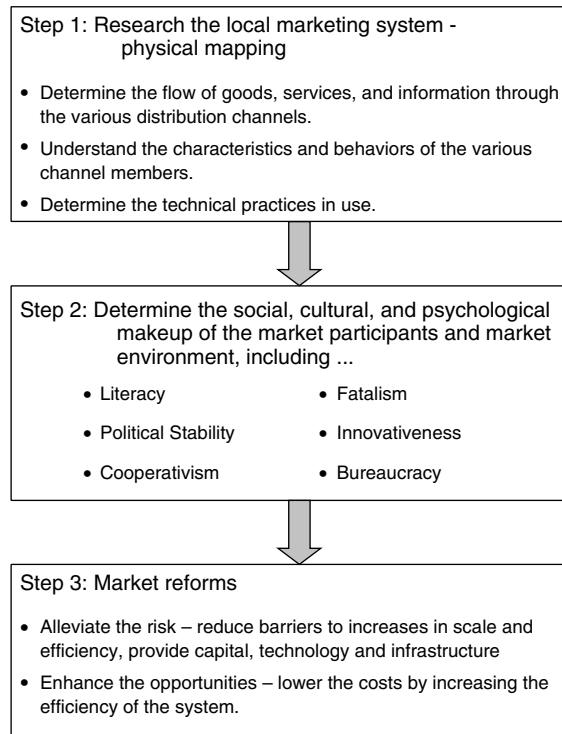

Various factors are important for business development in TDE countries and the subsequent competitive positions these markets may enjoy relative to more developed economies. First, price controls must be addressed. Second, levels of technological development must

be achieved. And third, infrastructure and distribution channel development must reach a point where the free flow of goods and services, and the corresponding redistribution of wealth internal to the market, takes place. It is the channel variable which spans a broad spectrum of issues ranging from availability of credit to natural resources (Albaum and Peterson, 1984). A useful yet underutilized tool for analyzing channels is “channel mapping” (Nason, 1993). Channel mapping identifies anomalies in a market’s distribution processes and is used to increase efficiencies in distribution systems as well as propose market reforms that will factor in cultural variables to minimize detrimental effects on the market. This is particularly important in transitional countries where command systems have customarily ignored critical aspects of the distribution process (Nason, 1993). This can lead to inefficient, inflexible, and poorly structured channels, which can hinder economic development of an area (Slater *et al.*, 1969), restrict individual participation in the economy, and restrict foreign direct investments (FDI). Most importantly, success of reforms is in part dependent on the inclusion of individuals (entrepreneurs) in improving distribution efficiency, this by performing warehousing, retail, logistics, or other functions key with moving goods to and from markets.

UNDERSTANDING MARKET DIFFERENTIALS THROUGH CHANNEL MAPPING

Analyzing comparative marketing systems in order to identify distribution anomalies may take place through a systematic process developed by Slater and described by Nason (1993). There are three steps required, starting with the analysis of a system and leading to market and policy reforms (see Figure 1).

Step 1: system analysis. The process starts with determining the flow of goods, services, and information through the various distribution channels, which helps identify and remedy inefficiencies in the system (such as insufficient or overabundance of middlemen, insufficient/deficient roads, raw materials, production and manufacturing, transportation, wholesale, warehousing, power relationships, consumers,

Adapted from: Nason and White (1981), Nason (1993)

Figure 1 The channel mapping process.

and credit). This causes prices to decline and purchasing power of consumers to increase. This step also calls for understanding the characteristics and behaviors of the various channel members, which is especially important in an international business context so that potential foreign investors can better understand the economic environment and thereby reduce their risk.

Step 2: social and cultural environment. The second step calls for an analysis of the social, cultural, and psychological make-up of the market participants and environment (such as literacy rates, achievement desires, cooperativism, fatalism, innovativeness, and gender roles). This is necessary to understand the expected business and social behaviors in a certain environment, as well as to understand possible repercussions across the society that result from market reforms and new

policies. From both standpoints (sociological and economic) it is important to understand barriers and perceived barriers of the channel participants.

Step 3: market reforms. The final step involves the creation of new policies and regulations that will (i) enhance the opportunities of the individual within the market through lowering costs (via increasing efficiencies), (ii) include an increasingly broad cross-section of the population in the value-added chain, and enhance the risk assessment capabilities for (domestic as well as international) business development.

Applications of the channel mapping method have been successful in a number of TDEs including Lesotho, Brazil, and Thailand. It is an effective method for identifying limitations on channel performance, creating greater participation in marketing functions and thus redistributing wealth, and focusing

developmental efforts at the micro- and macrosystem level on the most cost efficient rationalization strategies (Nason, 1993). Given the importance of economic and social stabilization worldwide, an increased understanding of the role of marketing distribution in the process of economic development is timely. Utilizing system comparisons such as channel mapping offers policymakers a viable option for market-friendly wealth redistribution, with benefits from the resulting increased participation in the marketplace.

offshoring and marketing

Neeraj Bharadwaj

BACKGROUND

Offshoring, which refers to the migration of value-chain processes once carried out in a given locale to another country,¹ has been deemed a practice likely to bring about transformational change in international trade (Blinder, 2006). Such a claim does not seem too far-fetched because many firms have readily transferred activities such as production, new-product development (*see* GLOBAL PRODUCT DEVELOPMENT), and pre- and post-sales assistance (*see* SERVICES MARKETING STRATEGY) to locations abroad, mainly enticed by the promise that offshoring will enable them to carry out these activities in the very same way, but at a lower cost (Friedman, 2005).²

Although some research in operations management (Gans, Koole, and Mandelbaum, 2003; Carmel and Tjia, 2005) as well as by prominent consulting firms (Farrell and Rosenfeld, 2005) suggests that offshoring has indeed assisted firms in reducing costs, the reality is that cost savings alone are unable to capture the full implications of the practice. That is because customers may perceive the quality of offshored “products” – be they goods and/or services – as subpar (Whoriskey, 2008). This is problematic because prior research has shown that a firm whose product/service quality is perceived as subpar is likely to encounter unfavorable customer evaluations and higher churn rates (Keaveney, 1995), which in turn, can have deleterious top-line revenue effects (Zeithaml, Berry, and Parasuraman, 1996).

It is therefore important to examine the research in marketing that has already investigated the impact of the geographic location cue on customer appraisals. It is also necessary to identify future projects that can be carried out to learn more about offshoring, customer appraisals, and cost savings.

OFFSHORING AND CUSTOMER APPRAISALS

The country of origin (COO) literature (*see* “COUNTRY OF ORIGIN” AS BRAND ELEMENT)

has studied the impact of the location cue on customer appraisals. In general, this body of knowledge demonstrates that favorable country perceptions yield favorable product/service evaluations, and advises that the location cue ought to be evaluated in conjunction with other cues (Peterson and Jolibert, 1995; Gurhan-Canli and Maheswaran, 2000). In one of the few studies to directly examine the influence of offshoring on customer appraisals, Roggeveen, Bharadwaj, and Hoyer (2007) build upon the COO literature to evaluate the effect of call-center location and firm reputation on customer expectations regarding an upcoming voice-to-voice service encounter. Those authors conclude that call-center location does not impact customer expectations regarding an upcoming service encounter if the firm is reputed; however, if the firm is less known, individuals anticipate being less satisfied if they believe the call center is located in a nation dissimilar to the United States (i.e., India or the Philippines) versus either similar to the United States (i.e., England) or in the United States.

OFFSHORING, CUSTOMER APPRAISALS, AND COST SAVINGS

More scholarly attention should be devoted toward understanding the outcomes of this widespread practice of offshoring. One possibility is to further examine the impact of the location cue on customer evaluations, where location could be operationalized along the lines of cultural distance (*see* MARKETING ASPECTS OF CULTURAL DISTANCE) between the customer’s home country and the country to which the business process is to be migrated. Bharadwaj and Roggeveen (2008) describe a methodology that can be utilized to evaluate situations in which the customer possesses greater familiarity with the culture to which a business is being migrated (i.e., “nearshoring”) compared to a less familiar one. A more challenging endeavor is to integrate thinking in operations and marketing to evaluate the extent to which the short-term cost savings from offshoring are offset by top-line revenue losses stemming from existing customers exiting relationships, buying less, and/or engaging in negative word-of-mouth behavior and from prospective customers being

put off by perceived product/service quality inadequacies. Such research that evaluates the trade-off between initial cost savings and long-term customer-related outcomes will provide insight into the conditions under which offshoring can truly serve as a basis for driving profitable growth.

ENDNOTES

¹ Bharadwaj and Roggeveen (2008) detail the conceptual distinction between offshoring (i.e., when a given business process is carried out somewhere else) and outsourcing (i.e., when a given process is carried out by someone else). Researchers must distinguish between these two closely related practices in order to understand their respective main and interaction effects.

² Another reason firms opt to engage in offshoring is to draw upon new employee skill sets available elsewhere (Venkatraman, 2004).

marketing strategy implementation

Robert E. Morgan

INTRODUCTION

A critical indictment of contemporary marketing practice is that “misguided marketing strategies have destroyed more shareholder value, and probably more careers, than shoddy accounting or shady fiscal practices have” (McGovern *et al.*, 2004, p. 70). The object of such derision would appear to be the MARKETING STRATEGY per se but, all too frequently, this conveys the symptom rather than the cause of poor marketing practice. As White, Conant and Echambadi (2003) observed, marketing strategy implementation (MSI) capability perfectly mediates the relationship between marketing strategy development style and firm performance. Consequently, MSI has become an important theoretical focus for researchers, a key performance indicator for marketing personnel, and a vital precursor to organizational effectiveness.

DEFINITION

Strategy implementation is traditionally considered as the “doing” stage in the MARKETING PLANNING process and follows the “dreaming” stage, commonly referred to as strategy formulation (Olson, Slater and Hult, 2005). Considered synonymous with marketing strategy execution, delivery, and transition, MSI can be defined as the *communication, interpretation, adoption, and enactment of a marketing strategy or strategic marketing initiative* (Noble and Mokwa, 1999, p. 57). Despite the fact that the normative literature has recently declared strategy implementation as the *sine qua non* of firm performance gains (Bower and Gilbert, 2007), the literature that underpins our academic knowledge of this concept reflects the embryonic stage of its theoretical development.

SCOPE OF THINKING

Figure 1 outlines the coverage of the strategy implementation literature from specifically the marketing domain.¹ This figure indicates the range of perspectives, influences, and foci that

have been employed in studying the multifaceted and complex organizational process of MSI.

Historically, studies initially focused on structural phenomena in seeking to explain successful MSI; these studies commonly adopted either the structure-conduct-performance framework or institutional theory (Walker and Ruekert, 1987). This was followed by a wave of studies that examined the interpersonal processes that underlie the implementation effort (Noble, 1999). Such investigations focused primarily on the problems and challenges encountered in MSI with the conclusions being that poor marketing performance could be attributable to the disconnect between the formulation of marketing strategy and its implementation (Piercy, 1998). This dichotomy leads to a fault line in the process of strategizing whereby the harsh realities of implementation are misunderstood by the idealizing that can be characteristic of formulation stage of the planning process. At this juncture in the development of MSI knowledge, a variety of lenses were employed which ranged from contingency explanations through to psycho-social theories (Chimhanzi and Morgan, 2005) and more mainstream resource-based approaches (Hughes and Morgan, 2008). Consequently, our developed in different ways but much of the research conducted examined the role of the individual/group or the behavioral and cultural processes that underpin MSI (Noble, 1999).

In a similar way, the level of analysis has changed over time. Initially focused on the top management team and chief marketing officer (Homburg, Workman and Krohmer, 1999), the role of the mid-level (marketing) manager became apparent as a key linchpin in delivering the implementation actions required of the marketing strategy (Thorpe and Morgan, 2007). More recently, the level of analysis has also included frontline employees and the role of the customer in delivering effective MSI for firms (Homburg, Wieseke and Bornemann, 2009).

The cascade of supporting actions and decisions required to realize marketing strategy means that there are inevitable implications at the tactical and operational level of the firm (Porter and Harper, 2003). Often overlooked, marketing actions at this level can have a seemingly disproportionate consequence on MSI.

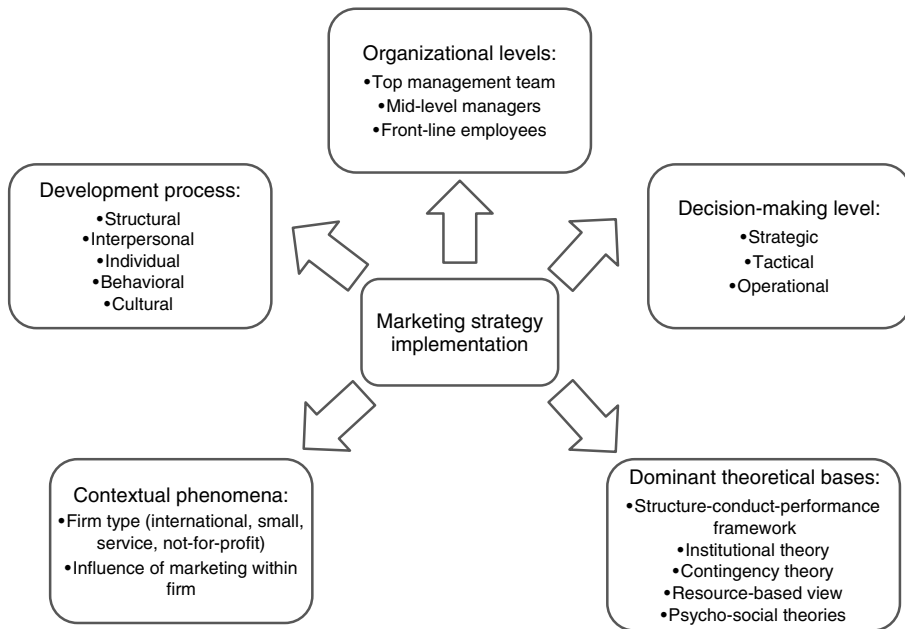

Figure 1 The main theoretical explanada underlying marketing strategy implementation.

Finally, MSI considerations remain as important for the multinational corporation as they do for other types of organizations from the small firm to the service-based enterprise and not-for-profit sector (Sashittal and Jassawalla, 2001).

OBSERVATIONS

There is overwhelming evidence to indicate that, provided marketing strategy is cogent, effective MSI can deliver performance gains for firms. Effective MSI derives from, among other factors, the appropriate organizational structures and administrative systems; control mechanisms; leadership style; employee incentives; communication efforts; integration and coordination arrangements; and, levels of strategy commitment and consensus. However, despite implementing a marketing strategy at one point in time, awareness needs to be given to the strategy dynamics at work which can significantly affect how optimum the strategy remains over time. A concept that is currently receiving considerably more attention by managers and researchers alike is strategic improvisation, which describes the

simultaneous formulation and implementation of a strategy implying a responsiveness and flexibility in planning which is unparalleled.

ENDNOTES

¹ Much of the literature associated with the concept of strategy implementation derives from the organizational behavior, administrative science, public policy, technology, strategy and marketing disciplines. There is significant cross fertilization of theoretical ideas and applications among the literatures pertaining to implementation issues, processes, and contexts. This discussion is devoted specifically to sources within the marketing domain and observations that derive from empirical studies of marketing strategy.
